

Motor Driver IC Series for Printers

Three-phase Brushless

Motor pre-driver for Paper Feed Use

BA6680FS, BD6761FS, BD6762FV

●Description

This product is a motor predriver for high-side/low-side N-channel MOS-FET with a built-in boost (step-up) driver. BA6680FS and BD6761FS are controlled by the external servo signal. The BD6762FV incorporates a servo circuit (Speed discriminator + PLL servo).

●Features

- 1) Predriver for high-side/low-side N-channel MOS-FET
- 2) Built-in boost (step-up) circuit
- 3) Built-in FG and hysteresis amplifiers
- 4) Built-in current limit circuit
- 5) Built-in thermal shutdown circuit
- 6) Built-in forward/reverse rotation switching circuit (BD6761FS, BD6762FV)
- 7) Built-in short brake circuit (BD6761FS, BD6762FV)
- 8) Built-in low voltage protection circuit (BD6761FS, BD6762FV)
- 9) Built-in speed lock detection circuit (BD6762FV)
- 10) Built-in motor lock protection circuit (BD6762FV)
- 11) Built-in start-stop circuit (BD6762FV)
- 12) Built-in servo circuit (Speed discriminator + PLL) (BD6762FV)
- 13) Built-in frequency multiplication circuit (BD6762FV)
- 14) 120°, direct PWM drive (BA6680FS)
- 15) 180°, direct PWM drive (BD6761FS)
- 16) 120°, slope switchable direct PWM drive (BD6762FV)

●Applications

Main paper feed motor for laser printer and PPC

●Absolute maximum ratings (Ta=25°C)

Parameter	Symbol	Limit			Unit
		BA6680FS	BD6761FS	BD6762FV	
Applied voltage	VCC	36	36	36	V
Applied voltage	VG	36	36	36	V
Pin input voltage	Vin	VREG	VREG	VREG	V
Power dissipation	Pd	950 ^(※1)	950 ^(※1)	1100 ^(※2)	mW
Operating temperature range	TOPR	-25~+75	-35~+75	-25~+75	°C
Storage temperature range	TSTG	-40~+150	-40~+150	-40~+150	°C
Junction temperature	Tjmax	150	150	150	°C

※1 Reduced by 7.6 mW/°C over 25°C, when mounted on a glass epoxy board (70 mm × 70 mm × 1.6 mm).

※2 Reduced by 8.8 mW/°C over 25°C, when mounted on a glass epoxy board (70 mm × 70 mm × 1.6 mm).

●Product lineup

	BA6680FS	BD6761FS	BD6762FV	Unit
Power supply voltage (VCC)	16~28	16~28	16~28	V
Drive type	120°	180°	120° / 120° slope	—
Servo	No	No	Yes	—

● **Electrical Characteristics**

BA6680FS (Unless otherwise specified, Ta=25°C, VCC=25.5V)

Parameter	Symbol	Limit			Unit	Conditions
		Min.	Typ.	Max.

● IC Operation

1) Hall input and output

The hall amplifier shapes the hall input signal to generate the drive signal.

This drive signal is amplified in the predriver block and the gate voltage is output for N-channel MOS FET.

2) PWM operation

PWM oscillating frequency is determined by the triangular waveform frequency which is set by the external constant.

This triangular waveform voltage and the listed voltage in the following chart are compared to perform PWM drive.

	Rfe, RFE	Cfe, CFE	Cfe, CFE pin charge/discharge current I	Frequency (Typ.)	Comparison voltage
BA6680FS	50k Ω	100pF	0.4V/R	15.5kHz	Pref
BD6761FS	50k Ω	1000pF	1.6V/R	16.5kHz	Drive signal shaped by the hall amplifier
BD6762FV	20k Ω	1000pF	VRFE/R	16kHz	Integration amplifier output pin voltage

3) Boost circuit (step-up circuit) (common)

BA6680FS generates the triangular waveform by connecting a capacitor (COSC = 100pF: Frequency = 95 kHz) between the OSC and GND pins. BD6761FS (Frequency = 62.5 kHz) and BD6762FV (Frequency = 125 kHz) generate the triangular waveform by the internal free-run oscillator and the rectangular waveform at CP1. When a capacitor is connected between CP1 and CP2, and VG and GND, the step-up voltage is generated at VG pin. In this case, set VCC so that VG does not exceed the absolute maximum ratings (36 V).

	Triangular waveform oscillating frequency	Charge pump voltage (VG pin voltage)
BA6680FS	95kHz(COSC=100pF)	VCC+7V
BD6761FS	62.5 kHz	VCC+6V
BD6762FV	125 kHz	VCC+6.7V

4) FG amplifier (common)

Set the FG amplifier gain so that the FGOUT pin is within the range of high and low output voltage and the amplitude is higher than the hysteresis width (250 mV: max) of the HYS amplifier.

FGSOUT pin is an open collector which requires a resistor to the supply line. Voltage higher than 36 V must not be applied to the FGSOUT pin.

5) ACC, DEC circuits (BA6680FS, BD6761FS)

When a resistor is connected to the RCP pin and the low voltage is input to the ACC pin, the current flows out from the CPOUT pin. When the low signal is input to the DEC pin, the current flows in to the CPOUT pin. Furthermore, when the ACC pin and DEC pin both set to low, the current flows in to the CPOUT pin. This current can be converted to the voltage by connecting a filter between the CPOUT and GND pins.

The voltage generated at the CPOUT pin controls the PWM's on-duty and maintains the constant motor rotation by inputting the controlled signal to ACC and DEC pins.

6) Current limit operation

The CL voltage (BA6680FS, BD6761FS) and RF voltage (BD6762FV) become the current limit voltage and the current limit circuit limits PWM on_dutty. It also turns off the current limit circuit (current limit clear) at the peak of PWM triangular waveform and makes the current flow again. Output current Iomax at this time are shown in the table.

	Current limit current
BA6680FS	Iomax=0.38/RNF [A]
BA6761FS	Iomax=0.48/RNF [A]
BA6762FV	Iomax=0.26/RNF [A]

7) Preventing low-side and high-side switch overlapping (BD6761FS, BD6762FV)

When the low-side gate voltage becomes high while the high-side gate voltage is low, or vice versa, a prevention delay time is provided with t=3.2 μs (TYP value). When the input capacity of external FET is C and the gate connection resistor is R, set R to satisfy the following equation:

$$C \leq \frac{1.8 \mu}{10 \times (24 + R)}$$

Note: Confirm by testing on the actual system.

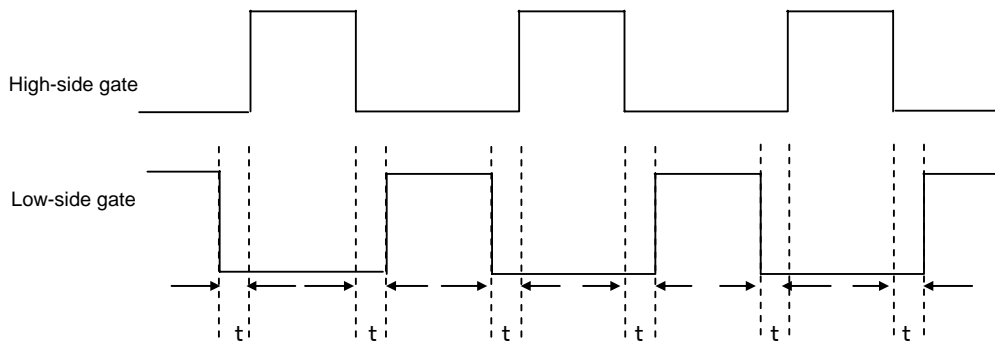

Fig.18 High/Low-side Simultaneous On Prevention Timing Chart

8) Short brake (BD6761FS and BD6762FV)

BD6761FS operates the short brake action with the ACC and DEC pins set to low, while BD6762FV does so with the SB pin set to OPEN or high. At the time of short brake, the high-side gate is turned off and the low-side is turned on. At the time of short brake operating, the current flows to the output FET, which is set by the motor's counter electromotive voltage and coil impedance. Since this current does not flow through the overcurrent protection (current limit) detection resistor, the overcurrent protection does not operate as the IC operates. Therefore, the current must not exceed the output FET rating.

9) Forward/reverse rotation circuit (BD6761FS and BD6762FV)

Forward /reverse rotation of motor can be switched according to the FR pin input conditions. Logics of the hall input and output conditions according to the FR pin input conditions are shown in the I/O conditions table (P.12/24). If the FR pin is switched during the motor rotation, when the prevention circuit in the IC operates, the feed through current does not flow. However, since the motor current flows toward the power source due to the electromotive force, the voltage may be raised if the power source does not have the power supply voltage absorption ability. Examine the capacitor characteristics between the power supply and ground sufficiently. Power supply voltage and step-up voltage must not exceed the absolute maximum ratings. When the physical measures are taken, such as increasing the capacitor value which is connected between the power supply and ground, characteristics must be monitored prior to use.

10) Start/stop circuit (BD6762FV)

When the ST/SP pin is in the state of OPEN or high, IC is on standby. In standby mode, some circuit operations are turned off to reduce the current consumption.

When the ST/SP pin is in the state of low, the IC operates.

11) Low voltage protection circuit (BD6761FS and BD6762FV)

An IC with a built-in low voltage protection circuit. When VCC becomes lower than 11.5 V (Typ.), the high-side and low-side gates are both turned off and turn the coil off. Protection off voltage is 12.0 V (Typ.) and hysteresis width is 0.5 V (Typ.).

Since the motor locking protection detection circuit operates in BD6762FV during the low voltage protection operation, if the low voltage protection operating time becomes longer than the motor locking protection detection time, the operation moves to the motor locking protection operation after the low voltage protection operation.

12) Built-in 120° slope PWM logic (BD6762FV)

It is possible to perform 120° drive by setting 120/SL pin to OPEN or making high. 120° slope drive is possible by setting the 120/SL pin to OPEN or making high. Low noise design is realized by reducing the electromagnetic sound generated at the time of phase switching by means of gradually changing the output PWM on-duty during 120° slope energization. However, at the time of startup or the hall input frequency is lower than about 3 Hz (Typ. value), it becomes 120° drive. When the hall input frequency is more than about 3 Hz (Typ. value) and the rise of hall U-phase is detected 7 times, it switches to the 120° slope drive.

13) Servo circuit (BD6762FV)

- Frequency multiplication circuit (Dividing period) (BD6762FV)

An IC with a built-in the frequency multiplication circuit.

Servo circuit is composed of the feedback loop as shown in the diagram and flows in/out the current ($22\ \mu\text{A}$: Typ.) to the LPF pin (30 pin) by detecting the phase difference between the CLKIN pin (29 pin) and the frequency dividing unit output FCOMP. The phase difference signal output to the LPF pin (30 pin) is smoothed by the filter which is connected at the IC external of the LPF pin (30 pin) and this voltage is input to the VCO (Voltage control oscillation circuit) to determine the frequency for the internal signal FVCO. Since the dividing ratio of this frequency dividing unit is set to 1024, the relation of:

$$FVCO[\text{Hz}] = 1024 \cdot FCOMP[\text{Hz}] ,$$

can be obtained. The FCOMP and CLKIN have the same frequency according to the feedback loop as shown in the following diagram. Therefore the multiplied frequency of 1024 times of FCOMP or CLKIN is acquired as the FVCO frequency.

- Speed discriminator (BD6762FV)

The FGSOUT signal (28 pin), which detects the motor rotation speed and the reference clock in the IC, are compared and the acceleration/deceleration signal is output to the DOUT pin (32 pin). Reference clock is the signal (FVCO) that the CLKIN signal (29 pin) is multiplied by 1024. When the FG period is short to the reference clock period, it is determined that the motor revolution speed is too fast and the difference from the reference clock period is output to the DOUT pin as the deceleration command. When the FG period is long, the difference is output as an accelerating command.

- PLL (BD6762FV)

Phases of the FGSOUT (28 pin) signal, which detected the motor revolution speed and the CLKIN (29 pin) input from the external are compared, and if the FG phase leads to CLKIN (28 pin), the difference is output as the deceleration command. If the FG phase lags, the difference is output as the acceleration command.

- Integration amplifier (BD6762FV)

Speed error of the reference clock, which is obtained in the speed discriminator block and the FG signal, and the phase difference signal of the CLKIN acquired in PLL block and the FG are integrated together and smoothed to become the DC voltage. This smoothed signal determines the PWM on-duty.

14) Speed lock detection circuit (BD6762FV)

When the motor speed is within $\pm 6.25\%$ range to the CLKIN signal (29 pin), L is output to the LD pin (36 pin) output.

Since the LD pin (36 pin) has the open/drain output format, use as it is pulled up to the power supply with the resistor ($100\text{k}\Omega$). At this time, pay attention so that the voltage more than 36 V is not applied to the LD pin.

15) Motor locking protection (BD6762FV)

The motor locking protection circuit determines when the motor is in the locking condition. When the motor speed is not in the lock range (preset value: $\pm 6.25\%$) and the motor locking detection time T_{LP} elapsed, the high-side and low-side output gates are both turned off.

Motor locking protection can be cleared by making the condition Low, after setting the ST/SP pin or the SB pin to OPEN or making high. Motor locking detection time T_{LP} is determined by the capacitor C7 which is connected to the LP pin and the count number CLP (preset value: 96) of the internal counter.

$$T_{LP} = 2 \times 10^5 \times C7 \times CLP \quad [\text{S}]$$

●Selecting application components

Design method	Design example
①Output FET This IC is the predriver for high-side and low-side N-channel MOS FET drive. Select the FET with the required current capacity to drive the motor.	Recommended FET RDS035L03 (A)
②Diodes (BD67861FS) Diodes are required to protect between the gate and source of output FET.	Recommended diode 1SS355 Insert the diode in the direction from high-side FET source to the gate side (in the forward direction).
③Protection capacitor between the output FET drain and source Check the operation so that the voltage between the output FET drain and source does not exceed the absolute maximum ratings due to the fluctuation of VCC at the time of PWM driving and then set the value.	A value of 0.01 μ F to 0.1 μ F is recommended. A value of 0.1 μ F is appropriate for the capacitance. Insert the capacitor between the output FET drain and source. (Position at the close point to FET as much as possible.)
④VB current capacitance capacitor Current capacity from VG changes according to the capacitance to be connected. However, if the capacitance is too large, the following action is delayed when VCC starts up, and the magnitude relation becomes VCC > VG. Typically, should be VCC < VG and the large current may flow in internal block circuits and result in damaging the circuits. When VG is directly supplied from the external block without using the internal circuits, disconnect the capacitor between CP1 and CP2, and connect the 20k Ω resistor (for noise reduction) between CP1 and ground to use.	A value of 0.01 μ F is appropriate for the capacitor between CP1 and CP2 (A value of 0.01 μ F 0.1 μ F is recommended.) A value of 0.1 μ F is appropriate for the capacitor between VG and VCC.
⑤PWM frequency PWM frequency can be adjusted by the capacitance and resistance to connect. When the frequency is high, the heat generation increases due to switching loss. When the frequency is low, it enters audible range. Check the operation with the actual product and determine the constant.	The following constants are appropriate: BA6680FS Cfe=100pF, Rfe=50k Ω , fo=15.5kHz(TYP.) BD6761FS Cfe=1000pF, Rfe=50k Ω , fo=16.5kHz(TYP.) BD6762FV Cfe=1000pF, Rfe=20k Ω , fo=16.0kHz(TYP.)
⑥Hall input level The current value to feed to the hall element changes by changing the resistance and the amplitude level of hall element. Amplitude level increases when the resistance value is chosen smaller by considering the noise affect. Pay attention to the hall input voltage range. BA6680FS (1.0V to 4.9V), BD6761FS (1.5V to 4.1V) and BD6762FV (0V to 3V)	Connect to the transistor base via 1k Ω resistor (base current limit) from the VREG pin. Connect the transistor collector to VCC, the emitter to the hall element via R1. Connect the ground side of hall element to the ground via R2. A value of 200 Ω to 1k Ω is recommended. A value of 200 Ω is appropriate. When connecting to the VCC side directly with R1, values of R1=5k Ω and R2=2k Ω are appropriate.
⑦VREG VREG which is the internal voltage output pin drives the circuits in IC. Connect the capacitor to stabilize it.	A value of 0.01 μ F to 0.1 μ F is recommended. A value of 0.1 μ F is appropriate.
⑧Current limit The current flowing to FET can be controlled by setting the resistance value. Determine the constant according to the motor specifications.	Following equation shows the current value: BA6680FS $I_{max}=0.38/RNF$ [A] BD6761FS $I_{max}=0.48/RNF$ [A] BD6762FV $I_{max}=0.26/RNF$ [A]
⑨OSC frequency (BA6680FS) Triangular waveform is formed by the capacitance to connect.	A value of C=100pF and Frequency=95kHz (Typ.) is appropriate.
⑩Hall input noise Insert capacitors between the hall phases in order to eliminate the hall input noise due to the effect by the pattern routing design.	A value of 0.01 μ F is appropriate for the capacitor to be installed between the hall phases. A value of 0.01 μ F to 0.1 μ F is recommended.
⑪CL (RF) voltage smoothing low pass filter Smooth the CL (RF) voltage which has PWM noise through the low pass filter.	A value of C = 470pF and R=1k Ω is appropriate for the low pass filter. For the external constant, since the impedance is high, make sure to design the pattern with the shortest circuit route so that the circuit is hard to be affected by noise.
⑫FG AMP constant setting FG AMP gain: GFG is the ratio of R1 and R2 calculated by the following equation: $GFG=20\log R2/R1$ [dB] Set up the gain so that the FGOUT amplitude is large enough to the hysteresis level of the hysteresis comparator and it cannot be clamped by the high and low output voltages (VFGOH and VFGOL).	R1 and C1 form a high pass filter and R2 and C2 form a low pass filter. Each cut off frequency; f_{MPF} and f_{LPF} is determined by the following equation: $f_{MPF}=1/2 \pi R1C1$, $f_{LPF}=1/2 \pi R2C2$ Set the value so that the main signal from PG by the motor is not attenuated but the unnecessary noise.

<p>⑳ LPF external constant (BD6762FV)</p> <p>Filter composed of C8, C9 and R7 smoothes the current pulses output from the LPF pin and converts it to DC.</p> <p>This impedance Z is shown by the following equation:</p> $Z = R7 \times \frac{C9}{C8+C9} \times \frac{S+\omega_2}{S \left(1 + \frac{S}{\omega_1} \right)}$ <p>When the pole frequency is set to fP1 and fP2, they are:</p> <p>fP1 = $\omega_1/2\pi = 1/2\pi (C8/C9)R7$ fP2 = $\omega_2/2\pi = 1/2\pi C9R7$</p>	<p>Recommended values:</p> <p>C8: 0.1 μF to 0.6 μF; a value of 0.33 μF is appropriate.</p> <p>C9: 0.1 μF to 0.6 μF; a value of 0.33 μF is appropriate.</p> <p>R7: 0.5kΩ to 10kΩ; a value of 2kΩ is appropriate.</p>

※Setting values in these materials are only for reference. Actual set may change its characteristics due to the board layout, wiring and components each type uses. Please perform the sufficient verification using the actual product for the field operation.

● Operation Notes

1. Absolute maximum ratings

An excess in the absolute maximum ratings, such as supply voltage, temperature range of operating conditions, etc., can break down the devices, thus making impossible to identify breaking mode, such as a short circuit or an open circuit. If any over rated values will expect to exceed the absolute maximum ratings, consider adding circuit protection devices, such as fuses.

2. Connecting the power supply connector backward

Connecting of the power supply in reverse polarity can damage IC. Take precautions when connecting the power supply lines.
An external direction diode can be added.

3. Power supply lines

Design PCB layout pattern to provide low impedance GND and supply lines. To obtain a low noise ground and supply line, separate the ground section and supply lines of the digital and analog blocks. Furthermore, for all power supply terminals to ICs, connect a capacitor between the power supply and the GND terminal. When applying electrolytic capacitors in the circuit, note that capacitance characteristic values are reduced at low temperatures.

4. GND voltage

The potential of GND pin must be minimum potential in all operating conditions.

5. Thermal design

Use a thermal design that allows for a sufficient margin in light of the power dissipation (Pd) in actual operating conditions.

6. Inter-pin shorts and mounting errors

Use caution when positioning the IC for mounting on printed circuit boards. The IC may be damaged if there is any connection error or if pins are shorted together.

7. Operation in a strong electromagnetic field

Use caution when using the IC in the presence of a strong electromagnetic field as doing so may cause the IC to malfunction.

8. ASO

When using the IC, set the output transistor so that it does not exceed absolute maximum ratings or ASO.

9. Thermal shutdown circuit

The IC incorporates a built-in thermal shutdown circuit (TSD circuit). The thermal shutdown circuit (TSD circuit) is designed only to shut the IC off to prevent thermal runaway. It is not designed to protect the IC or guarantee its operation. Do not continue to use the IC after operating this circuit or use the IC in an environment where the operation of this circuit is assumed.

	TSD on temperature [°C] (Typ.)	Hysteresis temperature [°C] (Typ.)
BA6680FS	175	25
BD6761FS	175	35
BD6762FV	175	23

10. PWM drive

Voltage between the output FET drain and source may exceed the absolute maximum ratings due to the fluctuation of VCC at the time of PWM driving. If there is the threat of this problem, it is recommended to take physical countermeasures for safety such as inserting the capacitor between the VCC pin of FET and the detection resistor pin.

11. Testing on application boards

When testing the IC on an application board, connecting a capacitor to a pin with low impedance subjects the IC to stress. Always discharge capacitors after each process or step. Always turn the IC's power supply off before connecting it to or removing it from a jig or fixture during the inspection process. Ground the IC during assembly steps as an antistatic measure. Use similar precaution when transporting or storing the IC.

12. Regarding input pin of the IC

This monolithic IC contains P+ isolation and P substrate layers between adjacent elements in order to keep them isolated.

P-N junctions are formed at the intersection of these P layers with the N layers of other elements, creating a parasitic diode or transistor. For example, the relation between each potential is as follows:

When $GND > Pin A$ and $GND > Pin B$, the P-N junction operates as a parasitic diode.

When $GND > Pin B$, the P-N junction operates as a parasitic transistor.

Parasitic diodes can occur inevitable in the structure of the IC. The operation of parasitic diodes can result in mutual interference among circuits, operational faults, or physical damage. Accordingly, methods by which parasitic diodes operate, such as applying a voltage that is lower than the GND (P substrate) voltage to an input pin, should not be used.

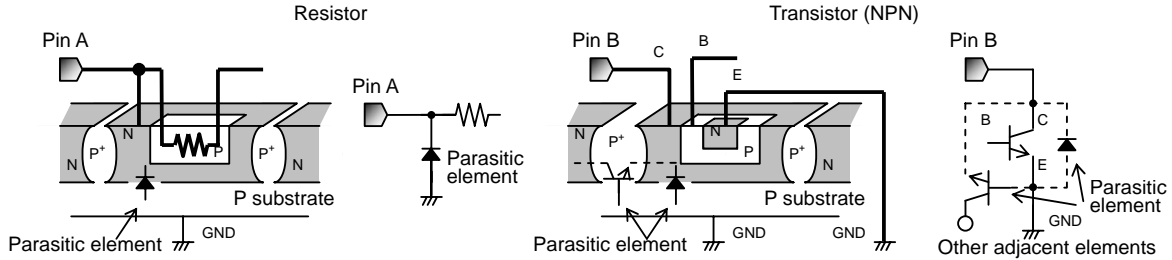

Fig.31 Example of IC structure

13. Ground Wiring Pattern

When using both small signal and large current GND patterns, it is recommended to isolate the two ground patterns, placing a single ground point at the ground potential of application so that the pattern wiring resistance and voltage variations caused by large currents do not cause variations in the small signal ground voltage. Be careful not to change the GND wiring pattern of any external components, either.

SSOP-B40

- The contents described herein are correct as of October, 2005
- The contents described herein are subject to change without notice. For updates of the latest information, please contact and confirm with ROHM CO.,LTD.
- Any part of this application note must not be duplicated or copied without our permission.
- Application circuit diagrams and circuit constants contained herein are shown as examples of standard use and operation. Please pay careful attention to the peripheral conditions when designing circuits and deciding upon circuit constants in the set.
- Any data, including, but not limited to application circuit diagrams and information, described herein are intended only as illustrations of such devices and not as the specifications for such devices. ROHM CO.,LTD. disclaims any warranty that any use of such devices shall be free from infringement of any third party's intellectual property rights or other proprietary rights, and further, assumes no liability of whatsoever nature in the event of any such infringement, or arising from or connected with or related to the use of such devices.
- Upon the sale of any such devices, other than for buyer's right to use such devices itself, resell or otherwise dispose of the same, implied right or license to practice or commercially exploit any intellectual property rights or other proprietary rights owned or controlled by ROHM CO., LTD. is granted to any such buyer.
- The products described herein utilize silicon as the main material.
- The products described herein are not designed to be X ray proof.

The products listed in this catalog are designed to be used with ordinary electronic equipment or devices (such as audio visual equipment, office-automation equipment, communications devices, electrical appliances and electronic toys). Should you intend to use these products with equipment or devices which require an extremely high level of reliability and the malfunction of which would directly endanger human life (such as medical instruments, transportation equipment, aerospace machinery, nuclear-reactor controllers, fuel controllers and other safety devices), please be sure to consult with our sales representative in advance.

- The contents described herein are subject to change without notice. The specifications for the product described in this document are for reference only. Upon actual use, therefore, please request that specifications to be separately delivered.
- Application circuit diagrams and circuit constants contained herein are shown as examples of standard use and operation. Please pay careful attention to the peripheral conditions when designing circuits and deciding upon circuit constants in the set.
- Any data, including, but not limited to application circuit diagrams information, described herein are intended only as illustrations of such devices and not as the specifications for such devices. ROHM CO.,LTD. disclaims any warranty that any use of such devices shall be free from infringement of any third party's intellectual property rights or other proprietary rights, and further, assumes no liability of whatsoever nature in the event of any such infringement, or arising from or connected with or related to the use of such devices.
- Upon the sale of any such devices, other than for buyer's right to use such devices itself, resell or otherwise dispose of the same, no express or implied right or license to practice or commercially exploit any intellectual property rights or other proprietary rights owned or controlled by
- ROHM CO., LTD. is granted to any such buyer.
- Products listed in this document are no antiradiation design.

The products listed in this document are designed to be used with ordinary electronic equipment or devices (such as audio visual equipment, office-automation equipment, communications devices, electrical appliances and electronic toys).

Should you intend to use these products with equipment or devices which require an extremely high level of reliability and the malfunction of which would directly endanger human life (such as medical instruments, transportation equipment, aerospace machinery, nuclear-reactor controllers, fuel controllers and other safety devices), please be sure to consult with our sales representative in advance.

It is our top priority to supply products with the utmost quality and reliability. However, there is always a chance of failure due to unexpected factors. Therefore, please take into account the derating characteristics and allow for sufficient safety features, such as extra margin, anti-flammability, and fail-safe measures when designing in order to prevent possible accidents that may result in bodily harm or fire caused by component failure. ROHM cannot be held responsible for any damages arising from the use of the products under conditions out of the range of the specifications or due to non-compliance with the NOTES specified in this catalog.

Thank you for your accessing to ROHM product informations.
