

## 12MHz Rail-to-Rail Input-Output Op Amps

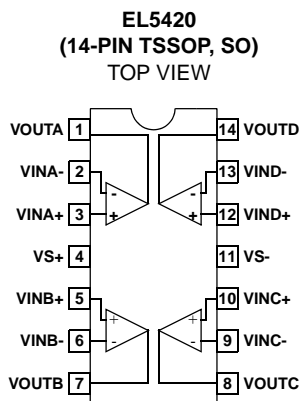

The EL5420 and EL5220 are low power, high voltage, rail-to-rail input-output amplifiers. The EL5220

contains two amplifiers in one package, and the EL5420 contains four amplifiers. Operating on supplies ranging from 5V to 15V, while consuming only 500µA per amplifier, the EL5420 and EL5220 have a bandwidth of 12MHz (-3dB). They also provide common mode input ability beyond the supply rails, as well as rail-to-rail output capability. This enables these amplifiers to offer maximum dynamic range at any supply voltage.

The EL5420 and EL5220 also feature fast slewing and settling times, as well as a high output drive capability of 30mA (sink and source). These features make these amplifiers ideal for use as voltage reference buffers in Thin Film Transistor Liquid Crystal Displays (TFT-LCD). Other applications include battery power, portable devices, and anywhere low power consumption is important.

The EL5420 is available in a space-saving 14-pin TSSOP package, the industry-standard 14-pin SO package, as well as a 16-pin LPP package. The EL5220 is available in the 8-pin MSOP package. Both feature a standard operational amplifier pin out. These amplifiers are specified for operation over the full -40°C to +85°C temperature range.

### Pinouts

### Features

- 12MHz -3dB bandwidth
- Supply voltage = 4.5V to 16.5V
- Low supply current (per amplifier) = 500µA
- High slew rate = 10V/µs
- Unity-gain stable
- Beyond the rails input capability
- Rail-to-rail output swing
- Ultra-small package

### Applications

- TFT-LCD drive circuits
- Electronics notebooks
- Electronics games
- Touch-screen displays
- Personal communication devices
- Personal digital assistants (PDA)
- Portable instrumentation
- Sampling ADC amplifiers
- Wireless LANs
- Office automation
- Active filters
- ADC/DAC buffer

**Applications Information**

**Product Description**

The EL5220 and EL5420 voltage feedback amplifiers are fabricated using a high voltage CMOS process. They exhibit rail-to-rail input and output capability, they are unity gain stable, and have low power consumption (500µA per amplifier). These features make the EL5220 and EL5420 ideal for a wide range of general-purpose applications. Connected in voltage follower mode and driving a load of 10kΩ and 12pF, the EL5220 and EL5420 have a -3dB bandwidth of 12MHz while maintaining a 10V/µs slew rate. The EL5220 is a dual amplifier while the EL5420 is a quad amplifier.

**Operating Voltage, Input, and Output**

The EL5220 and EL5420 are specified with a single nominal supply voltage from 5V to 15V or a split supply with its total range from 5V to 15V. Correct operation is guaranteed for a supply range of 4.5V to 16.5V. Most EL5220 and EL5420 specifications are stable over both the full supply range and operating temperatures of -40°C to +85°C. Parameter variations with operating voltage and/or temperature are shown in the typical performance curves.

The input common-mode voltage range of the EL5220 and EL5420 extends 500mV beyond the supply rails. The output swings of the EL5220 and EL5420 typically extend to within 80mV of positive and negative supply rails with load currents of 5mA. Decreasing load currents will extend the output voltage range even closer to the supply rails. Figure 1 shows the input and output waveforms for the device in the unity-gain configuration. Operation is from ±5V supply with a 10kΩ load connected to GND. The input is a 10V<sub>P-P</sub> sinusoid. The output voltage is approximately 9.985V<sub>P-P</sub>.

FIGURE 1. OPERATION WITH RAIL-TO-RAIL INPUT AND OUTPUT

**Short Circuit Current Limit**

The EL5220 and EL5420 will limit the short circuit current to ±120mA if the output is directly shorted to the positive or the negative supply. If an output is shorted indefinitely, the power dissipation could easily increase such that the device may be damaged. Maximum reliability is maintained if the output

continuous current never exceeds ±30mA. This limit is set by the design of the internal metal interconnects.

**Output Phase Reversal**

The EL5220 and EL5420 are immune to phase reversal as long as the input voltage is limited from (V<sub>S-</sub>) -0.5V to (V<sub>S+</sub>) +0.5V. Figure 2 shows a photo of the output of the device with the input voltage driven beyond the supply rails. Although the device's output will not change phase, the input's overvoltage should be avoided. If an input voltage exceeds supply voltage by more than 0.6V, electrostatic protection diodes placed in the input stage of the device begin to conduct and overvoltage damage could occur.

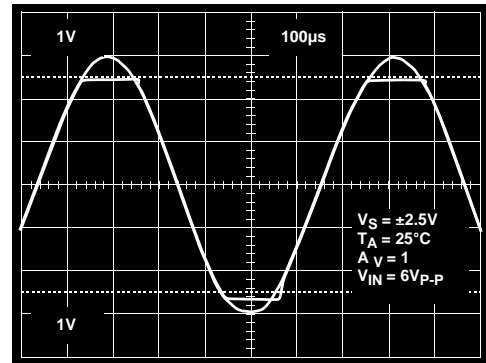

FIGURE 2. OPERATION WITH BEYOND-THE-RAILS INPUT

**Power Dissipation**

With the high-output drive capability of the EL5220 and EL5420 amplifiers, it is possible to exceed the 125°C “absolute-maximum junction temperature” under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if load conditions need to be modified for the amplifier to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to:

$$P_{DMAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}}$$

where:

T<sub>JMAX</sub> = Maximum Junction Temperature

T<sub>AMAX</sub> = Maximum Ambient Temperature

θ<sub>JA</sub> = Thermal Resistance of the Package

P<sub>DMAX</sub> = Maximum Power Dissipation in the Package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the loads, or:

$$P_{DMAX} = \Sigma i \times [V_S \times I_{SMAX} + ((V_{S+}) - V_{OUTi}) \times I_{LOADi}]$$

when sourcing, and:

$$P_{DMAX} = \sum i \times [V_S \times I_{SMAX} + ((V_{OUTi}) - V_S) \times I_{LOADi}]$$

when sinking.

where

$i = 1$  to 2 for Dual and 1 to 4 for Quad

$V_S$  = Total Supply Voltage

$I_{SMAX}$  = Maximum Supply Current Per Amplifier

$V_{OUTi}$  = Maximum Output Voltage of the Application

$I_{LOADi}$  = Load Current

If we set the two  $P_{DMAX}$  equations equal to each other, we can solve for  $R_{LOADi}$  to avoid device overheat. Figures 3, 4, and 5 provide a convenient way to see if the device will overheat. The maximum safe power dissipation can be found graphically, based on the package type and the ambient temperature. By using the previous equation, it is a simple matter to see if  $P_{DMAX}$  exceeds the device's power derating curves. To ensure proper operation, it is important to observe the recommended derating curves in Figures 3, 4, and 5.

FIGURE 3. PACKAGE POWER DISSIPATION VS AMBIENT TEMPERATURE

FIGURE 4. PACKAGE POWER DISSIPATION VS AMBIENT TEMPERATURE

FIGURE 5. PACKAGE POWER DISSIPATION VS AMBIENT TEMPERATURE

**Unused Amplifiers**

It is recommended that any unused amplifiers in a dual and a quad package be configured as a unity gain follower. The inverting input should be directly connected to the output and the non-inverting input tied to the ground plane.

**Driving Capacitive Loads**

The EL5220 and EL5420 can drive a wide range of capacitive loads. As load capacitance increases, however, the -3dB bandwidth of the device will decrease and the peaking increase. The amplifiers drive 10pF loads in parallel with 10kΩ with just 1.5dB of peaking, and 100pF with 6.4dB of peaking. If less peaking is desired in these applications, a small series resistor (usually between 5Ω and 50Ω) can be placed in series with the output. However, this will obviously reduce the gain slightly. Another method of reducing peaking is to add a “snubber” circuit at the output. A snubber is a shunt load consisting of a resistor in series with a capacitor.

Values of  $150\Omega$  and  $10\text{nF}$  are typical. The advantage of a snubber is that it does not draw any DC load current or reduce the gain.

### **Power Supply Bypassing and Printed Circuit Board Layout**

The EL5220 and EL5420 can provide gain at high frequency. As with any high-frequency device, good printed circuit board layout is necessary for optimum performance. Ground plane construction is highly recommended, lead lengths should be as short as possible and the power supply pins must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the  $V_{S-}$  pin is connected to ground, a  $0.1\mu\text{F}$  ceramic capacitor should be placed from  $V_{S+}$  to pin to  $V_{S-}$  pin. A  $4.7\mu\text{F}$  tantalum capacitor should then be connected in parallel, placed in the region of the amplifier. One  $4.7\mu\text{F}$  capacitor may be used for multiple devices. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used.
