# 32-Channel Sample/Hold Amplifier with Four Multiplexed Inputs 

## General Description

The MAX5166 contains four 1-to-8 multiplexers and 32 sample/hold amplifiers. The sample/hold amplifiers are organized into four octal sample/holds with separate inputs and independent TTL/CMOS-compatible hold enables for each octal set. Additional 3-bit TTL/CMOScompatible address logic selects the 1-to-8 multiplexer channel. The MAX5166 is available with an output impedance of $50 \Omega, 500 \Omega$, or $1 \mathrm{k} \Omega$, allowing output filtering.
The MAX5166 operates with +10 V and -5 V supplies, and a separate +5 V digital logic supply. Manufactured with a proprietary BiCMOS process, it provides high accuracy, fast acquisition time, low droop rate, and a low hold step. The device acquires 8 V step input signals to $0.01 \%$ accuracy in $2.5 \mu \mathrm{~s}$. Transitions from sample mode to hold mode result in only 0.5 mV of error. While in hold mode, the output voltage slowly droops at a rate of $1 \mathrm{mV} / \mathrm{sec}$. The MAX5166 is available in a 48-pin TQFP package.

## Applications

Automatic Test Systems (ATE)
Industrial Process Controls
Arbitrary Function Generators
Avionics Equipment

Features

- Quad, 8-Channel Sample/Hold
- 0.01\% Accuracy of Acquired Signal
- 0.01\% Linearity Error
- Fast Acquisition Time: 2.5 $\mathbf{~ s}$
- Low Droop Rate: 1mV/sec
- Low Hold Step: 0.25mV
- Wide Output Voltage Range: +7V to -4V

## Detailed Description

The MAX5166 connects four separate analog inputs to four internal 1-to-8 analog multiplexers. Each multiplexer channel connects to a buffered sample/hold circuit and a series output resistor, creating a four-input device with 32 sample/hold output channels. Three multiplexer channel-address inputs and four modeselect inputs (one for each multiplexer) control channel selection and sample/hold functions (Figure 1 and Tables 1 and 2).

## Digital Interface

Three address pins and 3 -to- 8 address decoder logic select the channel for all four internal analog multiplexers. The mode-select inputs (M3-M0) independently control the sample/hold functions for each multiplexer (Tables 1 and 2).

## Sample/Hold

The MAX5166 contains 32 buffered sample/hold circuits with internal hold capacitors. Internal hold capacitors minimize leakage current, dielectric absorption, feedthrough, and required board space. The value of the hold capacitor affects acquisition time, hold step, and droop rate. Lower capacitance allows faster acqui-
sition times but increases the droop rate. Higher values increase hold time and acquisition time. The hold capacitor used in the MAX5166 provides fast $2.5 \mu \mathrm{~s}$ (typ) acquisition time while maintaining a low $1 \mathrm{mV} / \mathrm{sec}$ (typ) droop rate, making the sample/hold ideal for highspeed sampling.

## Sample Mode

Driving M3-M0 low (one at a time) selects sample mode (Tables 1 and 2). During sample mode, the selected multiplexer channel connects to $\mathrm{IN}_{\text {_ }}$ allowing the hold capacitor to acquire the input signal. To guarantee an accurate sample, maintain sample mode for at least $4 \mu \mathrm{~s}$. Sampling for longer than $4 \mu \mathrm{~s}$ results in tracking. Only the addressed channel on the selected multiplexer samples the input; all other channels remain in hold mode.

## Hold Mode

Driving M3-M0 high selects hold mode. Hold mode disables the multiplexer, which disconnects all eight channels on the 1-to-8 multiplexer from the input. When a channel is disconnected, the hold capacitor maintains the sampled voltage at the output with a $1 \mathrm{mV} / \mathrm{sec}$ droop rate (towards VDD).

# 32-Channel Sample/Hold Amplifier with Four Multiplexed Inputs 

## Table 1. Output Selection

| ADDRESS |  |  | OUTPUT SELECTED |  |  |  |

$0=$ Logic Low, $1=$ Logic High

## Table 2. Mode Selection

| MODE-SELECT <br> INPUTS* (M3-M0) | ACTION |
| :---: | :--- |
| 0 | Sample mode enabled on selected <br> analog multiplexer and channel <br> (Table 1). |
| 1 | Hold mode enabled on selected <br> analog multiplexer and channel <br> (Table 1). |

$0=$ Logic Low, $1=$ Logic High

* Only one $M_{-}$input asserted low; all others must be logic high to meet the timing specification (see Single vs. Simultaneous Sampling).

Hold Step
When switching between sample mode and hold mode, the voltage of the hold capacitor changes due to charge injection from stray capacitance. This voltage change, called hold step, is minimized by limiting the amount of stray capacitance seen by the hold capacitor. The MAX5166 limits the hold step to 0.25 mV (typ). An output capacitor to ground can be used to filter out this small hold-step error.

## Output

The MAX5166 contains an output buffer for each multiplexer channel ( 32 total), so the hold capacitor sees a high-impedance input, reducing the droop rate. While in hold mode, the hold capacitor discharges at a rate of $1 \mathrm{mV} / \mathrm{sec}$ (typ). The buffer also provides a low output impedance; however, the device contains output resistors in series with the buffer output (Figure 1) for selected output filtering. To provide greater design flexibility, the MAX5166 is available with an Ro of $50 \Omega, 500 \Omega$, or $1 \mathrm{k} \Omega$.

Note: Output loads increase the analog supply current (IdD and Iss). Excessive loading of the output(s) damages the device by consuming more power than the device will dissipate (see Absolute Maximum Ratings). The resistor-divider formed by the output resistor (ROUT_) and load impedance (RL) scales the sampled voltage (VSAMP). Determine the output voltage (VOUT_) as follows:

$$
\begin{gathered}
\text { Voltage Gain }=A V=R L /(R L+R O U T) \\
\text { VOUT_ }=\text { VSAMP } \cdot A V
\end{gathered}
$$

The maximum output voltage range depends on the analog supply voltages available and the scaling factor used:

$$
\left(V_{S S}+0.75 \mathrm{~V}\right) \cdot \text { AV }^{5} \leq \mathrm{V}_{\text {OUT }}^{-} \leq\left(\mathrm{V}_{\mathrm{DD}}-2.4 \mathrm{~V}\right) \cdot \mathrm{AV}
$$

when $R L=\infty$, then $A V=1$, and this equation becomes $\left(V_{S S}+0.75 V\right) \leq V_{\text {OUT }} \leq\left(V_{D D}-2.4 V\right)$.

## Timing Definitions

Acquisition time ( $\mathrm{t}_{\mathrm{AQ}}$ ) is the amount of time the MAX5166 must remain in sample mode for the hold capacitor to acquire an accurate sample. The holdmode setting time ( tH ) is the amount of time necessary for the output voltage to settle to its final value. Aperture delay (tap) is the time interval required to disconnect the input from the hold capacitor. The inhibit pulse width (tPW) is the amount of time the MAX5166 must remain in hold mode while the address is changed. The data setup time (tDS) is the amount of time an address must be maintained before the address becomes valid. The data hold time (tDH) is the amount of time an address must be maintained after mode select has gone from low to high (Figure 2).

## 32-Channel Sample/Hold Amplifier with Four Multiplexed Inputs

Figure 2. Timing Performance

## Applications Information

## Combining Inputs

The MAX5166 contains a separate input for each 1-to-8 multiplexer. Externally connect the input pins to form larger multiplexers. When all four inputs are connected to the same source, the MAX5166 is functionally equivalent to the MAX5165, except the MAX5166 does not contain output clamping diodes.

## Control-Line Reduction

The MAX5166 contains four separate 1-to-8 multiplexers and individual mode selectors for each multiplexer. When sampling one channel at a time, use an external 2-to-4 decoder (with active-low outputs) to reduce the number of digital control lines from seven to five (Figure 3).

## Single vs. Simultaneous Sampling

Individually control the four mode/multiplexer-select pins to simultaneously sample on four channels, the same channel for each multiplexer (Figure 4). Each mode-select pin controls sampling on one of the 1-to-8 multiplexers, while the 3-bit address selects one of the eight channels on all the multiplexers (Tables 1 and 2). Setting any combination of the mode-select pin low enables sampling on the addressed channels for the selected multiplexers.

Simultaneously sampling two or more channels reduces offset voltage but increases acquisition time. Multiply the single-channel acquisition time by the number of channels sampling.

Multiplexed DAC
Figure 5 shows a typical demultiplexer application. Different digital codes are converted by the digital-toanalog converter (DAC) and then stored on eight different channels, or as many as 32 different channels when all four inputs are active. The $100 \mathrm{mV} / \mathrm{sec}$ (max) droop rate requires refreshing the hold capacitors every 100ms before the voltage drops by 1/2LSB for an 8 -bit DAC with a 5 V full-scale voltage.

Powering the MAX5166
The MAX5166 does not require a special power-up sequence to avoid latchup. The device requires three separate supply voltages for operation; however, when one or two of the voltages are not available, DC-DC charge-pump (switched-capacitor) converters provide a simple, efficient solution. The MAX860 provides voltage doubling or inversion, ideal for conversions from +5 V to +10 V or from +5 V to -5 V . The MAX860 also functions as a voltage divider to provide conversion from +10 V to +5 V .
