PRODUCTION DATA SHEET

KEY FEATURES

- Internal Reference 1.17V ±2% Accuracy (Line and Temperature)
- 4V to 6.0V Input Range
- Adj. Output From 1.17V to V_{IN}
- Output Current (I_{DC} >850mA)
- Quiescent Current < 300µA</p>
- 1MHz Operation Frequency
- MSOP 8-Pin

APPLICATIONS/BENEFITS

- Portable Microprocessor Core Voltage Supplies
- 5V to 3V

IMPORTANT: For the most current data, consult MICROSEMI's website: http://www.microsemi.com

mode

DESCRIPTION

PRODUCT HIGHLIGHT

The LX1910 does not require a

minimum load current for stable

operation. There is no Under Voltage

Lockout for the input voltage,

operational range includes 4V to 6V.

The regulator is capable of providing

an output dc load current of 850mA.

The SHDN pin places the device in a

sleep-mode drawing less than 1uA of

The LX1910 comes in space-saving

MSOP package allowing a complete

application circuit to occupy a very

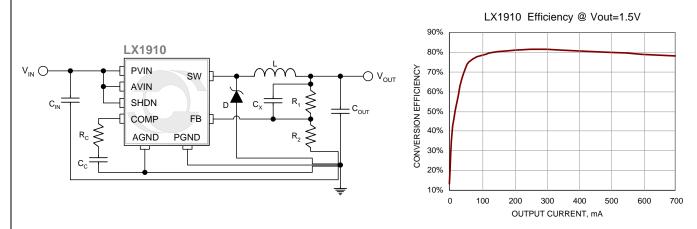

small PCB area. These features make

the LX1910 ideal for use in

SmartPhones, PDAs, or other battery-

quiescent current.

operated devices

PACKAGE ORDER INFO

APPLICATION NOTE

FUNCTIONAL DESCRIPTION

The LX1910 implements a PFM / PWM architecture that improves power management efficiency across the output load range.

OUTPUT VOLTAGE PROGRAMMING

Resistors R1 and R2 program the output voltage. An optional capacitor C_X may be inserted across R1 to improve the transient response (see Figure 1). The value of R2 should be less than 100K Ω . The value of R1 can be determined using the following equation, note V_{REF} is also referred to as V_{FBT} .

$$R1 = R2 \left[\left(\frac{V_{OUT}}{V_{REF}} \right) - 1 \right]$$

DESIGN EXAMPLE:

Let R2 equal 50K and the required V_{OUT} equal to 3.0V.

$$R1 = 50K \left[\left(\frac{3V}{1.17} \right) - 1 \right] = 78K\Omega$$

DIODE SELECTION

A Schottky diode is recommended for use with the LX1910 because it provides fast switching and superior reverse recovery performance. The *Microsemi* UPS5817 (20V @ 1A) makes an effective choice for most applications.

INDUCTOR SELECTION

Selecting the appropriate inductor type and value ensures optimal performance of the converter circuit for the intended application. This selection process requires the designer to make trade-offs between circuit performance and cost. A primary consideration requires the selection of an inductor that will not saturate at the peak current level. Other considerations that affect inductor choice include EMI, output voltage ripple, and overall circuit efficiency. The inductor that works best depends upon the application's requirements. Further, some experimentation with actual devices in-circuit is typically necessary to make the most effective choice.

The LX1910 allows for a broad selection of inductor values and choosing a value between 2.2μ H and 30μ H supports a majority of applications. Selecting a larger inductor value can increase efficiency and reduce output voltage ripple. Smaller inductors typically provide smaller package size (critical in many portable applications) at the expense of increasing output ripple current. Regardless of inductor value, selecting a device manufactured with a ferrite-core produces lower losses at higher switching frequencies and thus better overall performance.

CAPACITOR SELECTION

To minimize ripple voltage, output capacitors with a low series resistance (ESR) are recommended. Multi-layer ceramic capacitors with X5R or X7R dielectric make an effective choice because they feature small size, very low ESR, a temperature stable dielectric, and can be connected in parallel to increase capacitance. Typical capacitance values of 4.7 to 30µF have proven effective. Other low ESR capacitors such as solid tantalum, specialty polymer, or organic semiconductor, make effective choices provided that the capacitor is properly rated for the output voltage and ripple current. Finally, choose an input capacitor of sufficient size to effectively decouple the input voltage source impedance (e.g., $C_{IN} \ge 4.7 \mu F$).

LAYOUT CONSIDERATIONS

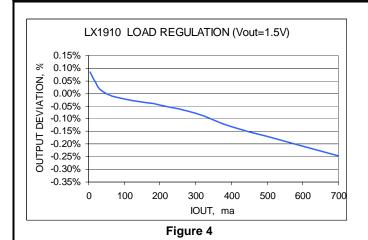

The high peak currents and switching frequencies present in DC/DC converter applications require careful attention to device layout for optimal performance. Basic design rules include: (1) maintaining wide traces for power components (e.g., width > 50mils); (2) place C_{IN} , C_{OUT} , the Schottky diode, and the inductor close to the LX1910; (3) minimizing trace capacitance by reducing the etch area connecting the SW pin to the inductor; and (4) minimizing the etch length to the FB pin to reduce noise coupling into this high impedance sense input. Other considerations include placing a 0.1uF capacitor between the LX1910 V_{OUT} pin and GND pin to reduce high frequency noise and decoupling the V_{IN} pin using a 0.1µF capacitor.
