

## 18-Channel TFT-LCD Reference Voltage Generator

The EL5525 is designed to produce the reference voltages required in TFT-LCD applications. Each output is programmed to the required voltage with 10 bits of resolution. Reference pins determine the high and low voltages of the output range, which are capable of swinging to either supply rail. Programming of each output is performed using the serial interface. A serial out pin enables daisy chaining of multiple devices.

A number of the EL5525 can be stacked for applications requiring more than 18 outputs. The reference inputs can be tied to the rails, enabling each part to output the full voltage range, or alternatively, they can be connected to external resistors to split the output range and enable finer resolutions of the outputs.

The EL5525 has 18 outputs and comes in a 38-pin HTSSOP package. It is specified for operation over the full -40°C to +85°C temperature range.

### Ordering Information

PART NUMBER	PACKAGE	TAPE & REEL	PKG. DWG. #
EL5525IRE	38-Pin HTSSOP	-	MDP0048
EL5525IRE-T7	38-Pin HTSSOP	7"	MDP0048
EL5525IRE-T13	38-Pin HTSSOP	13"	MDP0048
EL5525IREZ (See Note)	38-Pin HTSSOP (Pb-Free)	-	MDP0048
EL5525IREZ-T7 (See Note)	38-Pin HTSSOP (Pb-Free)	7"	MDP0048
EL5525IREZ-T13 (See Note)	38-Pin HTSSOP (Pb-Free)	13"	MDP0048

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

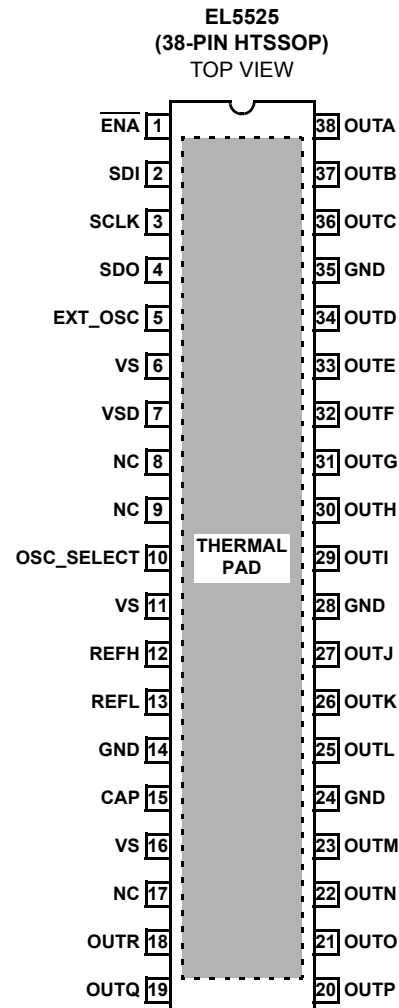

### Features

- 18-channel reference outputs
- Accuracy of  $\pm 0.1\%$
- Supply voltage of 4.5V to 16.5V
- Digital supply 3.3V to 5V
- Low supply current of 15mA
- Rail-to-rail capability
- Internal thermal protection
- Pb-Free plus anneal available (RoHS compliant)

### Applications

- TFT-LCD drive circuits
- Reference voltage generators

### Pinout

**Absolute Maximum Ratings** ( $T_A = 25^\circ\text{C}$ )

Supply Voltage between  $V_S$  and GND . . . . . 4.5V(min) to 18V(max)  
 Supply Voltage between  $V_{SD}$  and GND 3V(min) to  $V_S$  and +7(max)  
 Maximum Continuous Output Current . . . . . 30mA

Ambient Operating Temperature . . . . . -40°C to +85°C  
 Maximum Die Temperature . . . . . 125°C  
 Storage Temperature . . . . . -65°C to +150°C

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

IMPORTANT NOTE: All parameters having Min/Max specifications are guaranteed. Typ values are for information purposes only. Unless otherwise noted, all tests are at the specified temperature and are pulsed tests, therefore:  $T_J = T_C = T_A$

**Electrical Specifications**  $V_S = 15\text{V}$ ,  $V_{SD} = 5\text{V}$ ,  $V_{REFH} = 13\text{V}$ ,  $V_{REFL} = 2\text{V}$ ,  $R_L = 1.5\text{k}\Omega$  and  $C_L = 200\text{pF}$  to 0V,  $T_A = 25^\circ\text{C}$ , unless otherwise specified.

PARAMETER	DESCRIPTION	CONDITIONS	MIN	TYP	MAX	UNIT
<b>SUPPLY</b>						
$I_S$	Supply Current	No load		15	18	mA
$I_{SD}$	Digital Supply Current			0.17	0.35	mA
<b>ANALOG</b>

### General Description

The EL5525 provides a versatile method of providing the reference voltages that are used in setting the transfer characteristics of LCD display panels. The V/T (Voltage/Transmission) curve of the LCD panel requires that a correction is applied to make it linear; however, if the panel is to be used in more than one application, the final curve may differ for different applications. By using the EL5525, the V/T curve can be changed to optimize its characteristics according to the required application of the display product. Each of the eight reference voltage outputs can be set with a 10-bit resolution. These outputs can be driven to within 50mV of the power rails of the EL5525. As all of the output buffers are identical, it is also possible to use the EL5525 for applications other than LCDs where multiple voltage references are required that can be set to 10 bit accuracy.

### Digital Interface

The EL5525 uses a simple 3-wire SPI compliant digital interface to program the outputs. The EL5525 can support the clock rate up to 5MHz.

### Serial Interface

The EL5525 is programmed through a three-wire serial interface. The start and stop conditions are defined by the  $\overline{ENA}$  signal. While the  $\overline{ENA}$  is low, the data on the SDI (serial data input) pin is shifted into the 16-bit shift register on the positive edge of the SCLK (serial clock) signal. The MSB (bit 15) is loaded first and the LSB (bit 0) is loaded last (see Table 1). After the full 16-bit data has been loaded, the  $\overline{ENA}$  is pulled high and the addressed output channel is updated. The SCLK is disabled internally when the  $\overline{ENA}$  is high. The SCLK must be low before the  $\overline{ENA}$  is pulled low.

To facilitate the system designs that use multiple EL5525 chips, a buffered serial output of the shift register (SDO pin) is available. Data appears on the SDO pin at the 16th falling SCLK edge after being applied to the SDI pin.

To control the multiple EL5525 chips from a single three-wire serial port, just connect the  $\overline{ENA}$  pins and the SCLK pins together, connect the SDO pin to the SDI pin on the next

chip. While the  $\overline{ENA}$  is held low, the 16m-bit data is loaded to the SDI input of the first chip. The first 16-bit data will go to the last chip and the last 16-bit data will go to the first chip. While the  $\overline{ENA}$  is held high, all addressed outputs will be updated simultaneously.

The Serial Timing Diagram and parameters table show the timing requirements for three-wire signals.

The serial data has a minimum length of 16 bits, the MSB (most significant bit) is the first bit in the signal. The bits are allocated to the following functions (also refer to the Control Bits Logic Table)

- Bit 15 is always set to a zero
- Bits 14 through 10 select the channel to be written to, these are binary coded with channel A = 0, and channel R = 17
- The 10-bit data is on bits 9 through 0. Some examples of data words are shown in the table of Serial Programming Examples

TABLE 1. CONTROL BITS LOGIC TABLE

BIT	NAME	DESCRIPTION
B15	Test	Always 0
B14	A4	Channel Address
B13	A3	Channel Address

0	1	0	0	0	1	0	0	0	0	0	1	1	1	1	1	1	Channel R, Value = 31

**Analog Section**

**TRANSFER FUNCTION**

The transfer function is:

$$V_{\text{OUT(IDEAL)}} = V_{\text{REFL}} + \frac{\text{data}}{1024} \times (V_{\text{REFH}} - V_{\text{REFL}})$$

where data is the decimal value of the 10-bit data binary input code.

The output voltages from the EL5525 will be derived from the reference voltages present at the V<sub>REFL</sub> and V<sub>REFH</sub> pins. The impedance between those two pins is about 32kΩ.

Care should be taken that the system design holds these two reference voltages within the limits of the power rails of the EL5525. GND < V<sub>REFH</sub> ≤ V<sub>S</sub> and GND ≤ V<sub>REFL</sub> ≤ V<sub>REFH</sub>.

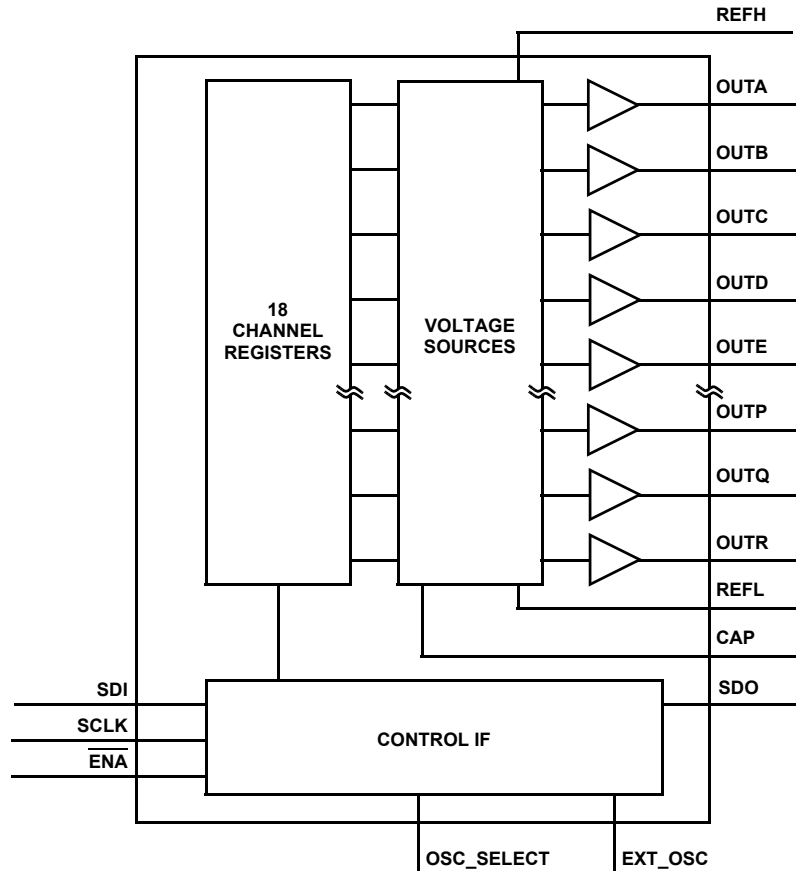

**CLOCK OSCILLATOR**

The EL5525 requires an internal clock or external clock to refresh its outputs. The outputs are refreshed at the falling OSC clock edges. The output refreshed switches open at the rising edges of the OSC clock. The driving load shouldn't be changed at the rising edges of the OSC clock. Otherwise, it will generate a voltage error at the outputs. This clock may be input or output via the clock pin labeled EXT\_OSC. The internal clock is provided by an internal oscillator running at approximately 21kHz and can be output to the EXT\_OSC pin. In a 2 chip system, if the driving loads are stable, one chip may be programmed to use the internal oscillator; then the OSC pin will output the clock from the internal oscillator. The second chip may have the OSC pin connected to this clock source.

For transient load application, the external clock Mode should be used to ensure all functions are synchronized together. The positive edge of the external clock to the OSC pin should be timed to avoid the transient load effect. The Application Drawing shows the LCD H rate signal used, here the positive clock edge is timed to avoid the transient load of the column driver circuits.

After power on, the chip will start with the internal oscillator mode. At this time, the EXT\_OSC pin will be in a high impedance condition to prevent contention. By setting pin 10 to high, the chip is on external clock mode. Setting pin 10 to low, the chip is on internal clock mode.

## Block Diagram

### CHANNEL OUTPUTS

Each of the channel outputs has a rail-to-rail buffer. This enables all channels to have the capability to drive to within 50mV of the power rails, (see Electrical Characteristics for details).

When driving large capacitive loads, a series resistor should be placed in series with the output. (Usually between 5Ω and 50Ω).

Each of the channels is updated on a continuous cycle, the time for the new data to appear at a specific output will depend on the exact timing relationship of the incoming data to this cycle.

The best-case scenario is when the data has just been captured and then passed on to the output stage immediately; this can be as short as 48μs. In the worst-case scenario, this will be 860μs for EL5525, when the data has just missed the cycle at  $f_{OSC} = 21\text{kHz}$ .

When a large change in output voltage is required, the change will occur in 2V steps, thus the requisite number of timing cycles will be added to the overall update time. This means that a large change of 16V can take between 6.8ms and 7.2ms depending on the absolute timing relative to the update cycle.

### Output Stage and the Use of External Oscillator

Simplified output sample and hold amp stage for one channel

FIGURE 7.

The output voltage is generated from the DAC, which is  $V_{IN}$  in the above circuit. The refreshed switches are controlled by the internal or external oscillator signal. When the OSC clock signal is low, switches  $S_1$  and  $S_2$  are closed. The output  $V_{OUT} = V_{IN}$  and at the same time the sample and hold cap CH is being charged. When the OSC clock signal is high, the refreshed switches  $S_1$  and  $S_2$  are opened and the output voltage is maintained by CH. This refreshed process will repeat every 18 clock cycles for each channel. The time takes to update the output depends on the timing at the  $V_{IN}$

and the state of the switches. It can take 1 to 18 clock cycles to update each output.

For the sample and hold capacitor CH to maintain the correct output voltage, the driving load shouldn't be changed at the rising edge of the OSC signal. Since at the rising edge of the OSC clock, the refreshed switches are being opened, if the load changes at that time, it will generate an error output voltage. For a fixed load condition, the internal oscillator can be used.

For the transient load condition, the external OSC mode should be used to avoid the conflict between the rising edge of the OSC signal and the changing load. So a timing delay circuit will be needed to delay the OSC signal and avoid the rising edge of the OSC signal and changing the load at the same time.

**TRANSIENT LOAD RESPONSE**

FIGURE 8.

Channel 3 --- sinking and sourcing 5mA current

Channel 2 --- EXT\_OSC signal

Channel 1 --- V<sub>OUT</sub>

Here, the OSC signal is synchronized to the load signal. The rising edge of the OSC signal is then delayed by some amount of time and gives enough time for CH to be charged to a new voltage before the switches are opened.

**CHANNEL TO CHANNEL REFRESH**

FIGURE 9.

Ch1 --- Output1

Ch3 --- Output2

Ch2 --- EXT\_OSC

At the falling edge of the OSC, output 1 is being refreshed and one clock cycle later, output 2 is being refreshed. The spike you see here is the response of the output amplifier when the refreshed switches are closed. When driving a big capacitor load, there will be ringing at the spikes because the phase margin of the amplifier is decreased.

The speed of the external OSC signal shouldn't be greater than 70kHz because for the worst condition, it will take at least 4µs to charge the sample and hold capacitor CH. The pulse width has to be at least 4µs long. From our lab test, the duty cycle of the OSC signal must be greater than 30%.

**POWER DISSIPATION**

With the 30mA maximum continues output drive capability for each channel, it is possible to exceed the 125°C absolute maximum junction temperature. Therefore, it is important to calculate the maximum junction temperature for the application to determine if load conditions need to be modified for the part to remain in the safe operation.

The maximum power dissipation allowed in a package is determined according to:

$$P_{D\text{MAX}} = \frac{T_{J\text{MAX}} - T_{A\text{MAX}}}{\theta_{JA}}$$

where:

- T<sub>JMAX</sub> = Maximum junction temperature
- T<sub>AMAX</sub> = Maximum ambient temperature
- θ<sub>JA</sub> = Thermal resistance of the package
- P<sub>DMAX</sub> = Maximum power dissipation in the package

The maximum power dissipation actually produced by the IC is the total quiescent supply current times the total power supply voltage and plus the power in the IC due to the loads.

$$P_{D_{MAX}} = V_S \times I_S + \sum[(V_S - V_{OUTi}) \times I_{LOADi}]$$

when sourcing, and:

$$P_{D_{MAX}} = V_S \times I_S + \sum(V_{OUTi} \times I_{LOADi})$$

when sinking.

Where:

- $i = 18$
- $V_S$  = Supply voltage
- $I_S$  = Quiescent current
- $V_{OUTi}$  = Output voltage of the  $i$  channel
- $I_{LOADi}$  = Load current of the  $i$  channel

By setting the two  $P_{D_{MAX}}$  equations equal to each other, we can solve for the  $R_{LOADs}$  to avoid the device overheat. The package power dissipation curves provide a convenient way to see if the device will overheat.

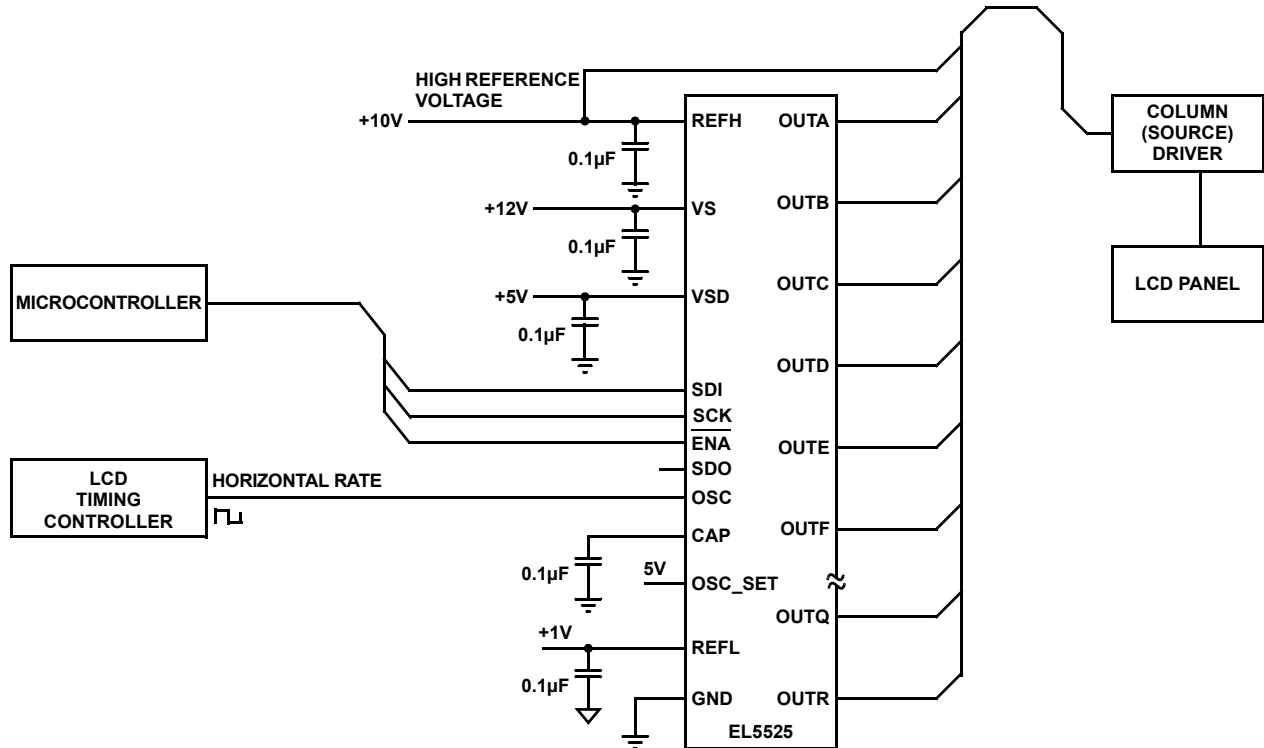

**THERMAL SHUTDOWN**

The EL5525 has an internal thermal shutdown circuitry that prevents overheating of the part. When the junction temperature goes up to about 150°C, the part will be disabled. When the junction temperature drops down to about 120°C, the part will be enabled. With this feature, any short circuit at the outputs will enable the thermal shutdown circuitry to disable the part.

**POWER SUPPLY BYPASSING AND PRINTED CIRCUIT BOARD LAYOUT**

Good printed circuit board layout is necessary for optimum performance. A low impedance and clean analog ground plane should be used for the EL5525. The traces from the two ground pins to the ground plane must be very short. The thermal pad of the EL5525 should be connected to the analog ground plane. Lead length should be as short as possible and all power supply pins must be well bypassed. A 0.1µF ceramic capacitor must be placed very close to the  $V_S$ ,  $V_{REFH}$ ,  $V_{REFL}$ , and CAP pins. A 4.7µF local bypass tantalum capacitor should be placed to the  $V_S$ ,  $V_{REFH}$ , and  $V_{REFL}$  pins.

**Application Drawing**

HTSSOP Package Outline Drawing

- Notes:
- Dimension "D" does not include mold flash, protrusions or gate burrs. Mold flash, protrusions or gate burrs shall not exceed 0.15 per side.
  - Dimension "E1" does not include interlead flash or protrusion. Interlead flash or protrusion shall not exceed 0.25 per side.
  - Dimensions "D" and "E1" are measured at datum plane H.
  - Dimensioning and tolerancing per ASME Y14.5M-1994.
