#### 32-Bit RISC Microprocessor TX19 Family TMP1942CYUE/CZUE/CZXBG

#### 1. Outline and Features

The TX19 is a family of high-performance 32-bit microprocessors that offers the speed of a 32-bit RISC solution with the added advantage of a significantly reduce code size of a 16-bit architecture. The instruction set of the TX19 includes as a subset the 32-bit instructions of the TX39, which is based on the MIPS  $R3000A^{TM}$  architecture. Additionally, the TX19 supports the MIPS16<sup>TM</sup> Application-Specific Extensions (ASE) for improved code density.

The TMP1942 is built on a TX19 core processor and a selection of intelligent peripherals. The TMP1942 is suitable for low-voltage, low-power applications.

Features of the TMP1942 include the following:

#### **RESTRICTIONS ON PRODUCT USE**

The information contained herein is subject to change without notice. 021023\_D

TOSHIBA is continually working to improve the quality and reliability of its products. Nevertheless, semiconductor devices in general can malfunction or fail due to their inherent electrical sensitivity and vulnerability to physical stress. It is the responsibility of the buyer, when utilizing TOSHIBA products, to comply with the standards of safety in making a safe design for the entire system, and to avoid situations in which a malfunction or failure of such TOSHIBA products could cause loss of human life, bodily injury or damage to property.

In developing your designs, please ensure that TOSHIBA products are used within specified operating ranges as set forth in the most recent TOSHIBA products specifications. Also, please keep in mind the precautions and conditions set forth in the "Handling Guide for Semiconductor Devices," or "TOSHIBA Semiconductor Reliability Handbook" etc. 021023\_A

The TOSHIBA products listed in this document are intended for usage in general electronics applications (computer, personal equipment, office equipment, measuring equipment, industrial robotics, domestic appliances, etc.). These TOSHIBA products are neither intended nor warranted for usage in equipment that requires extraordinarily high quality and/or reliability or a malfunction or failure of which may cause loss of human life or bodily injury ("Unintended Usage"). Unintended Usage include atomic energy control instruments, airplane or spaceship instruments, transportation instruments, traffic signal instruments, combustion control instruments, medical instruments, all types of safety devices, etc. Unintended Usage of TOSHIBA products listed in this document shall be made at the customer's own risk. 021023\_B

• The products described in this document shall not be used or embedded to any downstream products of which manufacture, use and/or sale are prohibited under any applicable laws and regulations. 060106\_Q

The information contained herein is presented only as a guide for the applications of our products. No responsibility is
assumed by TOSHIBA for any infringements of patents or other rights of the third parties which may result from its use.
No license is granted by implication or otherwise under any patents or other rights of TOSHIBA or the third parties.
070122\_C

• The products described in this document are subject to foreign exchange and foreign trade control laws. 060925\_E

• For a discussion of how the reliability of microcontrollers can be predicted, please refer to Section 1.3 of the chapter entitled Quality and Reliability Assurance/Handling Precautions. 030619\_s

- (1) TX19 core processor
  - 1) Two instruction set architecture (ISA) modes: 16-bit ISA for code density and 32-bit ISA for speed
    - The 16-bit ISA is object-code compatible with the code-efficient MIPS16<sup>TM</sup> ASE.
    - The 32-bit ISA is object-code compatible with the high-performance TX39 family.
  - 2) Combines high performance with low power consumption.
    - High performance
    - Single clock cycle execution for most instructions
    - 3-operand computational instructions for high instruction throughput
    - 5-stage pipeline
    - On-chip high-speed memory
    - DSP function: Executes 32-bit x 32-bit multiplier operations with a 64-bit accumulation in a single clock cycle.
    - Low power consumption
    - Optimized design using a low-power cell library
    - Programmable standby modes in which processor clocks are stopped
  - 3) Fast interrupt response suitable for real-time control
    - Distinct starting locations for each interrupt service routine
    - Automatically generated vectors for each interrupt source
    - Automatic updates of the interrupt mask level
- (2) Internal RAM: FDUE/FDXBG: 20KB,CYUE/CZUE/CZXBG: 16 KB

Internal ROM: FDUE/FDXBG: 512KB,CYUE/CZXBG: 384KB,CYUE: 256 KB

ROM correction function (8 words x 4 blocks)

(For FDUE/FDXBG, only registers are available; data is not replaced.)

- (3) External memory expansion
  - 16-Mbyte off-chip address space for code and data
  - External bus interface with dynamic bus sizing for 8-bit and 16-bit data ports
- (4) 4-channel DMA controller
  - Interrupt- or software-triggered
- (5) 6 channel 8-bit PWM timer

(12 channel 8-bit interval timer, 6 channel 16-bit interval timer, 6 channel 8-bit PPG output)

- (6) 14 channel 16-bit timer(2 channels support 2-phase input pulse counter mode.)
- (7) 1 channel real-time counter (RTC)
- (8) 5 channel general-purpose serial interface(Supports both UART and synchronous transfer modes)
- (9) 1 channel serial bus interface
   Either I<sup>2</sup>C bus mode or clock-synchronous mode can be selected.
- (10) 16 channel 10-bit A/D converter (with internal sample/hold)Conversion time: 2 μs (throughput), 4 to 5 μs (latency)
- (11) 3 channel 10-bit D/A converter
- (12) Watchdog timer
- (13) 4 channel chip select/wait controller

- (14) Interrupt sources
  - 4 CPU interrupts: software interrupt instruction
  - 45 internal interrupts: 7 priority levels, with the exception of the watchdog timer interrupt
  - 29 external interrupts: 7 priority levels, with the exception of the NMI interrupt
    - The external sources include 14 KWUP sources, which are all assigned to a single interrupt vector, and 4 extended interrupts (INTB, INTC, INTD, and INTE), which are all assigned to a single interrupt vector with an identification flag. Thus, the actual number of external interrupt sources is 13.
- (15) 108 pin input/output ports
- (16) Three standby function
  - IDLE, SLEEP, and STOP
- (17) Dual clocks
  - RTC clock: Low-speed clock (32.768 kHz)
- (18) Clock generator
  - On-chip PLL (x4)
  - Clock gear: Divides the operating speed of the CPU by 1/2, 1/4 or 1/8
- (19) Operating voltage range: 2.7 to 3.6 V

PC and PF are 2.7 to 3.6 V or 4.5 to 5.25 V for 5 V-enabled ports.

- (20) Operating frequency
  - 32 MHz (Vcc  $\ge$  3.0 V)
  - 28 MHz (Vcc  $\ge$  2.7 V)
- (21) Package
  - 144-pin QFP (16 x 16 x 1.4 (t) mm, 0.4-mm pitch): FDUE/CZUE/CYUE
  - 177-pin CSP (13 x 13 x 1.4 (t) mm, 0.8-mm pitch): FDXBG/CZXBG

Note: TMP1942FDXBG (Package: 177-pin CSP) is under development.

TMP1942CY/CZ-4

### 2. Signal Descriptions

This section contains pin assignments for the TMP1942 as well as brief descriptions of the functions of the TMP1942 input and output pins.

#### 2.1 Pin Assignment

Table 2.1.1 shows TMP1942 pin assignment.

Pin No.	Pin Name	Pin No.	Pin Name	Pin No.	Pin Name	Pin No.	Pin Name
1	VREFH	37	P11/AD9/A9	73	P90/KEY8/DCLK	109	CVCC

### 2.2 Pin Usage Information

Table 2.2.1 lists the names and functions of the TMP1942's input/output pins.

Die Martin	# af D's		Sie 2.2.1 Pin Names and Functions	
	# of Pins	Туре	Function	
P00~P07	8	Input/output	Port 0: Individually programmable as input or output	
AD0~AD7		Input/output	Address (Lower): Bits 0-7 of the address/data bus	
P10~P17	8	Input/output		
AD8~AD15		Input/output	Address/Data (Upper): Bits 8-15 of the address/data bus	
A8~A15		Output	Address: Bits 8-15 of the address bus	
P20~P27	8	Input/output		
A0~A7		Output	Address: Bits 0-7 of the address bus	
A16~A23		Output	Address: Bits 16-23 of the address bus	
P30	1	Output	Port 30: Output-only	
RD		Output	Read Strobe: Asserted during a read operation from an external memory device	
<u>P31</u>	1	Output	Port 31: Output-only	
WR		Output	Write Strobe: Asserted during a write operation on D0-D7	
P32	1	Input/output	Port 32: Programmable as input or output (with internal pull-up resister)	
HWR		Output	Higher Write Strobe: Asserted during a write operation on D8-D15	
P33	1	Input/output	Port 33: Programmable as input or output (with internal pull-up resister)	
WAIT		Input	Wait: Causes the CPU to suspend external bus activity	
<u>P34</u>	1	Input/output	Port 34: Programmable as input or output (with internal pull-up resister)	
BUSRQ		Input	Bus Request: Asserted by an external bus master to request bus mastership	
P35	1	Input/output	Port 35: Programmable as input or output (with internal pull-up resister)	
BUSAK		Output	Bus Acknowledge: Indicates that the CPU has relinquished the bus in response to $$\overline{\rm BUSRQ}$$ .	
P36	1	Input/output	Port 36: Programmable as input or output (with internal pull-up resister)	
R/W		Output	Read/Write: Indicates the direction of data transfer on the bus: 1 = read or dummy cycle, 0 = write cycle	
P37	1	Input/output	Port 37: Programmable as input or output (with internal pull-up resister)	
DSU		Input	This pin is used to select the operating mode during reset. The TMP1940CYAF enters NORMAL mode when this pin is sampled high at the rising edge of $\overrightarrow{\text{RESET}}$ . This pin should not be pulled down to a logic 0 during a reset sequence. The TMP1940FDBF, which has an on-chip flash, uses this pin as an interface to the DSU tool. For details, refer to Part 4, <i>TMP1940FDBF</i> .	
P40	1	Input/output	Port 40: Programmable as input or output (with internal pull-up resister)	
		Output	Chip Select 0: Asserted low to enable external devices at programmed addresses	
P41	1	Input/output	Port 41: Programmable as input or output (with internal pull-up resister)	
CS1		Output	Chip Select 1: Asserted low to enable external devices at programmed addresses	
P42	1	Input/output	Port 42: Programmable as input or output (with internal pull-up resister)	
CS2		Output	Chip Select 2: Asserted low to enable external devices at programmed addresses	
P43	1	Input/output	Port 43: Programmable as input or output (with internal pull-up resister)	
CS3		Output	Chip Select 3: Asserted low to enable external devices at programmed addresses	
P44	1	Input/output	Port 44: Programmable as input or output	
SCOUT		Output	System Clock Output: Drives out a clock signal at the same frequency as the CPU	
			clock (high-speed or low-speed)	
P50~P57	8	Input	Port 5: Input-only	
AN0~AN7		Input	Analog input: Input to the A/D converter	
ADTRG		Input	External start request for the A/D converter (multiplexed with P57)	
P60~P67	1	Input/output	Port 6: Input-only	
AN8~AN15		Input	Analog input: Input to the A/D converter	
KEY0-KEY7		Output	Key on wake-up input (with internal pull-up resister) (dynamic pull-up selectable)	
P90	1	Input/output	Port 90: Programmable as input or output	
DSU (DCLK)		Output	DSU pin	
KEY8		Input	Key on wake-up input (with internal pull-up resister) (dynamic pull-up selectable)	

Table 2.2.1 Pin Names and Function	Table 2.2.1	Pin Names	and Functions
------------------------------------	-------------	-----------	---------------

Pin Name	# of Pins	Туре	Function				
P91	1	Input/output	Port 91: Programmable as input or output				
DSU (PCST2)		Output	DSU pin				
KEY9		Input	Key on wake-up input (with internal pull-up resister) (dynamic pull-up selectable)				
P92	1	Input/output	Port 92: Programmable as input or output				
DSU (PCST1)		Output	DSU pin				
TB40UT		Output	16-Bit Timer 4 Output: Output from 16-bit Timer 4				
P93	1	Input/output	Port 93: Programmable as input or output				
DSU (PCST0)		Output	DSU pin				
TB5OUT		Output	16-Bit Timer 5 Output: Output from 16-bit Timer 5				
P94	1	Input/output	Port 94: Programmable as input or output				
DSU		Output	DSU pin				
(SDSA0/TPC)							
TB6OUT		Output	16-Bit Timer 6 Output: Output from 16-bit Timer 6				
P95	1	Input/output	Port 95: Programmable as input or output				
DSU (DBGE*)		Input	DSU pin				
TB7IN0			16-Bit Timer 7 Input 0: Count/capture trigger input to 16-bit Timer 7				
P96	1	Input/output	Port 96: Programmable as input or output				
DSU (DINT*)		Input	DSU pin				
TB7IN1			16-Bit Timer 7 Input 1: Capture trigger input to 16-bit Timer 7				
P97	1	Input/output	Port 97: Programmable as input or output				
DSU		Input	DSU pin				
(DRESET)		_	16 Pit Timor 7 Output: Output from 16 bit Timor 7				
TB7OUT		Output	16-Bit Timer 7 Output: Output from 16-bit Timer 7				
PA0	1	Input/output	Port A0: Programmable as input or output				
TBOINO		Input	16-Bit Timer 0 Input 0: Count/capture trigger input to 16-bit Timer 0				
INT3		Input	Interrupt Request 3: Programmable to be high-level, low-level, rising-edge or falling-edge sensitive				
PA1	1	Input/output	Port A1: Programmable as input or output				
TB0IN1	1	Input	16-Bit Timer 0 Input 1: Capture trigger input to 16-bit Timer 0				
INT4		Input	Interrupt Request 4: Programmable to be high-level, low-level, rising-edge or				
		input	falling-edge sensitive				
PA2	1	Input/output	Port A2: Programmable as input or output				
TB0OUT		Output	16-Bit Timer 0 Output: Output from 16-bit Timer 0				
PA3	1	Input/output	Port A3: Programmable as input or output				
TB1IN0		Input	16-Bit Timer 1 Input 0: Count/capture trigger input to 16-bit Timer 1

Pin Name	# of Pins	Туре	Function
PF1	1	Input/output	Port F1: Programmable as input or output
RXD5		Input	Serial Receive Data 5
KEYD		Input	Key on wake-up input (with internal pull-up resister) (dynamic pull-up selectable)
PF2	1	Input/output	Port F2: Programmable as input or output
SCLK5		Input/output	Serial Clock Input/Output 5
CTS5		Input	Serial Clear-to-Send 5
			Programmable as an open-drain output
PF3	1	Input/output	Port F3: Programmable as input or output
SCK		Input/output	Clock input/output pin when the serial bus interface is in SIO mode
PF4	1	Input/output	Port F4: Programmable as input or output
SO		Output	Data transmission pin when the serial bus interface is in SIO mode
SDA		Input/output	Data transmission/reception pin when the serial bus interface is in I <sup>2</sup> C mode
			Programmable as an open-drain output
PF5	1	Input/output	Port F5: Programmable as input or output
SI		Input	Data reception pin when the serial bus interface is in SIO mode
SCL		Input/output	Clock input/output pin when the serial bus interface is in I <sup>2</sup> C mode
			Programmable as an open-drain output
PF6		Input/output	Port F6: Programmable as input or output
INT0		Input	Interrupt request 0: Individually programmable to be high-level, low-level, rising-edge or falling-edge sensitive.
ALE	1	Output	Address Latch Enable (This signal is driven out only when external memory is accessed)
TEST0	1	Input	Test pin
TEST1	1	Input	Test pin
RSTPUP	1	Input	When this pin is driven high (upon reset), pull-up for ports 3 and 4 is enabled. When this pin is driven low, pull-up is disabled.
DAOUT0-2	3	Output	D/A converter output
NMI	1	Input	Non-maskable Interrupt Request: Causes an NMI interrupt on the falling edge
BW0~1	2	Input	Set both AM0 and AM1 to 1.
PLLOFF	1	Input	This pin should be tied to logic 1 when the frequency multiplied clock from the PLL is used; otherwise, it should be tied to logic 0.
RESET	1	Input	Reset (with internal pull-up resister): Initializes the whole TMP1940CYAF
VREFH	1	Input	Input pin for high reference voltage for the A/D converter.
VREFL	1	Input	Input pin for low reference voltage for the A/D converter.
AVCC	1	_	Power supply pin for the A/D converter. This pin should always be connected to power supply even when the A/D converter is not used.
AVSS	1	_	Ground pin for the A/D converter. This pin should always be connected to ground even when the A/D converter is not used.
DAVCC	1	_	Power supply pin for the D/A converter. This pin should always be connected to power supply even when the D/A converter is not used.
DAVSS	1	—	Ground pin for the D/A converter. This pin should always be connected to ground even when the D/A converter is not used.
DAREFH	1	_	Reference voltage input pin for the D/A converter
X1/X2	2	Input/output	Resonator connecting pin
CVCC	1	_	Power supply pin for the oscillator
CVSS	1	_	Ground pin for the oscillator (0 V)
DVCC3	4		Power supply pins
DVCC51	1		Power supply pin (port F)
DVCC52	1		Power supply pin (port C)
DVSS	5		Ground pins (0 V)

Port C becomes a 5 V port when a 5 V power supply is connected to DVCC52.

Port F becomes a 5 V port when a 5 V power supply is connected to DVCC51.

Note: When the DSU is enabled, port 9 functions as the processor probe interfacing signal regardless of the setting of the port 9 control register (P9CR).

The following table lists the JTAG specific pins added to the CSP package:

Pin Name	# of Pins	Туре	Function
TRST	1 Input		JTAG reset pin (with internal pull-up resistor)
TCK	1	Input	JTAG clock pin (with internal pull-up resistor)
TDI	1	Input	JTAG data input pin (with internal pull-up resistor)
TDO	1	Output	JTAG data output pin
TMS	1	Input	JTAG mode switching input pin (with internal pull-up resistor)

#### 3. Functional Description

This section describes the functions and basic operation of each individual circuit block in the TMP1942 series devices.

#### 3.1 Processor Core

The TX1942 contains a high-performance 32-bit processor core (the TX19 processor core). For details of the operation of the processor core, refer to "TX19 Family Architecture".

Functions unique to the TMP1942, which are not explained in "TX19 Family Architecture", are described below.

Recommended power-on sequence:

In powering up this device, it is recommended that the DVCC3 be turned on first. At power-on, the pull-up resistors and input & output buffers pull-down resistors attached to the I/O ports of the 5V supply domain may rail become unstable or a through current may pass through the port until the DVCC3 has stabilized, when an injection order is not kept.

#### 3.1.1 Reset Operation

To reset the TMP1942,  $\overline{\text{RESET}}$  must be input Low (at 0) for at least 12 system clock cycles while the power supply voltage is within the rated operating range and the internal high-frequency oscillator is oscillating stably. (With the device operating at 32 MHz, this period is equal to 3 µs if the PLL is being used and 6 µs if the PLL is not being used.) After a reset the PLL-multiplied clock is specified by the setting of the PLLOFF pin and the clock gear is initialized to 1/8 mode.

To reset the TMP1942,  $\overline{\text{RESET}}$  must be asserted for at least 12 system clock periods after the power supply voltage and the internal high-frequency oscillator have stabilized. This time is typically 3 µs at 32 MHz when the on-chip PLL is utilized, and 6µs otherwise. After a reset, either the PLL-multiplied clock or an external clock is selected, depending on the logic state of the  $\overline{\text{PLLOFF}}$  pin. By default, the selected clock is geared down to 1/8 for internal operation.

The following occurs as a result of a reset:

- The System control coprocessor (CP0) registers within the TX19 core processor are initialized. For details, refer to the Architecture manual.
- The Reset exception is taken. Program control is transferred to the exception handler at a predefined address. This predefined location is called an exception vector, which directly indicates the start of the actual exception handler routine. The Reset exception is always vectored to virtual address 0xBFC0\_0000 (which is the same as for the Nonmaskable Interrupt exception).
- All on-chip I/O peripheral registers are initialized.
- All port pins, including those multiplexed with on-chip peripheral functions, are configured as either general-purpose inputs or general-purpose outputs.

#### 3.2 Memory Map

Figure 3.2.1 shows a memory map of the TMP1942.

#### 3.3 Clock/Standby Control

There are essentially two modes of clock operation: single-clock mode (which uses only the X1 and X2 pins) and dual-clock mode (which uses the X1 and X2 pins as well as the XT1 and XT2 pins).

Figure 3.3.1 shows the state transition diagram for each operation mode.

(b) State transition in dual-clock mode

#### A. When a clock generated by the PLL is used

B. When the PLL is not used

Figure 3.3.32 Default States When the PLL is Used and Those When the PLL is Not Used

fosc:	Clock frequency input via X1 and X2 pins
fs:	Clock frequency input via XT1 and XT2 pins
fpll:	Clock frequency multiplied (x4) by PLL
fc:	Clock frequency selected by setting of $\overline{\text{PLLOFF}}$ pin
fgear:	Clock frequency selected by SYSCR1 <gear1:gear0></gear1:gear0>
System clock fsys:	Clock frequency selected by SYSCR1 <sysck></sysck>
fperiph:	Input clock for peripheral I/O prescaler

#### TMP1942CY/CZ-17

#### 3.3.1 Block Diagram of Clock Circuits

- 1. Main system clock
  - A crystal can be connected between X1 and X2, or X1 can be externally driven with a clock.
  - <u>PLLOFF</u> The on-chip PLL can be enabled or disabled (bypassed) during reset by using the <u>PLLOFF</u> pin. When the PLL is enabled, the input clock frequency is multiplied by four.
  - The clock gear can be programmed to divide the clock by 2, 4 or 8. (The default is 1/8 on reset.)
  - Input clock frequency

		Input Frequency Range	fmax	fmin
PLLON (for both resona	ator and external input)	5~8 (MHz)	32 MHz	2.5 MHz
	Resonator	16~20 (MHz)	20 MHz	1 MHz
PLLOFF	External input	16~20 (MHz)	20 MHz	1 MHz
	External input	20~32 (MHz)	16 MHz *1	1.25 MHz

\*1. SYSCR1<DFOSC> must be 0. The default is 0.

- 2. Sub-system clock
  - Generated using a 32.768-kHz resonator (external input also accepted).
  - SLOW mode: The CPU runs at low speed.
  - SLEEP mode: Only the timer for real-time clock, 2-phase pulse input counter, and dynamic pull-up operate.

3. Block diagram

Note 1: When using the clock gear to reduce the system clock frequency, make sure that  $\phi$ Tn of the prescaler output for each peripheral I/O block satisfies the following relationship:

φTn<fsys/2

To this end, set the clock-related registers so that  $\phi$ Tn is slower than fsys/2. When selecting a low-speed system clock (fs), only the timer for real-time clock, 2-phase pulse input counter, and dynamic pull-up can operate.

### 3.3.2 Clock Generator (CG) Registers(1) Clock-related registers

#### TOSHIBA

Note 1: Standby mode selection depends on the settings of the Doze and Halt bits in the CP0's internal Config register. If the Halt bit = 1, the device will enter the mode selected by STBY[1:0]. If the Doze bit = 1, the device will always enter IDLE mode. Note 2: When the PLL is not used, set the LUPTM bit in the SYSCR3 register to 1 (i.e., select 2<sup>12</sup>/input frequency). Note3: The WURT1-WUPT0 bitys in the SYSCR2 must be not be changed during the oscillator warm-up event (e.g. SLEEP-NORMAL-SLEEP) Note 4: Do as follows to change the operating mode immediately after the device has warmed up from the clock stop state (e.g., from SLEEP mode to NORMAL mode to SLEEP mode). Warming up by hardware (1) Moving from STOP or SLEEP mode to NORMAL mode 1) When the PLL is used Before moving to the next operating mode, ensure that the lock-up bit, LUPFG, in the SYSCR3 register has been cleared to zero and wait for five or more instructions to complete (including the instruction to check the LUPFG flag). 2) When the PLL is not used • When the oscillator warm-up time (SYSCR2<WUPT1:0>) is programmed as "01" (i.e., 2<sup>8</sup>/input frequency). Before moving to the next operating mode, ensure that the lock-up bit, LUPFG, in the SYSCR3 register has been cleared to zero and wait for five or more instructions to complete. • When the oscillator warm-up time (SYSCR2<WUPT1:0>) is programmed as "10" (2<sup>14</sup>/input frequency) or "11" ( $2^{16}$ /input frequency). Before moving to the next operating mode, wait for five or more instructions to complete. (2) Moving from STOP or SLEEP mode to SLOW mode It is possible to move to SLOW mode immediately after the device has warmed up from STOP or SLEEP mode. Warming up by software (1) Moving from SLOW mode to NORMAL mode 1) When the PLL is used It is possible to move to NORMAL mode immediately after the device has warmed up. However, to move to another mode after that, ensure that the lock-up bit, LUPFG, in the SYSCR3 register has been cleared to zero and wait for five or more instructions to complete (including the instruction to check the LUPFG flag). 2) When the PLL is not used • When the oscillator warm-up time (SYSCR2<WUPT1:0>) is programmed as "01" (i.e., 2<sup>8</sup>/input frequency). It is possible to move to NORMAL mode immediately after the device has warmed up. However, to move to another mode after that, ensure that the lock-up bit, LUPFG, in the SYSCR3 register has been cleared to zero and wait for five or more instructions to complete. • When the oscillator warm-up time (SYSCR2<WUPT1:0>) is programmed as "10" (2<sup>14</sup>/input frequency) or "11" (2<sup>16</sup>/input frequency). It is possible to move to NORMAL mode immediately after the device has warmed up. However, to move to another mode after that, wait for five or more instructions to complete. (2) Moving from NORMAL mode to SLOW mode Before moving to SLOW mode, ensure that the warm-up end flag (i.e., the WUEF bit in the SYSCR0 register) is cleared and wait for five or more instructions to complete.

	After reset	_	_	1	0	—	_		0
	Function			These bits sh be set to 11.	nould always				INTRTCEN request input 0: Disable 1: Enable

Note 1: When enabling an interrupt source as a means of terminating a standby mode, always set the active state for the corresponding interrupt request. Note 2: When using an interrupt, always perform the following steps in order: (1) Enable the input for the interrupt if the corresponding pin is also used for a general-purpose port or any other purpose. (2) Set the active state for the interrupt during initialization. (3) Clear the interrupt request. (4) Enable the interrupt. Note 3: The TMP1942 has eight interrupt sources (INT0~INT4, INTRTC, INTB/INTC/INTD/INTE, and KWUP0-KWUPD) which can be used as a means of terminating a standby mode. For INT0 to INT4, use the CG block to specify whether they are used to terminate a standby mode and to specify their active edge or level. For INTB/INTC/INTD/INTE and KWUP0-KWUPD, use the CG block to specify whether they are used to terminate a standby mode and use INTBCDEST and KWUPSTn, respectively, to specify their active edge or level. Set the active state for the corresponding interrupt source to High in the INTC block. Example: Enable the INT0 interrupt IMCGA0 < EMCG01:00 > = "10" CG block (Input is enabled on the falling edge.) IMCGA0<INT0EN> = "1" IMC0L<EIM11:10> = "01" INTC block IMC0L<IL12:10> = "101" (A High-level interrupt is active and the interrupt level is 5.) All interrupt sources other than those which are used to terminate STOP/SLEEP mode are set in the INTC circuit block. Note 4: Among the above eight interrupt sources used to request the termination of a standby mode, INTO to INT4 do not require settings in the CG block if they are used as normal interrupts. They still, however, require level or edge specification in the INTC. If INTB/INTC/INTD/INTE and KWUP0-KWUPD are used as normal interrupts, specify the active level or edge using INTBCDEST/KWUPSTn and specify the High level in the INTC. Settings in the CG are not required. INTRTC always requires settings in both the CG and INTC even if it is used as a normal interrupt. All interrupt sources other than those which are used to terminate a standby mode are set in the

INTC circuit block.

(2) Interment as support along an addition

#### 3.3.3 System clock control unit

When reset, the device enters single-clock mode with the result that XEN = 1, XTEN = 0 and GEAR1:0 = 11; the system clock fsys is set to fc/8 (=  $fc \times 1/8$ ). (Since the PLL multiplies the original oscillation frequency by 4, fc equals to  $fosc \times 4$ , where fosc is the original oscillation frequency.) For example, if the X1 and X2 pins are connected to an 8-MHz resonator, a reset will set fsys to 4 MHz (= 8 MHz × 4 × 1/8).

To disable the system from using a PLL-multiplied clock as the system clock by default, drive the  $\overline{\text{PLLOFF}}$  pin Low. In this case, too, the system clock fsys will be set to fc/8 (= fc × 1/8) by a reset. However, since SYSCR1<DFOSC> is initialized to 0 by a reset (so that fc = fosc × 1/2), if the X1 and X2 pins are connected to a 25-MHz resonator, fsys will be 1.25 MHz. Also, if the device is clocked by an external oscillator and no internal resonator is connected, fc = fosc can be selected by setting SYSCR1<DFOCS> to 1 after a reset, so that the system clock frequency fsys is twice the frequency obtained with an internal resonator.

(1) Oscillation settling time (switchover between NORMAL and SLOW modes)

If a resonator is connected to the resonator-connecting pins, the device uses the built-in warm-up timer to check whether resonator oscillation has settled. The warm-up time can be set to suit the characteristics of the resonator using SYSCR2<WUPT1:WUPT0>. The value of SYSCR0<WUEF> must be checked in software (using instructions) to determine the start and completion of the warm-up time.

Table 3.3.1 shows warm-up times for mode switching.

Note 1: Warm-up is unnecessary when the clock generator uses an oscillator so that its oscillation is stable.
Note 2: Since the warm-up timer is clocked by an oscillating clock, it will not be exact if the oscillation frequency fluctuates. The warm-up time should, therefore, be considered to be an approximate value.
Note 3: Before starting the warm-up timer, first confirm that the PLL lock-up flag <LUPFG> is 0.
Note 4: The following precautions must be observed when a low-speed oscillator is being used: When a low-speed oscillator is connected to ports PD6 and PD7, the corresponding register must be set as shown below in order to reduce the device's power consumption.
(When using a resonator)

Set PDCR<PD6C, PD7C> to 11 and PD<PD6, PD7> to 00. (When using an external clock)

Set PDCR<PD6C, PD7C> to 11 and PD<PD6, PD7> to 10.

Warm-Up Time Selection SYSCR2 <wupt1:0></wupt1:0>	High-Speed Clock (fosc)	Low-Speed Clock (fs)	The values calculated
(2 <sup>2</sup> /oscillation frequency)	0.5 [μs]	122 [μs]	are for when
(2 <sup>8</sup> /oscillation frequency)	32 [μs]	7.8 [ms]	fosc = 8 MHz and fs = 32.768 kHz.
(2 <sup>14</sup> /oscillation frequency)	2.048 [ms]	500 [ms]	
(2 <sup>16</sup> /oscillation frequency)	8.192 [ms]	2000 [ms]	

Table 3.3.1 Warm-Up Time

Note: When returning from STOP/SLEEP mode to NORMAL or SLOW mode, set the warm-up time to 122 µs or greater beforehand.

Example: If the device will return from SLEEP mode to SLOW mode, set SYSCR2<WUPT1:0> to 00, that is, a warm-up time of 122 µs, before entering SLEEP mode.

(2) Outputting the system clock from a pin

The system clock fsys or fs can be output from the P44/SCOUT pin to an external device. The P44/SCOUT pin can be set to function as the SCOUT pin by setting the registers which relate to port 4 as follows: P4CR < P44C > = 1 and P4FC < P44F > = 1. Use SYSCR3 < SCOSEL > to select which clock will be output from this pin.

Table 3.3.2 shows the pin state for each standby mode when the P44/SCOUT pin is set to function as SCOUT.

Mode	NORMAL,		Standby Mode	
SCOUT Selection	SLOW	IDLE	SLEEP	STOP
<scosel> = "0"</scosel>	Outputs fs clock.			Fixed to 0 or 1
<scosel> = "1"</scosel>	Outputs fsys clock.			

Table 3.3.2 SCOUT Output State for Each Standby Mode

Note: This function does not guarantee a particular phase difference (AC timing) between the internal clock and the system clock output from SCOUT.

(3) Reducing the driving capability of oscillators

If a resonator is connected to the resonator-connecting pins of an oscillator, this function can suppress oscillation noise output from the oscillator, while reducing power consumption by the oscillator.

Setting SYSCR2<DRVOSCH> to 1 causes the driving capability of the high-speed oscillator to degrade (Weak). Similarly, setting SYSCR2<DRVOSCL> to 1 causes the driving capability of the low-speed oscillator to degrade (Weak).

Because both bits are initialized to 0 upon a system reset, both oscillators start oscillating with their normal driving capability (Normal) when the power is turned on. The oscillators must be placed in the Normal state (<DRVOSCL> or <DRVOSCH> = 0) when they start oscillating in any other cases, such as when STOP/SLEEP mode is terminated.

1) Reducing the driving capability of the high-speed oscillator

2) Reducing the driving capability of the low-speed oscillator

#### 3.3.4 Prescaler clock control unit

The internal I/O blocks (TMRA01 to TMRAAB, TMRB0 to TMRBD, SIO0 to SIO5, SBI, and ADC) each incorporate a prescaler for dividing the clock frequency. The clock  $\phi$ T0 fed into these prescalers is derived from the clock fperiph. fperiph is either fgear or fc (as specified by the value of SYSCR1<FPSEL>) divided by either 4 or 2, or not divided (as specified by the value of SYSCR0<PRCK1:PRCK0>. By default, fperiph is set to fgear and  $\phi$ T0 to fperiph/4.

#### 3.3.5 Clock multiplication circuit (PLL)

This circuit multiplies the high-speed oscillator output clock, fosc, by 4 and outputs the result as the clock fpll. This enables the oscillator to yield a fast internal clock with a low oscillator frequency. The PLL is halted by a reset. To use the PLL, hold the  $\overline{PLLOFF}$  pin High when terminating a reset.

Note: If a reset is terminated while the PLLOFF pin is held Low, the PLL will not work and the internal clock chosen will be the original oscillating clock (i.e., it will not be multiplied by 4).

Since the PLL is configured as an analog circuit, it requires a certain settling time (a lock-up time) after it has been activated, as does the oscillator.

The same timer is used for both warm-up and lock-up. The lock-up time must be set using SYSCR3<LUPTM> so that it satisfies the following relationship:

Lock-up time  $\geq$  warm-up time

By default, the lock-up time is  $2^{16}$ /input frequency.

The lock-up timer is initiated as the high-speed oscillator starts warm-up, and the lock-up flag SYSCR3<LUPTM> remains 1 until the PLL is locked in phase and cleared to 0 upon the completion of lock-up.

If, for example, the PLL gets out of lock in a standby mode and control which depends on the software's execution speed, such as real-time processing, is to be performed, the software must check the lock-up flag after operation has started (i.e., after warm-up has been completed) to ensure that the clock has settled, before it starts processing.

On the other hand, various hardware settings and static processing, such as register and memory initialization, can be executed before the lock-up flag has been cleared.

Note: The LUPFG bit is undefined when the PLLOFF pin is Low (the PLL is not used).

Precautions to be observed when switching clock gear:

Clock gear switchover is performed by writing a value to SYSCR1<GEAR1:GEAR0>. The clock gear is not switched immediately after the write: a execution time equal to several clock cycles is required. Therefore, one or more instructions following the clock gear switchover instruction may be executed using the old clock gear value. If these instructions need to be executed using the new clock gear value, insert a dummy instruction (which executes a write cycle only) after the clock gear switchover instruction.

When using a clock gear, make sure that the prescaler output  $\phi$ Tn in each peripheral I/O block satisfies the following relationship:

 $\phi$ Tn < fsys/2

For this purpose set the clock-related registers so that  $\phi$ Tn is slower than fsys/2.

#### 3.3.6 Standby control unit

If the Halt bit in the TX19 processor core's Config register is set in NORMAL mode, the device enters one of the standby modes - IDLE, SLEEP or STOP - as determined by the contents of SYSCR2<STBY1:STBY0>. If the Config register's Doze bit is set, the device enters IDLE mode regardless of the setting of SYSCR2<STBY1:STBY0>.

Features of the IDLE, SLEEP and STOP modes are described below.

1) IDLE: In this mode, only the CPU stops.

In the register corresponding to each module there is an IDLE mode run/stop setup bit for internal I/O. This allows each module to be set independently to run or stop while the device is in IDLE mode. Table 3.3.3 lists the IDLE setup registers available for each internal I/O module.

Internal I/O	IDLE Mode Setup Register
TMRA01	TA01RUN <i2ta01></i2ta01>
TMRA23	TA23RUN <i2ta23></i2ta23>
TMRA45	TA45RUN <i2ta45></i2ta45>

Table 3.3.3	IDLE Mode Internal I/O	Setup Registers
-------------	------------------------	-----------------

- Note 1: In Halt mode (entered when the Halt bit in the Config Register is set), the TX19 processor core stops processor operation while maintaining the pipeline status. Since it does not respond to requests for control of the bus from internal DMA, it retains control of the bus.
- Note 2: In Doze mode (entered when the Doze bit in the Config Register is set), the TX19 processor core stops processor operation while maintaining the pipeline status. In this mode, it can respond to requests for control of the bus from devices external to the processor core.
  - 2) SLEEP: Only the internal low-speed oscillator, timer for real-time clock, 2-phase pulse input counter, and KWUP (dynamic pull-up) operate.
  - STOP: The CPU runs with the low-speed clock. The INTC, timer for real-time clock, WDT, 2-phase pulse input counter, KWUP (dynamic pull-up), PIO, and EBIF can operate. Operation of other peripheral functions is not guaranteed.
  - 4) SLOW: All of the internal circuits stop.

(1) Operating status in each mode

Table 3.3.4	Operating	Status in	Each Mode
-------------	-----------	-----------	-----------

Operation Mode	Operating Status
NORMAL	The TX19 processor core and peripheral I/O both operate at the maximum frequency.
IDLE (Halt)	The TX19 processor core, INTC, timer for real-time clock, WDT, 2-phase pulse input counter, KWUP (dynamic pull-up), PIO, and EBIF operate with the low-speed clock.
IDLE (Doze)	Processor operation stops and peripheral I/O operates as specified.
SLEEP	Processor operation stops. Only the internal low-speed oscillator, timer for real-time clock, 2-phase pulse input counter, and KWUP (dynamic pull-up) operate (fs).
STOP	Processor and peripheral I/O operation stops completely.

(2) CG operation in each mode

Table 3.3.5 CG Status in Each Operating Mode	Status in Each Operating Mode
--	-------------------------------

CG	_	0	0	0	×

\*1: DAC output is controlled with the OP bit for each channel.

(4) Terminating a standby mode

The device can be freed from a standby mode by an interrupt request or a reset. The combination of the interrupt mask register <CMask15:13> setting and the current standby mode determines which interrupt source will be used to terminate the standby mode. The interrupt mask register is part of the Status register in the TX19 processor core's system control coprocessor (CP0). Details are given in Table 3.3.7.

• Termination by an interrupt request

The operation performed when the device is released from a standby mode by an interrupt request varies according to the interrupt enable status. If the interrupt level which was set before the device entered the standby mode is greater than or equal to the value in the interrupt mask register, the processor services the requested interrupt after exiting the standby mode and then begins executing instructions starting with the one following the instruction to enter the standby mode (i.e., the instruction which specified the appropriate Config register bit). If the interrupt request level is less than the value in the interrupt mask register, the processor immediately begins executing instructions starting with the one following the instruction to enter the standby mode (i.e., the instruction starting with the one following the instruction to enter the standby mode (i.e., the instruction which specified the appropriate Config register bit) without servicing the requested interrupt. (The interrupt request flag remains 1.)

Non-maskable interrupts are always serviced after standby mode has terminated, irrespective of the value of the mask register.

Termination by a reset

The device can be released from any standby mode by a reset. However, after release from STOP mode, a certain reset time is required for oscillator operation to settle. The reset selects a warm-up time of  $2^{14}$ /oscillation frequency.

After release by a reset, the internal RAM data can be retained in the state in which it was placed immediately before the standby mode was entered; however, all other settings will be initialized. (After released by an interrupt, other settings are also retained in the state in which they were placed immediately before the standby mode was entered.)

Table 3.3.7 Standby Termination Sources and Standby Termination Operation

Ifter exiting the standby mode, the processor starts servicing the interrupt. (RESET initializes the LSI.)
 Ifter exiting the standby mode, the processor begins executing instructions starting with the one following the instruction to enter the standby mode, without servicing the interrupt.

- ×: Cannot be used to exit from a standby mode.
- \*1: The device is actually released from the standby mode after the warm-up time has passed.
- \*2: Only INTTB2 and INTTB3 can be used when 2-phase pulse input counter mode is selected.
- Note 1: When using a level-sensitive interrupt to terminate a standby mode, be sure to hold the level until the processor starts servicing the interrupt. If the level is changed before that time, the interrupt cannot be serviced properly.
- Note 2: If the interrupts are disabled in the CPU, use the interrupt controller (INTC) to disable only the interrupts other than those used for terminating standby, before placing the device in any of the standby modes.
  - (5) STOP mode

In STOP mode all internal circuits, including the internal oscillator, stop operating. The pin state in STOP mode varies according to the setting of SYSCR2<DRVE>, as shown in Table 3.3.10. Once released from STOP mode, the device waits for a while (until the warm-up time ends) before starting to output the system clock; the warm-up time is counted by the warm-up counter. This delay is to ensure that the internal oscillator settles properly. After exiting STOP mode the device starts operating according to the settings of SYSCRO<RXEN, RXTEN, RSYSCK>, which select the operating mode (NORMAL mode or SLOW mode) to be entered on exit from STOP mode.

These settings must be made before the instruction to enter standby mode is executed. The warm-up time is determined by the setting of SYSCR2<WUPT1:WUPT0>.

- -: Pins configured for input mode and input-only pins are disabled. Pins configured for output mode and output-only pins assume the high-Impedance state.
- Input: The input gate is active; the input voltage must be held at either the high or low level to keep the input pin from floating.

Output: Pin direction is output.

PU\*: Programmable pull-up. Because the input gate is always disabled, no overlap current flows while in high-impedance state.

## 3.4 Interrupts

Interrupts are controlled by the Status<CMask15:13> and Status<IEc> settings in the CP0 status register, as well as by the internal interrupt controller and the CG. For related information, refer to Section 5, "Exception Handling" in "TX19 Family Architecture".

Interrupts in the TMP1942 have the following features:

- Interrupts from the CPU itself (software interrupt instructions): 4 sources
- External interrupt pins ( NMI , INTO-INTE, KWUPO-KWUPD): 30 sources
- Interrupts from internal I/O: 46 sources
- Vector generation for each interrupt source
- 7 interrupt priority levels for each source
- Can be used to activate the DMAC

- Note 1: Standby termination is performed via the CG detection circuit. Since its output is a High-level active signal, the INTC must be set to accept a High-level active signal.
- Note 2: The CG is bypassed for any processing other than standby termination. In that case, the active conditions for INT0 to INT4 must be set in the INTC.
- Note 3: INTRTC requires CG settings for both standby termination and other processing. The INTC must be set to accept a High-level active signal.
- Note 4: KWUP and INTB to INTD require settings in each circuit block for both standby termination and other processing. The INTC must be set to accept a High-level active signal.

Figure 3.44.1 Interrupt Connection Diagram

(1) External interrupts INT0 to INT4, INTB to INTE, KWUP0 to KWUPD, and INTRTC

## 1) INT0 to INT4

When used to terminate a standby mode, these interrupts must have their active state set (using IMCGxx<EMCGxx>) and must be enabled for input (using IMCGxx<INTxEN>) in the CG block. Then the active state of each of the interrupt source must be set to High (by setting IMCxx<EIMxx> to 01) in the INTC block. When these interrupts are not used to terminate a standby mode, set their active state in the INTC block.

2) INTB to INTE

When used to terminate a standby mode, these interrupts must have their active state set to High (by setting IMCGB2<21:20> to 10) and must be enabled for input (by setting IMCGB2<16> to 1) in the CG block. Then the active state of each of the interrupt source must be set to High (by setting IMCxx<EIMxx> to 01) in the INTC block. Use INTnST for each interrupt source to set the active state and enable or disable the interrupt. When these interrupts are not used to terminate a standby mode, make necessary settings in the INTC block and INTnST without having to make settings in the CG.

## 3) KWUP0 to KWUPD

When used to terminate a standby mode, these interrupts must have their active state set to High (by setting IMCGB1<21:20> to 10) and must be enabled for input (by setting IMCGB1<16> to 1) in the CG block. Then the active state of each of the interrupt source must be set to High (by setting IMCxx<EIMxx> to 01) in the INTC block. Use KWUPSTn for each interrupt source to set the active state and enable or disable the interrupt. When these interrupts are not used to terminate a standby mode, make necessary settings in the INTC block and KWUPSTn without having to make settings in the CG.

4) INTRTC

Regardless of whether INTRTC is used to terminate a standby mode, this interrupt must have its active state set to a rising edge (by setting IMCGB3<29:28> to 11) and must be enabled for input (by setting IMCGB3<24> to 1) in the CG block. Then the active state of each of the interrupt source must be set to High (by setting IMCxx<EIMxx> to 01) in the INTC block.

(2) External interrupts INT5 to INTA and internal interrupt signals (other than INTRTC) All these interrupts must be set in the INTC block.

The INTC resolves priority conflicts between interrupt sources and notifies the TX19 processor core of the interrupt with the highest priority.

Interrupt		Register to be Set	Usable Interrupt Detection Level		
		IMCGx reg.In CG IMCx reg.In INTC	When used to terminate a standby mode, the interrupt source active state must be set to High in the INTC block. The active state of these interrupts must be selected in the CG. However, when these interrupts are not used terminate a standby mode, their active state must be selected in the INTC block. In both cases, Low level, High level, falling edge and rising edge are acceptable.		
INTB~INTE		IMCGx reg.In CG IMCx reg.In INTC INTnST	The interrupt source active state must always be set to High in the INTC block. When these interrupts are used to terminate a standby mode, the interrupt source active state must also be set to High in the CG. The active state of these interrupts must be selected in INTnST. However, when these interrupts are not used to terminate a standby mode, settings in the CG are not necessary. In both cases, Low level, High level, falling edge and rising edge are all acceptable.		
KWUP0~D		IMCGx reg.In CG IMCx reg.In INTC KWUPSTn	The interrupt source active state must always be set to High in the INTC block. When these interrupts are used to terminate a standby mode, the interrupt source active state must also be set to High in the CG. The active state of these interrupts must be selected in KWUPSTn. However, when these interrupts are not used to terminate a standby mode, settings in the CG are not necessary. In both cases, Low level, High level, falling edge and rising edge are all acceptable.		
INT5~INTA		IMCx reg.In INTC	Low level, High level, falling edge and rising edge are all acceptable in the INTC.		
Internal I/O	INTDMAn	IMCx reg.In INTC	Falling edge		
	Others	IMCx reg.In INTC	Rising edge		

Note 1: Interrupt level 0 indicates that the corresponding interrupt is disabled.

Note 2: Only a rising edge can be used for INTRTC.

• Example interrupt settings When INT0 is used to request the termination of STOP/SLEEP mode (falling edge)

a. Enabling the interrupt	
IMCGA0 <emcg01:00> = "10"</emcg01:00>	: Select falling edge for INT0

# TOSHIBA

## 3.4.1 Interrupt sources

- Reset and non-maskable interrupts: RESET , NMI and INTWDT (watchdog timer interrupt) Vector address: 0xBFC0\_0000 (virtual address)
- (2) Maskable interrupts: Software and hardware interrupts

Vector addresses: 0xBFC0\_0210 (virtual address) to 0xBFC0\_0260 (virtual address)

Interrupt Source		Vector Address (virtual address)
Reset		0xBFC0 0000
Non-maskable		
	Software Swi0	0xBFC0_0210
ble	Swi1	0xBFC0_0220
Maskable	Swi2	0xBFC0_0230
Ma	Swi3	0xBFC0_0240
	Hardware	0xBFC0_0260

- Note 1: When vector addresses are located in the on-chip ROM, set the BEV bit in the system control coprocessor (CP0) Status register to 1.
- Note 2: Maskable software interrupts are generated by setting <Sw3:Sw0> in CP0 Cause register. Do not confuse these software interrupts with Software Set, which is one of the hardware interrupt sources. The Software Set interrupt is generated by setting <IL02:IL00> in the interrupt controller (INTC) IMC0 register to any value other than 0.

#### 3.4.2 Interrupt detection

When using interrupts to terminate a standby mode, the following settings are necessary according to the interrupt type: Interrupts INT0 to INT4 have their active state set using the EMCGxx field in the CG's internal IMCGxx register, then the EIMxx field in the INTC's internal IMCx register is set to High. Extended interrupts INTB to INTE have their active state set to High using the EMCG field in the CG's internal IMCGB2 register, then the EIMxx field in the INTC's internal IMCx register is set to High. In addition, INTnST is used to set the active state for each interrupt source and enable/disable the interrupt source. KWUP0 to KWUPD have their active state set to High using the EMCG field in the CG's internal IMCGB1 register, then the EIMxx field in the INTC's internal IMCx register is set to High. In addition, KWUPSTn is used to set the active state for each interrupt source and enable/disable the interrupt source.

The RTC interrupt has its active state set to a rising edge using the EMCGxx field in the CG's internal IMCGxx register, then the EIMxx field in the INTC's internal IMCx register is set to High. Other interrupts have their active state set using only the EIMxx field in the INTC's internal IMCx register. The active state can be one of the following four: rising edge, falling edge, High level or Low level. When the TMP1942 detection circuit recognizes the active state of an interrupt request set in this way, it notifies the processor core or the INTC of the interrupt request. When the above interrupts are not used to terminate a standby mode, settings in the CG are not required: INT0 to INT4 require only settings in the INTC, INTB to INTE require the same settings in the INTC as for standby termination as well as setting in INTnST, and KWUPD to KWUPD require the same settings in the INTC as for standby termination as well as setting in KWUPSTn.

Cancellation of interrupt signals is carried out by the interrupt handler after it has recognized the requested interrupt.

INTB to INTE are canceled by reading INTFLG.

Interrupt signals from INT0 to INT4 and INTRTC are cancelled by writing the appropriate value to the ICRCG field in the CG's internal EICRCG register and then writing the corresponding value to the EICLR field in the INTC's internal INTCLR register. KWUP0 to KWUPD are canceled by setting KWUPCLR. Other interrupt signals are canceled by writing the appropriate value to the EICLR field in the INTC's internal INTCLR register. These cancellation procedures apply regardless of whether the active state is an edge or level.

\* The INTRTC interrupt must have its active state set to a rising edge in the CG even when it is not used for standby termination.

Figure 3.44.2	Flow for Setting External Interrupts
---------------	--------------------------------------

Note: Each stage must be completed in the following sequence: set the active level, clear the interrupt request, and then enable the interrupt.

## (Example of setting INT0 for standby termination)

IMCGA0 <emcg01:00> = "10"</emcg01:00>	: Select falling edge for INT0
EICRCG <icrcg2:0> = "000"</icrcg2:0>	: Clear interrupt request for INTOC > G block
IMCGA0 <int0en> = "1"</int0en>	: Enable request input for INT0
IMC0L <eim11:10> = "01"</eim11:10>	: Select High level for INT0
INTCLR <eiclr5:0> = "000001"</eiclr5:0>	: Clear interrupt request for INT0 > INTC block
IMC0L <il12:10> = "101"</il12:10>	: Set interrupt level to 5
Status <iec> = "1", <cmask> = "xxx"</cmask></iec>	TX19 processor core

## 3.4.3 Resolving interrupt priority

(1) Seven interrupt priority levels

The TMP1942 has seven interrupt priority levels; thus for each interrupt source the priority can be set to one of seven levels.

The interrupt mode control register (IMCx) is used for setting interrupt levels. This register includes a 3-bit level-setting field (ILx). The greater the value (interrupt level) set in IMC<ILx2:ILx0>, the higher the interrupt priority. If the value set for an interrupt source in this field is 000 (i.e., the interrupt level is set to 0), no interrupt is generated for that interrupt source.

### (2) Notification of the interrupt level

When an interrupt occurs, the INTC notifies the TX19 processor core of the priority level of the interrupt. The TX19 processor core recognizes the interrupt level by reading the IL field in the Cause register. If multiple interrupts (with different priority levels) occur simultaneously, the TX19 processor core is notified of the interrupt with the highest priority.

#### (3) Interrupt vector (notification of interrupt source)

When an interrupt occurs, the INTC also sets the vector for the source of the generated interrupt in the vector register (IVR). The TX19 processor core reads the vector register to determine the interrupt source. If multiple interrupts (with the same priority level) occur simultaneously, the TX19 processor core is notified of the vector for the interrupt source with the smallest request number. When there are no interrupt sources for which an interrupt has occurred, the IVR[9:4] field is 0.

When it is time for the TX19 processor core to read the vector register value, the INTC notifies the processor core. The processor core sets the Status<CMask> bit with the interrupt level which it reads.

# 3.4.4 INTC registers

Address	Register Symbol	Register	Corresponding Interrupt Number
0xFFFF_E060	INTCLR	Interrupt request clear control	ALL (63 – 0)
0xFFFF_E040	IVR	Interrupt vector register	ALL (63 – 0)

# 3.5 I/O Ports

The TMP1942 has 108 I/O port pins. All the port pins except a few share pins with alternate functions. They can be individually programmed as general-purpose I/O or dedicated I/O for the on-chip CPU or peripherals.

Port	Pin Name	# of Pins	Direction	Pull Resistor	Direction Programmability	Alternate Functions
Port 0	P00~P07	8	Input/output		Bitwise	AD0~AD7
Port 1	P10~P17	8	Input/output		Bitwise	AD8~AD15 A8~A15
Port 2	P20~P27	8	Input/output		Bitwise	A0~A7 A16~A23
	P30	1	Output		Bitwise	RD
	P31	1	Output		Bitwise	WR
	P32	1	Input/output	Pull up	Bitwise	HWR
Port 3	P33	1	Input/output	Pull up	Bitwise	WAIT
Poil 3	P34	1	Input/output	Pull up	Bitwise	BUSRQ

--	-------------	----------	-----------------	-------

X: Don't care

Pn: Port n Register, PnCR: Port n Control Register, PnFC: Port n Function Register

\*: Set this bit when using the pin for a STOP mode termination interrupt with SYSCR<DRVE> set to 0. Otherwise, the bit need not be set.

Note 1:  $\overline{HWR}$ ,  $R/\overline{W}$  and P40 to P43 have their internal pullup resistors enabled when the corresponding P4FC register bit is set and when the bus is released.

Note 2: When P50–P57 are configured as analog channels of the ADC, the ADCH[2:0] field in A/D Mode Control Register 1 (ADMOD1) is used to select a channel(s).

Note 3: When P57 is configured as **ADTRG**, the ADTRGE bit in the ADMOD1 register is used to enable and disable the external trigger input to the ADC.

Note 4: When PD6–PD7 are configured as XT1–XT2, the SYSCR0 register must be programmed to enable oscillation, etc.

Note 5: When PortD and PortE and PortF are configured as SDA and SCL outputs for the SBI, the ODEA[7:6] field in the Open-Drain Enable (ODE) register can be used to configure them as either push-pull or open-drain ouptuts. Upon reset, the default is push-pull.

## 3.5.1 Port 0 (P00-P07)

Port 0 is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. Use the control register POCR to set the port for input or output. A reset clears all bits of POCR to 0 and puts port 0 in input mode.

In addition to functioning as a general-purpose input/output port, this port can also function as an address/data bus (AD0-AD7). When external memory is accessed, this port automatically functions as an address/data bus (AD0-AD7), with all bits of POCR cleared to 0.

Figure 0.1 Port 0 (P00-P07)

Note: The above system diagram does not represent the address/data bus function.

## 3.5.2 Port 1 (P10-P17)

Port 1 is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register P1CR and function register P1FC are used to set the port for input or output. A reset clears all bits of output latch P1 and all bits of P1CR and P1FC to 0, putting port 1 in input mode.

In addition to functioning as a general-purpose input/output port, this port can also function as an address/data bus (AD8-AD15) or an address bus (A8-A15). To access external memory, set this port to an address bus or address/data bus using P1CR and P1FC.

Figure 0.3 Port 1 (P10-P17)

Note: The above system diagram does not represent the address/data bus function.

### 3.5.3 Port 2 (P20-P27)

Port 2 is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register P2CR and function register P2FC are used to set the port for input or output. A reset sets all bits of output latch P2 to 1 and clears all bits of P2CR and P2FC to 0, putting port 2 in input mode.

In addition to functioning as a general-purpose input/output port, this port can function as an address bus (A0-A7 or A16-A23).

Port 2 Control Register

### TOSHIBA

### 3.5.4 Port 3 (P30-P37)

Port 3 is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output, with the exception that P30 and P31 are output-only. The control register P3CR and function register P3FC are used to set the port for input or output. A reset sets bits P30, P31 and P37 of the output latch to 1. Bits P32 to P36 are set to 1 by a reset if RSTPUP is High or cleared to 0 if RSTPUP is Low. All bits of P3CR (bits 0 and 1 not used) and P3FC (bits 3 and 7 not used) are cleared to 0 by a reset, with P30 and P31 outputting a High signal and P32 to P36 placed in input mode with pull-up resistors enabled (if RSTPUP is High) or disabled (if RSTPUP is Low). P37 is placed in input mode with a pull-up resistor enabled regardless of the value of RSTPUP.

In addition to functioning as a general-purpose input/output port, this port can also input and output the CPU's control and status signals. The RD strobe is output only when an external address area is being accessed while the P30 pin is set for RD output ( $\langle P30F \rangle = 1$ ). Similarly, the WR strobe is output only when an external address area is being accessed while the P31 pin is set for WR output ( $\langle P31F \rangle = 1$ ).

P32 and P36 have their pull-up resistors enabled when BUSAK = 0 while  $\langle P3xFC \rangle = 1$ .

Port 3 Register

### 3.5.5 Port 4 (P40-P44)

Port 4 is a 5-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register P4CR and function register P4FC are used to set the port for input or output. Bits P41 to P44 of the output latch register are set to 1 by a reset if RSTPUP is High or cleared to 0 if RSTPUP is Low. Bit P44 of the output latch register is set to 1 regardless of the value of RSTPUP. All bits of P4CR and P4FC are cleared to 0 by a reset, with P40 to P43 placed in input mode with pull-up resistors enabled (if RSTPUP is High) or disabled (if RSTPUP is Low). P44 is placed in input mode with a pull-up resistor disabled regardless of the value of RSTPUP.

In addition to functioning as a general-purpose input/output port, P40-P43 can also output the chip select signals (CS0-CS3), and P44 functions as the SCOUT pin, outputting the system clock.

### Port 5 Register

Figure 0.16 Port 5 (P50-P57)

Note 1: Use A/D converter mode register ADMOD4 to select A/D converter input channels and to enable A/D trigger input for P57.

Note 2: To use  $\overline{\text{ADTRG}}$ , first set <P57F> to 1 and then enable trigger input in A/D converter mode register ADMOD4. To stop using  $\overline{\text{ADTRG}}$ , first disable trigger input in ADMOD4 and then clear <P57F> to 0 (port).

### 3.5.7 Port 6 (P60-P67)

Port 6 is an 8-bit input-only port, and is shared with the A/D converter's analog input pins and key input pins. A reset clears P6FC to 0, placing port 6 in A/D or port input mode. Writing a 1 to a bit of P6FC enables the corresponding pin to be used as a key input pin. Port 6 has pull-up resistors, which are enabled only for those pins for which KWUPCNT<PE> is set to 1 in the key on wake-up circuit and key input is enabled in KWUPSTn. For details, refer to the description of the key on wake-up function.

### 3.5.8 Port 9 (P90-P97)

Port 9 is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register P9CR is used to set the port for input or output. A reset clears P9CR to 0, putting port 9 in input mode. In addition to functioning as an input/output port, the pins of this port can also function as various input/output pins: P90 and P91 function as key input, P92 to P94 and P97 as 16-bit timer output, and P95 and P96 as 16-bit timer input. These functions are enabled by setting the corresponding bits of P9FC to 1.

A reset clears P9CR and P9FC to 0, placing port 9 in input mode. Pins P90 and P91 have pull-up resistors, which are enabled only for those pins for which KWUPCNT<PE> is set to 1 in the key on wake-up circuit and key input is enabled in KWUPSTn. For details, refer to the description of the key on wake-up function. When a pin is functioning as a port pin, its pull-up resistor is disabled.

When the DSU is enabled, port 9 functions as a DSU interface regardless of the settings in P9CR and P9FC, so that the pins cannot be used as general-purpose port pins or peripheral function pins as described above.

### 3.5.9 Port A (PA0-PA7)

Port A is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register PACR is used to set the port for input or output. A reset clears PACR to 0, putting port A in input mode. In addition to functioning as an input/output port, the pins of this port can also function as various input/output pins: PA0, PA1, PA3 and PA4 function as 16-bit timer input or external interrupt input, PA2 and PA5 as 16-bit timer output, PA6 as 8-bit timer output, and PA7 as 8-bit timer input or key input. These functions are enabled by setting the corresponding bits of PAFC to 1.

A reset clears PACR and PAFC to 0, placing port A in input mode. PA7 has a pull-up resistor, which is enabled only when KWUPCNT<PE> is set to 1 in the key on wake-up circuit and key input is enabled by setting 1 in PAFC. When the pin is functioning as a port pin, its pull-up resistor is disabled.

(\*1) Set this bit when using the pin for a STOP mode termination interrupt with SYSCR<DRVE> set to 0. Otherwise, the bit need not be set.

For a pin to which two input functions are assigned in addition to the port function, use Note: the control register for each function module to specify which function is used.

Figure 3.5.24 Registers Related to Port A

### 3.5.10 Port B (PB0-PB7)

Port B is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register PBCR is used to set the port for input or output. A reset clears PBCR to 0, putting port B in input mode. In addition to functioning as an input/output port, the pins of this port can also function as various input/output pins: PB0, PB1, PB3 and PB4 function as 16-bit timer input or external interrupt input, PB2 and PB5 as 16-bit timer input or output, PB7 as 8-bit timer input, interrupt input or key input. These functions are enabled by setting the corresponding bits of PBFC to 1.

A reset clears PBCR and PBFC to 0, placing port B in input mode. PB7 has a pull-up resistor, which is enabled only when KWUPCNT<PE> is set to 1 in the key on wake-up circuit and key input is enabled in KWUPSTn. For details, refer to the description of the key on wake-up function. When the pin is functioning as a port pin, its pull-up resistor is disabled.

(\*1) Set this bit when using the pin for a STOP mode termination interrupt with SYSCR<DRVE> set to 0. Otherwise, the bit need not be set.

Note: For a pin to which two or three input functions are assigned in addition to the port function, use the control register for each function module to specify which function is used.

Figure 3.5.28 Registers Related to Port B

### 3.5.11 Port C (PC0-PC7)

Port C is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register PCCR is used to set the port for input or output. A reset clears PCCR to 0, putting port C in input mode. In addition to functioning as an input/output port, the pins of this port can also function as various input/output pins: PC0, PC1 and PC2 function as 8-bit timer input or external interrupt input, PC3 and PC5 as 8-bit timer output, PC6 as 16-bit timer input or key input, PC4 as 8-bit timer input, and PC7 as 16-bit timer input or 8-bit timer output. These functions are enabled by setting the corresponding bits of PCFC to 1.

A reset clears PCCR and PCFC to 0, placing port C in input mode. PC6 has a pull-up resistor, which is enabled only when KWUPCNT<PE> is set to 1 in the key on wake-up circuit and key input is enabled in KWUPSTn. For details, refer to the description of the key on wake-up function. When the pin is functioning as a port pin, its pull-up resistor is disabled.

Port C becomes a 5 V input/output port when 5 V is supplied to its dedicated power supply pin DVCC52. It becomes a VCC-based (3 V) port when VCC is supplied to DVCC52.

Note: For a pin to which two input functions are assigned in addition to the port function, use the control register for each function module to specify which function is used.

Figure 3.5.32 Registers Related to Port C

### 3.5.12 Port D (PD0-PD7)

Port D is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register PDCR is used to set the port for input or output. A reset clears PDCR to 0, putting port D in input mode. In addition to functioning as an input/output port, the pins of this port can also function as various input/output pins: PD0 and PD3 function as 16-bit timer input or SIO data output, PD1 and PD4 function as 16-bit timer input or SIO data input, PD2 as SIO serial clock input/output or CTS\*input, and PD5 as SIO serial clock input/output, CTS\*input, or 16-bit timer output. PD6 and PD7 can be connected to a low-frequency oscillator. These functions are enabled by setting the corresponding bits of PDFC1 to 1. For PD5, however, a combination of PDFC1 and PDFC2 determines whether it is used for a port, SIO, or timer. The output open-drain control register (PDODE) can be used to set PD0, PD2, PD3 and PD5 to open-drain output when they are used for output. PD6 and PD7 are always open-drain output when they are used for output.

A reset clears PDCR, PDFC1 and PDFC2 to 0, placing port D in input mode.

Figure 3.5.33 Port D (PD0, PD3)

Figure 3.5.34 Port D (PD1, PD4, PD2)

Note: The output mode is selected by a combination of PDFC1 and PDFC2. When PDFC1<bit 5> = 0 and PDFC2<bit 5> = 0, port output is selected. When PDFC1<bit 5> = 1 and PDFC2<bit 5> = 0, SCLK output is selected. When PDFC1<bit 5> = 0 and PDFC2<bit 5> = 1, TABOUT output is selected. Setting both PDFC1<bit 5> and PDFC2<bit 5> to 1 is not allowed.

### 3.5.13 Port E (PE0-PE7)

Port E is an 8-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register PECR is used to set the port for input or output. A reset clears PECR to 0, putting port E in input mode. In addition to functioning as an input/output port, the pins of this port can also function as various input/output pins: PEO and PE3 function as SIO data output, PE1 and PE4 as SIO data input, PE2 and PE5 as SIO CLK input/output or CTS\* input, and PE6 and PE7 as external interrupt input. These functions are enabled by setting the corresponding bits of PEFC to 1.

A reset clears PECR and PEFC to 0, placing port E in input mode. The output open-drain control register (PEODE) can be used to set PE0, PE2, PE3 and PE5 to open-drain output when they are used for output.

## 3.5.14 Port F (PF0-PF6)

Port F is a 7-bit general-purpose input/output port whose bits can each be set independently for input or output. The control register PFCR is used to set the port for input or output. A reset clears PFCR to 0, putting port F in input mode. In addition to functioning as an input/output port, the pins of this port can also function as various input/output pins: PF0 functions as SIO data output, PF1 as SIO data input or key input, PF2 as SIO CLK input/output or CTS\* input, PF3, PF4 and PF5 as SBI input/output, and PF6 as external interrupt input. These functions are enabled by setting the corresponding bits of PFFC to 1.

A reset clears PFCR and PFFC to 0, placing port F in input mode. The output open-drain control register (PFODE) can be used to set PF0, PF2, PF4 and PF5 to open-drain output when they are used for output. Port F becomes a 5 V input/output port when 5 V is supplied to its dedicated power supply pin DVCC51. It becomes a VCC-based (3 V) port when VCC is supplied to DVCC51.

## 3.6 External Bus Interface

The TMP1942 contains an external bus interface function which is necessary for connecting memory or I/Os which are external to the chip. This function is implemented by the external bus interface circuit (EBIF) and the CS (chip select)/wait controller.

The CS/wait controller specifies mapping addresses for any four address spaces, and controls a wait state and data bus width (8 bits or 16 bits) for these four address spaces and other external address spaces.

The external bus interface circuit (EBIF) controls timing for the external bus based on settings made with the CS/wait controller. The EBIF also controls dynamic bus sizing and the arbitration of bus contention with external bus masters.

• Wait function

Can be set individually for each block.

- A wait state of up to 7 clock cycles can be automatically inserted.
- Wait states can be inserted from the  $\overline{WAIT}$  pin.
- Data bus width

The bus width can be independently selected as 8 bits or 16 bits for each block.

Read recovery cycle

When a external bus cycle is immediately followed by a next external bus cycle, up to two dummy clock cycles can be inserted.

Insertion of the dummy cycle(s) can be set individually for each block.

• Control of ALE width

The ALE width can be set to 0.5 or 1.5 clock cycles.

The set ALE width applies to all blocks in common.

• Arbitration of bus contention

## 3.6.1 Address and data pins

(1) Setting address and data pins

For external memory connections, port 0 (AD0-AD7), port 1 (AD8-AD15/A8-A15) and port 2 (A16-A23/A0-A7) pins can be used as the address bus and the data bus. One of the following four bus configurations can be selected by setting up the port registers.

		(1)	(2)	(3)	(4)
Number of bus lines	address	max.24 (~16 MB)	max.24 (~16 MB)	max.16 (~64 KB)	max.8 (~256 B)
Number of data bus lines		8	16	8	16
	multiplexed ta bus lines	8	16	0	0
<b>D</b> .	Port 0	AD0 ~ AD7	AD0 ~ AD7	AD0 ~ AD7	AD0 ~ AD7
Port function	Port 1	A8 ~ A15	AD8 ~ AD15	A8 ~ A15	AD8 ~ AD15
Turrotion	Port 2	A16 ~ A23	A16 ~ A23	A0 ~ A7	A0 ~ A7
Timing diag	gram	A23-8 AD7-0 ALE RD	A23-16 A2	A15~0 A15~0 (Note1) AD7~0 (A7~0) (D7~0) ALE RD	A7~0 A7~0 (Note1) AD15~0 (A15~0) (D15~0) ALE RD

Note 1: Even for cases (3) and (4), addresses are output because the data bus pins are shared with the address bus.

Note 2: Ports 0 to 2 are set for input after a reset, and do not function as address or data bus pins. Note 3: Any one of (1) to (4) can be selected by setting the P1CR, P1FC, P2CR and P2FC registers as desired.

(2) Address hold when an internal area is accessed

When an internal area is accessed, the address bus retains the previous address which was output by the external area device; thus the address does not change. In addition, the address/data bus is placed in high-impedance state.

# TOSHIBA

## 3.6.2 External bus operation

This section explains various bus timings. In the following timing diagrams, the address bus is chosen to be A23-A16 and the address/data bus is chosen to be AD15-AD0.

(1) Basic bus operation

External bus cycles in the TMP1942 essentially consist of three clock cycles. A wait state can be inserted, as will be explained later. The basic clock for external bus cycles is the same as the internal system clock.

Figure 3.6.1 shows a read bus timing. Figure 3.6.2 shows a write bus timing. During internal access, the address bus does not change, as shown in the diagram, nor does ALE output a latch pulse. The address/data bus is placed in high-impedance state, and neither  $\overline{RD}$  and  $\overline{WR}$  nor other control signals are asserted.

Figure 3.6.1 Read Operation Timing Diagram

Figure 3.6.2 Write Operation Timing Diagram

Note: fsys expresses one period of share of system clock.

(2) Wait timing

Wait cycles can be inserted individually for each block by using the CS/wait controller. The following two types of wait insertion can be used:

- a. Automatic wait insertion of up to 7 clock cycles
- b. Wait insertion from  $\overline{WAIT}$  pin

Note: "Please set the number of wait as "+1" when you use = long and BUSRQ the ALE width."

Timing diagrams with a wait state inserted are shown below.

Figure 3.6.4 Read Operation Timing Diagram (1+N Wait Cycles, N = 1)

Figure 3.6.5 Write Operation Timing Diagram (with 0 Wait Cycles and 1 Wait Cycle)

Figure 3.6.6 Write Operation Timing Diagram (1+N Wait Cycles, N = 1)

## (3) ALE assertion time

The ALE assertion time can be selected as either 0.5 or 1.5 clock cycles. The bit for setting this assertion time is provided in the system clock control register. The default assertion time is 1.5 clock cycles. The assertion time cannot be set individually for blocks in the external area; it applies universally to the entire external address space.

Note: "Please set the number of wait as "+1" when you use = long and BUSRQ the ALE width."

Figure 3.6.7 ALE Assertion Time

Figure 3.6.8 shows read operation timing with an ALE assertion time of 0.5 clock cycles and that with an ALE assertion time of 1.5 clock cycles.

Figure 3.6.8 Read Operation Timing Diagram (with ALE Asserted for 0.5 and 1.5 Clock Cycles)

(4) Read recovery time

When an external access occurs after reading from an external area, a dummy cycle can be inserted to create a recovery time. Dummy cycles can only be inserted when the immediately preceding cycle is a read cycle.

External read followed by external read:	Can be inserted
External read followed by external write:	Can be inserted
External write followed by external access:	Cannot be inserted

The number of dummy cycles can be specified independently for each block as one clock cycle or two clock cycles. Use the CS/wait controller to set the number of clock cycles.

Figure 3.6.9 Read Recovery Time

As shown above, by adding two dummy clock cycles, a sufficient time from the rise of  $\overline{RD}$  to the output of the next address can be secured even when the device is operating at a fast clock speed. Figure 3.6.10 shows a bus timing diagram where one and two dummy clock cycles are inserted.

Figure 3.6.10 Read Operation Timing Diagram (with Dummy Cycles Inserted)

### 3.6.3 Bus arbitration

The TMP1942 allows external bus masters to be connected to the chip. Two signals  $\overline{\text{BUSRQ}}$  and  $\overline{\text{BUSAK}}$  are used to arbitrate contention for bus control between the processor and external bus masters. External bus masters can only gain control of buses external to the TMP1942. External bus masters cannot gain control of the device's internal bus.

(1) Access range for external bus masters

External bus masters can only gain control of buses external to the TMP1942. External bus masters cannot gain control of the device's internal bus (G-Bus). Therefore, external bus masters cannot access the device's internal memory and internal I/O blocks. Contention for control of the external bus is arbitrated by the external bus interface circuit (EBIF); hence the CPU and the internal DMAC are not involved in bus arbitration. Even when an external bus master has control of the external bus, the CPU and the internal DMAC can access the internal ROM and RAM and the internal registers. On the other hand, when the CPU or the internal DMAC attempts to access external memory while an external bus master has control of the external bus, the CPU or the internal DMAC is kept waiting until the external bus master finishes control of the external bus. Therefore, if BUSRQ remains asserted for an excessive period of time, the TMP1942 may get locked.

### (2) Gaining control of the bus

An external bus master requests control of the bus from the TMP1942 by asserting the  $\overline{\text{BUSRQ}}$  signal. The TMP1942 samples the  $\overline{\text{BUSRQ}}$  signal during a break in the external bus cycles on the internal bus (G-Bus) to determine whether or not to grant control of the bus. To give control of the bus to the external bus master, it asserts the  $\overline{\text{BUSAK}}$  signal. At the same time, it places the address bus, data bus and bus control signals in high-impedance state.

If the data size to be loaded or stored is larger than the width of the bus for the external memory, multiple bus cycles may occur for a single data transfer (bus sizing). In such a case, a break in the external bus cycles will occur when the last bus cycle has finished.

The TMP1942 allows the insertion of dummy cycles when external access continues for successive bus cycles. Even in this case it is only when a break in the external bus cycles occurs on the internal bus (G-Bus) that a request for bus control is accepted. During a dummy cycle the next external bus cycle is already activated on the internal bus, so that if the BUSRQ signal is asserted during a dummy cycle, the bus will only be released after the next bus cycle has been completed.

Make sure the  $\overline{\text{BUSRQ}}$  signal remains asserted until control of the bus has been finished. Figure 3.6.11 shows a timing sequence in which control of the bus is gained by an external bus master.

Note: "Please set the number of wait as "+1" when you use = long and BUSRQ the ALE width."

(1) BUSRQ is High.

- (2) The TMP1942 recognizes that BUSRQ has been pulled Low and releases the bus when the bus cycle has been completed.
- (3) The TMP1942 asserts BUSAK upon completion of the bus cycle. The external bus master recognizes that BUSAK has been asserted Low and gains control of the bus, thereby initiating its bus operation.

Figure 3.6.11 Timing at Which Control of the Bus is Gained

(3) Relinquishing control of the bus

An external bus master relinquishes control of the bus in the following case:

- When it no longer requires control of the bus
- 1) Relinquishing control of the bus when an external bus master no longer requires control of the bus.

When the external bus master no longer needs the control of the bus which it gained, it deasserts the  $\overline{\text{BUSRQ}}$  signal to return control of the bus to the TMP1942. Figure 3.6.12 shows a timing sequence in which the bus is released because the external bus master no longer requires control of it.

(1) The external bus master has control of the bus.

(2) Because the external bus master no longer requires control of the bus, it deasserts BUSRQ

(3) The TMP1942 recognizes that BUSRQ has reverted to High and responds by deasserting BUSAK.

Figure 3.6.12 Timing at Which Control of the Bus is Relinquished

(4) Bus Release Timings

Note: Gaddr indicates the address on the G-Bus. AD (addr) indicates the address on the address/data bus. Addr indicates the address on the address bus.

## 3.7 Chip Select/Wait Controller

The TMP1942 supports direct connections to external devices (I/O devices, ROM and SRAM).

The TMP1942 provides four programmable chip select signals. Programmable features include variable block sizes, data bus width, wait state insertion, and dummy cycle insertion for back-to-back bus cycles.

 $\overline{\text{CS0}}$  -  $\overline{\text{CS3}}$  (multiplexed with P40-P43) are the chip select output pins for the CS0-CS3 address ranges. These chip select signals are generated when the CPU or on-chip DMAC issues an address within the programmed ranges. The P40-P43 pins must be configured as CS0-CS3 by programming the Port 4 Control (P4CR) register and the Port 4 Function (P4FC) register.

Chip select address ranges are defined in terms of a base address and an address mask. There is a Base/Mask Address (BMAn) register for each of the four chip select signals, where n is a number from 0 to 3.

There is also a set of three Chip Select/Wait Control registers, B01CS, B23CS and BEXCS, each of which consists of a master enable bit, a data bus width bit, a wait state field and a dummy cycle field.

External memory devices can also use the  $\overline{WAIT}$  pin to insert wait states and consequently prolong read and write bus cycles.

### 3.7.1 Programming Chip Select Ranges

Each of the four chip select address ranges is defined in the BMAn register. The basic chip select model allows one of the chip select output signals ( $\overline{CS0} - \overline{CS3}$ ) to assert when an address on the address bus falls within a particular programmed range. The B01CS register defines specific operations for CS0 and CS1, and the B23CS register defines specific operations for CS2 and CS3 (see Section 3.7.2).

### (1) Base/Mask Address Registers

The organizations of the BMAn registers are shown in Fig.3.7.1 and Fig. 3.7.2. The base address (BAn) field specifies the starting address for a chip select. Any set bit in the address mask field (MAn) masks the corresponding base address bit. The address mask field determines the block size of a particular chip select line. The address is compared on every bus cycle.

### /Base address

The base address (BAn) field specifies the upper 16 bits (A31-A16) of the starting address for a chip select. The lower 16 bits (A15-A0) are assumed to be zero. Thus, the base address is any multiple of 64 Kbytes starting at 0x0000\_0000. Figure 3.7.3 shows the relationships between starting addresses and the BMAn values.

### /Address mask

The address mask (MAn) field defines whether any particular bits of the address should be compared or masked. Any set bit masks the corresponding base address bit. The address compare logic uses only the address bits that are not masked (i.e., mask bit cleared to 0) to detect an address match.

Address bits that can be masked (i.e., supported block sizes) differ for the four chip select spaces as follows:

CS0 and CS1 spaces: A29-A14

CS2 and CS3 spaces: A30-A15

Note: Use physical addresses in the BMAn registers.

	Base/mask ad	ddress regi	sters BMA	A0 (0xFFFF	_E400) to	BMA3 (0x	FFFF_E40	C)

Base/mask address registers BMA0 (0xFFFF\_E400) to BMA3 (0xFFFF\_E40C)

Note: Bits 10-15 in BMA0 and BMA1 must always be set to 0. This is because, although the CS0 and CS1 spaces can have a size of 16 KB to 1 GB, the TMP1942's external address space is limited to 16 MB, which requires setting bits 10-15 to 0 so as not to mask the A24-A29 address bits.

Note: Bits 9-15 in BMA2 and BMA3 must always be set to 0.

This is because, although the CS2 and CS3 spaces can have a size of 32 KB to 2 GB, the TMP1942's external address space is limited to 16 MB, which requires setting bits 9-15 to 0 so as not to mask the A24-A30 address bits.

Figure 3.7.2 Base/Mask Address Registers (BMA2 and BMA3)

Figure 3.7.3 Relationship Between Start Address and Base Address Register Values

(2) Setting the start address and address space size

• Program the BMA0 register as follows to cause CS0 to be asserted in the 64 Kbytes of address space starting at 0xC000\_0000.

The BA0 field specifies the upper 16 bits of the starting address, or 0xC000. The MA0 field determines whether the A29-A14 bits of the address should be compared or masked. The A31 and A30 bits are always compared. Bits 15-10 of the MA0 field must be cleared so that the A29-A24 bits are always compared.

When the BMA0 register is programmed as shown above, the A31-A16 bits of the address are compared to the value of the BA0 field. Consequently, the 64-Kbyte address range between  $0xC000\_0000$  and  $0xC000\_FFFF$  is defined as the  $\overline{CS0}$  space.

• Program the BMA2 register as follows to cause CS2 to be asserted in the 512 Kbyte of address space starting at 0x1FC8\_0000.

The BA2 field specifies the upper 16 bits of the starting address, or 0x1FC8. The MA2 field determines whether the A30-A15 bits of the address should be compared or masked. The A31 bit is always compared. Bits 15-9 of the MA0 field must be cleared so that the A30-A24 bits are always compared.

When the BMA2 register is programmed as shown above, the A31-A19 bits of the address are compared to the value of the BA2 field. Consequently, the 1-Mbyte address range between 0x1FC8\_0000 and 0x1FCF\_FFFF is defined as the CS2 space.

```
Note: The TMP1942 does not assert any CSn signal in the following address ranges:
0xFFFF_8000 through 0x1FFF_BFFF
```

Upon reset, the CS0, CS1 and CS3 spaces are disabled while the CS2 space is enabled and spans the entire 4-GB address space.

(3) Specifying the size of an address space

Table 3.7.1 shows the possible sizes of each CS space. If two or more address spaces are specified which overlap one another, the address space with the lowest CS space number will be selected since it has priority.

Example: The start address of the CS0 space is 0xC000\_0000 and the space size is 16 Kbytes. The start address of the CS1 space is 0xC000\_0000 and the space size is 64 Kbytes.

Size (Bytes) CS Space	16 K	32 k	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M	16 M
CS0	0	0	0	0	0	0	0	0	0	0	0
CS1	0	0	0	0	0	0	0	0	0	0	0
CS2		0	0	0	0	0	0	0	0	0	0
CS3		0	0	0	0	0	0	0	0	0	0

#### 3.7.2 Chip select/wait control registers

The chip select/wait control registers are shown in Figure 3.7.4 to Figure 3.7.6. For each address space (i.e., the CS0-CS3 spaces and any other address space), the corresponding chip select/wait control register (B01CS-B23CS or BEXCS) can be used to enable/disable the master, select a chip select output waveform and data bus width, set the number of wait cycles and insert dummy cycles. If two or more address spaces are specified which overlap one another, the address space with the lowest CS space number will be selected since it has priority. (The priority order is CS0 > CS1 > CS2 > CS3 > EXCS.)

## 3.7.3 Example of Use

Figure 3.7.7 shows an example of a TMP1942 system configuration with external memory connected. In this example a 128-Kbyte ROM is connected with a data width of 16 bits and 256-Kbyte RAM is connected with a data width of 16 bits.

## 3.8 DMA Controller (DMAC)

The TMP1942 incorporates a four-channel DMA controller.

## 3.8.1 Features

The DMAC included in the TMP1942 has the following features:

- (1) Independent 4-channel DMA
- (2) Two types of request for control of the bus: with snoop request or without snoop request
- (3) Transfer request: Internal transfer request: Start by software External transfer request: Request by interrupt
- (4) Transfer mode: Dual-address mode
- (5) Transfer devices: Memory-to-memory, memory-to-I/O, I/O-to-memory
- (6) Device size: 32 bits for memory (16 or 8 bits can also be specified using the CS/wait controller); 8, 16 or 32 bits for I/O
- (7) Address change: Increment, decrement, fixed, irregular increment or irregular decrement
- (8) Channel priority: Fixed

## 3.8.2 Configuration

### 3.8.2.1 Internal connections in the TMP1942

Figure 3.8.1 shows how the DMAC is connected internally within the TMP1942.

Figure 3.8.1 Internal Connection of DMAC Within the TMP1942

The DMAC has four DMA channels. These channels each receive a data transfer request signal (INTDREQn) from the interrupt controller and return an acknowledge signal ( $\overline{DACKn}$ ) in response to INTDREQn. The letter 'n' denotes the channel number: 0 to 3. Channel 0 has priority over channel 1, channel 1 has priority over channel 2 and channel 2 has priority over channel 3.

The TX19 processor core has a snoop function. The snoop function entails the TX19 processor core releasing the core data bus to the DMAC so that the DMAC can access the internal ROM or internal RAM connected to the TX19 processor core. The DMAC can choose whether or not to use the snoop function. For details of the snoop function, refer to Section 3.8.2.3, "Snoop function".

There are two types of request for bus control: SREQ and GREQ. The type which is selected depends on whether or not the DMAC is using the snoop function. GREQ is used to request control of the bus when the snoop function is not in use and SREQ is used to request control of the bus when the snoop function is in use. An SREQ bus request has higher priority than a GREQ bus request.

Note : DMA channel priority exists only among those using the same type of bus request signal(SREQ or GREQ).For example, once a given DMA channel has acquired bus mastership using SREQ, no other DMA channel can assume bus mastership using GREQ until the ongoing DMA transaction is completed.

### 3.8.2.2 Internal blocks of the DMAC

Figure 3.8.2 shows the internal blocks of the DMAC.

Figure 3.8.2 Internal Blocks of the DMAC

### 3.8.2.3 Snoop function

The TX19 processor core has a snoop function. This function is used to release the TX19 processor core's data bus to the DMAC.

When the snoop function is activated, the TX19 processor core releases its data bus to the DMAC. At the same time the TX19 processor core stops operating and remains idle until control of the data bus is returned to it by the DMAC. Since the DMAC can access the processor's internal RAM or internal ROM while the snoop function is active, the RAM or ROM can be specified as the source or destination of a transfer.

The TMP1942's internal DMAC can select whether or not to use the TX19 processor core's snoop function. If the DMAC chooses to use the snoop function, it can then access the processor's internal RAM and internal ROM. The CPU in the TX19 processor core will then be stalled until the DMAC cancels the bus request.

If the DMAC chooses not to use the snoop function, it cannot access the processor's internal RAM or internal ROM. However, since in this case too the G-Bus is released to the DMAC, if the TX19 processor core attempts to access memory or I/O via the G-Bus and the DMAC does not respond to the request for release of bus control, the TX19 processor core will not be able to execute bus operation, and as a result the pipeline will stall.

Note: When the snoop function is not used, the TX19 processor core does not release the data bus to the DMAC. Therefore, if the processor's internal RAM or internal ROM is specified as the source or destination of a DMA transfer, no acknowledge signal will be returned for the DMAC's transfer cycle, resulting in the bus being locked.

# 3.8.3 Registers

The DMAC incorporates twenty-six 32-bit registers. Table 3.8.1 shows the DMAC register map.

Address	Register Symbol	Register Name
0xFFFF_E200	CCR0	Channel control register (ch. 0)
0xFFFF_E204	CSR0	Channel status register (ch. 0)
0xFFFF_E208	SAR0	Source address register (ch. 0)
0xFFFF_E20C	DAR0	Destination address register (ch. 0)
0xFFFF_E210	BCR0	Byte count register (ch. 0)
0xFFFF_E218	DTCR0	DMA transfer control register (ch. 0)
0xFFFF_E220	CCR1	Channel control register (ch. 1)
0xFFFF_E224	CSR1	Channel status register (ch. 1)
0xFFFF_E228	SAR1	Source address register (ch. 1)
0xFFFF_E22C	DAR1	Destination address register (ch. 1)
0xFFFF_E230	BCR1	Byte count register (ch. 1)
0xFFFF_E238	DTCR1	DMA transfer control register (ch. 1)
0xFFFF_E240	CCR2	Channel control register (ch. 2)
0xFFFF_E244	CSR2	Channel status register (ch. 2)
0xFFFF_E248	SAR2	Source address register (ch. 2)
0xFFFF_E24C	DAR2	Destination address register (ch. 2)
0xFFFF_E250	BCR2	Byte count register (ch. 2)
0xFFFF_E258	DTCR2	DMA transfer control register (ch. 2)
0xFFFF_E260	CCR3	Channel control register (ch. 3)
0xFFFF_E264	CSR3	Channel status register (ch. 3)
0xFFFF_E268	SAR3	Source address register (ch. 3)
0xFFFF_E26C	DAR3	Destination address register (ch. 3)
0xFFFF_E270	BCR3	Byte count register (ch. 3)
0xFFFF_E278	DTCR3	DMA transfer control register (ch. 3)
0xFFFF_E280	DCR	DMA control register (DMAC)
0xFFFF_E28C	DHR	Data-holding register (DMAC)

# Table 3.8.1 DMAC Registers

: Initial value

Bit	Mnemonic	Field Name	Description
31	Rst	Reset	Reset (initial value: —)
			Resets the DMAC by software. When the Rst bit is set to 1, all of the DMAC's internal registers are reset to their initial values. Also, all transfer requests are canceled and the four DMA channels are turned off.
			0: Don't care
			1: Initialize the DMAC.

Figure 3.8.3 DMA Control Register (DCR)

- Note1: When the snoop request is disabled (CCRn.SReq=0), a software reset of the DMAC must be performed in the following sequence:
  - 1. Disable interrupts.
  - 2. Execute NOP four times.
  - 3. Perform a software reset.
  - 4. Perform a software reset again.
  - 5. Re-enable interrupts.
  - Execute steps 3 and 4 consecutively.
- Note 2: If the software reset command is written to the DCR register immediately after the completion of the last transfer cycle of a DMA transaction, the DMA-done interrupt will not be cleared. In this case, the software reset only initializes channel registers, etc.

Note 3: Don't issue a software reset command to the DCR register via a DMA transfer.

3.8.3.2 Channel control registers (CCF	Rn)
--	-----

Bit	Mnemonic	Field Name	Description
31	Str	Channel Start	Start (initial value: —)
			Starts channel operation. When this bit is set to 1, the channel enters ready state. Data transfer can now commence as soon as a transfer request is received.
			1 is the only valid value which can be written to this bit; if a 0 is written, it is ignored. When read, this bit always appears to be 0.
			1: Start channel operation.
24	_	(Reserved)	This bit is reserved. Make sure that it is always set to 0.
23	NIEn	Normal Completion	Normal Completion Interrupt Enable (initial value: 1)
		Interrupt Enable	1: Enable normal completion interrupts.
			0: Disable normal completion interrupts.
22	AblEn	Abnormal Completion	Abnormal Completion Interrupt Enable (initial value 1)
		Interrupt Enable	1: Enable abnormal completion interrupts.
			0: Disable abnormal completion interrupts.
21	—	(Reserved)	This bit is reserved. Although this bit is initially set to 1, make sure that it is always set to 0.
20	_	(Reserved)	This bit is reserved. Make sure that it is always set to 0.
19	_	(Reserved)	This bit is reserved. Make sure that it is always set to 0.
18	_	(Reserved)	This bit is reserved. Make sure that it is always set to 0.
17	Big	Big-Endian	Big-Endian (initial value: 1)
			1: The channel operates in big endian mode.
			0: The channel operates in little endian mode.
			On the TMP1942, set this bit to 0.
16	_	(Reserved)	This bit is reserved. Make sure that it is always set to 0.
15	_	(Reserved)	This bit is reserved. Make sure that it is always set to 0.
14	ExR	External Request Mode	External Request Mode (initial value: 0)
			Specifies the transfer request mode.
			1: External transfer request (interrupt-driven start)
			0: Internal transfer request (soft start)
13	PosE	Positive Edge	Positive Edge (initial value: 0)
			Specifies the valid level for the transfer request signal INTDREQn. This specification is effective only when the transfer request is an external transfer request (i.e., when the ExR bit = 1). In the case of internal transfer requests (i.e., when the ExR bit = 0) the value of PosE is ignored. Be sure to set the PosE bit to 0 and the adjacent Lev bit to 1.

Figure 3.8.4 Channel Control Registers (CCRn) (1/2)

12 Level Mode Level Mode (initial value: 0)	n
Specifies the method for requesting extension specification is effective only when the transfer request (i.e., when the ExR bit transfer requests (i.e., when the ExR bit ignored. Be sure to set the Lev bit to 1.	ransfer request is an external = 1). In the case of internal
11 SReq Snoop Request Snoop Request (initial value: 0)	
Specifies whether or not the snoop funct control request mode. When the function TX19 processor core's snoop function is the DMAC can use the processor core's is not selected for use, the TX19 process remains inactive. 1: The snoop function is used (i.e., the of 0: The snoop function is used (i.e., the of 0) The snoop function i	n is selected for use, the s activated with the result that data bus. When the function sor core's snoop function device is in SREQ mode).

#### 3.8.4 Functions

This section describes the functions of the DMAC.

#### 3.8.4.1 Outline

The DMAC is a 32-bit DMA controller capable of performing high-speed data transfers in a system incorporating the TX19 processor core without the need for any intervention by the TX19 processor core itself.

#### (1) Source and destination

The DMAC performs data transfers between one memory device and another or between a memory device and an I/O device. The device from which data is transferred is referred to as the source device and the device to which data is transferred is referred to as the destination device. Both memory devices and I/O devices can be specified as the source and destination devices. However, the DMAC can only transfer data from a memory device to an I/O device, from an I/O device to memory, or from memory to memory; it cannot transfer data between two I/O devices.

The difference between memory devices and I/O devices resides in the methods by which the devices are accessed. When the DMAC accesses an I/O device, it asserts the DACKn signal. Because only one DACKn signal line is available for each channel, the DMAC can only perform one data transfer involving an I/O device at a time; hence the DMAC cannot transfer data from one I/O device to another.

An interrupt source can be specified for transfer requests to the DMAC. When an interrupt occurs, the interrupt controller generates a request to the DMAC. (In this case, no interrupt request to the TX19 processor core is generated. For details, refer to Section 3.4, "Interrupts".) This interrupt request from the interrupt controller is canceled by the DACKn signal. Therefore, when an I/O device has been set as a transfer device, a request to the DMAC is cancelled for each transfer performed (i.e., each time the amount of data specified by the TrSiz bits is transferred). On the other hand, in memory-to-memory transfers, DACKn is asserted only when the number of bytes to be transferred (as specified by the value of the BCRn register) falls to 0; hence several data transfers can be performed successively by a single transfer request.

For example, when the DMAC is transferring data between the TMP1942's internal I/O and internal (or external) memory, although a transfer request from the internal I/O to the DMAC is cancelled for each transfer performed, the DMAC is kept waiting for the next transfer request unless the number of bytes to be transferred (as specified by the value of the BCRn register) falls to 0. Consequently, DMA transfer is performed successively until the BCRn register value is reduced to 0.

(2) Switching control of the bus (bus arbitration)

When a transfer request is issued by the DMAC' s internal circuitry, the DMAC requests control of the bus from the TX19 processor core. If an acknowledge signal is returned by the TX19 processor core, the DMAC gains control of the bus and can perform data transfer bus cycles.

The DMAC can request two types of bus control: either bus control plus the use of the TX19 processor core's data bus (i.e., the snoop function), or bus control without the snoop function. This can be set independently for each channel in the corresponding register.

The TX19 processor core may request release of bus control from the DMAC. Whether the DMAC should respond to this request is set using independent register settings for each channel. However, this response function is effective only when the DMAC does not request the snoop function (i.e., in GREQ mode). When the snoop function is requested (i.e., in SREQ mode), the response function will have no effect because the TX19 processor core cannot generate requests for release of bus control in this mode.

When there are no more transfer requests, the DMAC will finish control of the bus.

Note1: The NMI interrupt is left pending while the DMAC has control of the bus. Note2: Do not place the TMP1962 in Halt power-down mode while the DMAC is operating.

(3) Transfer request modes

The DMAC has two transfer request modes: internal transfer request mode and external transfer request mode.

In internal transfer request mode, transfer requests are generated internally in the DMAC. A transfer request is generated by setting the start bit in one of the DMAC's internal registers (the channel control register's Str bit) to 1, upon which the DMAC will start a transfer operation.

In external transfer request mode, transfer requests are generated by assertion of the transfer request signal (INTDREQn), which is output by the interrupt controller after the start bit has been set to 1. The DMAC can select level mode, in which a transfer request is generated on detection of a High- or Low-level INTDREQn signal, or edge mode, in which a transfer request is generated on detection of the rising or falling edge of the INTDREQn signal. However, because the INTDREQn signal in the TMP1942 is low-active, always make sure that the transfer request signal is set to be detected at Low level.

(4) Address modes

Dual-address mode is the only address mode available for the DMAC in the TMP1942. There is no single-address mode for the DMAC.

In dual-address mode, data transfers are performed between two memory devices or between memory and an I/O device. The addresses of the source and destination devices are output by the DMAC. When accessing an I/O device, the DMAC asserts the DACKn signal. In dual-address mode, the DMAC executes two bus operations, one for reading and one for writing. The transfer data read from the source device is temporarily stored in the DMAC's internal data-holding register (DHR) before being written to the destination device.

(5) Channel operation

The DMAC has four channels (channels 0 to 3). Each channel is activated by setting the start bit (Str) in the channel control register (CCRn) to 1, so that the device enters ready state.

When a transfer request occurs while a channel is in ready state, the DMAC gains control of the bus and performs a data transfer. When there are no more transfer requests, the DMAC finishes control of the bus, thereby entering ready state. When transfer for a channel is completed, the channel is placed in idle state. Transfers may be terminated either normally or abnormally (for example, when an error occurs during transfer). An interrupt signal can be generated on completion of transfer.

Figure 3.8.11 State Transitions for Channel Operations

(6) Summary of transfer mode combinations

The DMAC can perform data transfers as follows according to the combination of mode settings.

Transfer Request	Edge/Level	Address Mode	Transfer Devices
Internal	—	Dual	Memory-to-memory
			Memory-to-memory
External	Low-level	Dual	Memory-to-I/O
			I/O-to-memory

#### (7) Address change

There are essentially three methods for changing the transfer address: increment, decrement or fixed. The method can be set independently for the source and destination addresses using the SAC and DAC bits in the CCRn register. If the transfer device is a memory device, increment, decrement or fixed may be specified. If the transfer device is an I/O device, only fixed may be specified. When an I/O device is selected as the source or destination device, be sure to set the SAC and DAC bits in the CCRn register to "fixed".

If "increment" or "decrement" is selected as the address change method, the bit position at which counting begins can be set using the SACM and DACM bits in the DTCRn register. SACM corresponds to the source address and DACM the destination address. The bit position at which counting the address begins can be specified as bit 0, 4, 8, 12 or 16. Selecting bit 0 results in normal increment or decrement, increment or irregular decrement.

Examples of how the address changes are shown below.

# Example 1: When regular increment is selected for the source device and irregular increment is selected for the destination device

SAC:	Increment	the address
DAC:	Increment	the address
TrSiz:	Transfer ir	n units of 32 bits
Source addres	s: 0xA000_1	000
Destination ad	ldress: 0xB000_0	000
SACM = 000:	Count the	address beginning at bit 0 of the address counter
DACM = 001:	Count the	address beginning at bit 4 of the address counter
	Source	Destination
First time	0xA000_1000	0xB000_0000

Fourth time

#### 3.8.4.2 Transfer requests

For data to be transferred by the DMAC, a transfer request must be generated and transmitted to the DMAC. There are two types of DMAC transfer requests: internal transfer requests and external transfer requests. The transfer request type can be set individually for each channel.

For either type of transfer request, when a transfer request occurs after channel operation has been activated, the DMAC will gain control of the bus and perform data transfer.

• Internal transfer requests

A transfer request can be generated immediately by setting the Str bit in the CCRn register to 1 while the ExR bit in the same register = 0. This transfer request is referred to as an internal transfer request.

In the case of an internal transfer request, because the transfer request remains active until channel operation has been completed, data transfers will be performed successively unless transition to a higher priority channel occurs or until bus control is transferred to a higher priority bus master.

Internal transfer requests can only be used for transfers between memory and memory.

• External transfer requests

A transfer request is generated when the interrupt controller is notified of a transfer request by the assertion of the INTDREQn signal for a channel after the channel has been placed in ready state by setting the Str bit of the CCRn register to 1 while the ExR bit in the CCRn register = 0. This transfer request is referred to as an external transfer request. External transfer requests can be used for transfers between two memory devices and between memory and an I/O device.

Assertion of the INTDREQn signal is recognized by detecting an edge or a level. The active edge or level is specified using the PosE bit in the CCRn register. However, because the INTDREQn signal in the TMP1942 is low-active, always make sure that the signal is set to be detected at Low level.

The amount of data to be transferred for one transfer request is specified using the TrSiz field in the CCRn register. This can be specified as 32 bits, 16 bits or 8 bits.

Transfer requests from the interrupt controller are cleared by assertion of the DACKn signal. The DACKn signal is asserted only when the number of bytes to be transferred during an I/O device bus cycle or a memory-to-memory transfer (as specified by the value of the BCRn register) falls to 0. Consequently, for data transfer between memory and an I/O device INTDREQn is cancelled every transfer request with the result that only one transfer is performed for the amount of data specified by TrSiz. On the other hand, in memory-to-memory transfers, INTDREQn is not cancelled until the number of bytes to be transferred (as specified by the value of the BCRn register) falls to 0; hence several data transfers can be performed successively by a single transfer request.

Note that if an interrupt of the type specified for INTDREQn is acknowledged by the DMAC, but the interrupt is cleared by the interrupt controller or by another device before the DMAC starts the DMA transfer, one DMA transfer may be performed after the interrupt has been cleared.

# TOSHIBA

## 3.8.4.3 Address modes

The TMP1942 only supports dual-address mode in which both the source and destination devices are explicitly addressed..

In dual-address mode the DMAC first executes a read from the source device. The data read from the source device is temporarily stored in the DMAC' s internal register DHR. Next, the DMAC executes a write to the destination device to write this data to the destination device, thus performing a data transfer from the source to the destination device.

Although bit 15 of the CCRn register in the TMP1942 can be used to specify the address mode, this bit must always be set to 0 because the TMP1942 only supports dual-address mode.

Figure 3.8.12 Diagram of Data Transfer in Dual-Address Mode

Figure 3.8.13 Diagram of Data Transfer in Single-Address Mode

Dual-address mode

In dual-address mode, a data transfer is executed using two bus operations:

- -Read operation, in which the DMAC outputs the address of the source device, reads data from the source device and stores the data in its internal register DHR
- -Write operation, in which the DMAC outputs the address of the destination device and writes the stored data from DHR to the destination device

In dual-address mode, three types of transfers can be performed:

- -Memory-to-memory
- -Memory-to-I/O device
- -I/O device-to-memory

The units of data transfer performed by the DMAC are equal to the amount of data (32 bits, 16 bits or 8 bits) specified in the TrSiz field of the CCRn register. This amount of data is transferred each time a transfer request is recognized.

In dual-address mode, an amount of data equal to the transfer unit is read from the source device into the DHR register, then the data is written from the DHR register to the destination device.

Memory accesses occur at intervals equal to the unit of data transfer which has been set. When external memory is accessed, if the transfer unit is 32 bits and the bus width set by the CS/wait controller is 16 bits, then two 16-bit accesses will occur. Similarly, if the transfer unit is 32 bits and the bus width set by the CS/wait controller is 8 bits, then four 8-bit accesses will occur. For memory-to-I/O device or I/O device-to-memory data transfers, the bus width of the I/O device (the device port size) needs to be set (to 32 bits, 16 bits or 8 bits) using the DPS field in the CCRn register, in addition to the unit of data transfer.

If the unit of data transfer and the device port size are equal, the DMAC will perform one read or write operation for the I/O device.

If the device port size is smaller than the unit of data transfer, the DMAC will perform multiple read or write operations for the I/O device. For example, when performing a transfer to memory from an I/O device whose device port size is 8 bits when the unit of data transfer is 32 bits, the DMAC will read data from the I/O device and store it in the DHR register four times, 8 bits at a time, and then write 32 bits of data from the DHR register to memory in one operation (or in two operations if the external memory' s data bus is 16 bits wide).

The source and destination addresses change at intervals equal to the unit of data transfer. The value of the BCRn register also changes by an amount equal to the unit of data transfer. The device port size cannot be set to a value greater than the unit of data transfer. Table 3.8.2 summarizes the above information:

TrSiz	DPS	Number of Bus Operations Performed on I/O Device
0x (32 bits)	0x (32 bits)	Once
0x (32 bits)	10 (16 bits)	Twice
0x (32 bits)	11 (8 bits)	Four times
10 (16 bits)	0x (32 bits)	Setting prohibited
10 (16 bits)	10 (16 bits)	Once
10 (16 bits)	11 (8 bits)	Twice
11 (8 bits)	0x (32 bits)	Setting prohibited
11 (8 bits)	10 (16 bits)	Setting prohibited
11 (8 bits)	11 (8 bits)	Once

Table 3.8.2 Unit of Data Transfer and Device Port Size (Dual-Address Mode)

Note: The DMAC does not increment or decrement the address for I/O peripherals. Therefore, if, for example, TrSiz is programmed to 16 bits and DPS is programmed to 8 bits, both the first and second bus cycles access the lower eight bits of the I/O data bus.

#### 3.8.4.4 Channel operations

A channel is activated when the Str bit in the CCRn register for the channel is set to 1. When a channel is activated, it is checked for errors; if no error is found, it is placed in ready state.

If a transfer request occurs while a channel is in ready state, the DMAC gains control of the bus and starts a transfer operation.

Channel operation may terminate normally or abnormally, for example, when operation is forcibly terminated or terminated by an error. This status is indicated by the CSRn register.

(1) Starting channel operation

A channel is activated when the Str bit in the CCRn register for the channel is set to 1.

When a channel is activated, it is checked for a configuration error; if no error is found, it is placed in ready state. If an error is detected, the channel operation terminates abnormally. When a channel is placed in ready state, the Act bit in the CSRn register for the channel is set to 1.

If internal transfer requests have been set for the channel, a transfer request will be generated immediately, upon which the DMAC will gain control of the bus and start a data transfer. If external transfer requests have been set for the channel, a transfer request will be generated by assertion of INTDREQn, upon which the DMAC will gain control of the bus and start a data transfer.

(2) Terminating channel operation

Channel operation may terminate either normally or abnormally. This status is indicated in the CSRn register.

If an attempt is made to set the Str bit in the CCRn register to 1 while the NC bit or AbC bit of the CSRn register = 1, channel operation will not start and will terminate abnormally.

#### Normal termination

Channel operation terminates normally in the following case. Note that, in this case, transfer will always terminate after the DMAC has finished transferring an amount of data equal to the unit of data transfer (the value set in the TrSiz field of the CCRn register).

When data transfer has been completed after the value of the BCRn register has fallen to 0

#### Abnormal termination

Data transfers by the DMAC may terminate abnormally in the following cases:

• Termination due to configuration errors

A configuration error is an error in the DMA transfer settings. Since a configuration error occurs before the DMAC starts data transfer operation, the SARn, DARn and BCRn register values will remain as set. When operation for a channel terminates abnormally due to a configuration error, the Conf bit in the CSRn register is set to 1 at the same time that the AbC bit is set to 1. Causes of configuration errors are shown below.

-Both SIO and DIO are set to 1.

-The CCRn Str bit is set to 1 when the NC bit or AbC bit in the CSRn register = 1.

- -A value which cannot be divided by the unit of data transfer is set in the BCRn register.
- -Values which cannot be divided by the unit of data transfer are set in the SARn and DARn registers.
- -An illegal combination of the device port size and data transfer unit has been set.
- -The Str bit in the CCRn register is set to 1 while the BCRn register = 0.
- Termination due to bus errors

When transfer terminates abnormally due to a bus error, the BES or BED bit in the CSRn register is set to 1 at the same time that the AbC bit in the CSRn register is set to 1.

-The CPU is notified that a bus error has occurred during data transfer.

#### 3.8.4.5 Channel priority

The DMAC has four channels. A channel with a lower channel number always has higher priority. Therefore, if transfer requests occur for channels 0 and 1 simultaneously, the DMAC will perform the transfer operation for channel 0' s transfer request first. When there are no more transfer requests for channel 0, if the transfer request for channel 1 is still in effect, the DMAC will perform the transfer operation on channel 1. (For internal transfer requests, the transfer request is held unless it is cleared. For external transfer requests by the interrupt controller. If the active state is set to edge mode, the transfer request will be held by the interrupt controller. However, if the active state is set to level mode, the interrupt controller will not hold the transfer request. Therefore, if level mode is set, the interrupt request signal must be kept asserted until it is recognized by the DMAC.)

If a transfer request for channel 0 occurs while data transfer on channel 1 is under way, a channel transition will occur. The data transfer on channel 1 will be suspended and the DMAC will start transfer on channel 0. When there are no more transfer request for channel 0, the DMAC will resumes the transfer operation on channel 1.

Channel transition occurs when the DMAC has finished transferring an amount of data equal to the unit of data transfer. In dual-address mode, this is when the DMAC has finished writing all the stored data from the DHR register to the destination device.

#### 3.8.4.6 Interrupts

The DMAC can generate an interrupt request to the TX19 processor core on completion of channel operation. There are two types of interrupts which can be requested in this case: normal completion interrupt and abnormal completion interrupt.

Normal completion interrupt

When channel operation terminates normally, the NC bit in the CSRn register is set to 1. At this time, if normal completion interrupts have been enabled using the NIEn bit in the CCRn register, an interrupt request to the TX19 processor core is generated.

• Abnormal completion interrupt

When channel operation terminates abnormally, the AbC bit in the CSRn register is set to 1. At this time, if abnormal completion interrupts have been enabled by the AbIEn bit in the CCRn register, an interrupt request to the TX19 processor core is generated.

### 3.8.4.7 Endian mode

If the unit of data transfer and the device port size are not equal in dual-address mode, the DMAC will assemble or disassemble data in the DHR register.

For example, if the source device is an I/O device whose port size is 8 bits while the destination device is a memory device, and the unit of data transfer is 32 bits, the DMAC reads data from the I/O device four times and assembles it into 32 bits of data in the DHR register before writing it to memory.

For example, the diagram below shows the relationship between an 8-bit I/O device and a 32-bit DHR register.

The TMP1942 supports only little-endian data alignment.

Figure 3.8.14 Data Packing and Unpacking

#### 3.8.5 Operation

DMAC operations are synchronized to the rising edges of SYSCLK.

- 3.8.5.1 Dual-address mode
  - Memory-to-memory transfer

Figure 3.8.15 shows a timing example for one transfer session when 16-bit data is being transferred from external memory (which is 16 bits wide) to external memory (which is also 16 bits wide). Although it is not shown here, data is transferred successively until the value of the BCRn register falls to 0.

Figure 3.8.15 Dual-Address Mode (Memory to Memory)

Memory-to-I/O device transfer

Figure 3.8.16 shows a timing example for memory-to-I/O device transfer for cases where the unit of data transfer and the device port size are set to 16 bits and 8 bits, respectively.

• I/O device-to-memory transfer

Figure 3.8.17 shows a timing example for I/O device-to-memory transfer for cases where the unit of data transfer and the device port size are set to 16 bits and 8 bits, respectively.

Figure 3.8.17 Dual-Address Mode (I/O Device to Memory)

Example: DMA transfer of serially received data (SCnBUF) to internal RAM

Example DMA settings

- Channel used: 0
- Source address: SC1BUF
- Destination: 0xFFFF\_9800 (physical address)
- Number of bytes transferred: 256

Example serial channel settings

- Data length: 8 bits, UART
- Serial channel: Channel 1
- Transfer rate: 9600 bps

DMA (channel 0) is used for transfer. DMA0 is activated by an interrupt received on SIO1.

# 3.9 8-Bit Timers (TMRA)

The TMP1942 contains twelve 8-bit timer channels (TMRA0-TMRAB).

There are six TMRA modules, referred to as TMRA01, TMRA23, TMRA45, TMRA67, TMRA89 and TMRAAB, each of which is comprised of two channels. Each module can operate in the following four modes:

- 8-bit interval timer mode
- 16-bit interval timer mode
- 8-bit programmable square wave output mode (PPG: variable duty with variable cycle)
- 8-bit pulse width modulation output mode (PWM: variable duty with constant cycle)

Figure 3.9.1 shows a block diagram of TMRA01. Each channel consists primarily of an 8-bit up-counter, an 8-bit comparator and an 8-bit timer register. Each pair of channels also incorporates one prescaler and one timer flip-flop. Timer operation modes and flip-flops are controlled by five registers.

The six modules (TMRA01, TMRA23, TMRA45, TMRA67, TMRA89 and TMRAAB) operate independently of each other. Because each module functions the same way except for a few differences as shown in Tables Table 3.9.1 and Table 3.9.2, operation of the TMRA01 only is described here.

Specification -		Module

### 3.9.1 Block diagram of each module

Only a block diagram of TMRA01 is described here. It applies to all other modules with the exception of differences in register, signal and other element names.

Figure 3.9.1 TMRA01 Block D iagram

### 3.9.2 Functional description of each circuit

#### (1) Prescaler

The TMP1942 has a 9-bit prescaler to supply a clock to TMRA01. The prescaler's input clock  $\phi$ T0 has a frequency of fperiph, fperiph/2 or fperiph/4 as selected by SYSCR0<PRCK1:PRCK0> in the CG block.

fperiph is either the clock fgear as selected by SYSCR1<FPSEL> in the CG block or the clock fc before division by the clock gear.

The prescaler is set to either run or stop by TA01RUN<TA0PRUN>. Writing a 1 to this bit causes the prescaler to start counting and writing 0 causes it to clear itself and stop counting. Table 3.9.3 shows the resolutions of the prescaler output clocks.

						@fc = 32 MHz
Peripheral	Clock Gear	Selected	Pre	escaler Output	Clock Resolu	tion
Clock Selection <fpsel></fpsel>	Value <gear1:0></gear1:0>	Prescaler Clock <prck1:0></prck1:0>	φT1	φ <b>T</b> 4	φT16	φT256

#### Table 3.9.3 Prescaler Output Clock Resolutions

Note 1: The prescaler's output clock  $\phi$ Tn must be selected such that the relationship  $\phi$ Tn < fsys/2 is satisfied (i.e.,  $\phi$ Tn must be slower than fsys/2).

Note 2: Do not change the clock gear value while the timer is operating.

Note 3: The - character meams "Don't use".

#### (2) Up-counters (UC0 and UC1)

UC0 and UC1 are 8-bit binary counters which count up synchronously with the input clock selected in timer mode register TA01MOD.

The input clock for UC0 is either the external clock entered via the TA0IN pin or one of the three prescaler output clocks,  $\phi$ T1,  $\phi$ T4 or  $\phi$ T16, according to the value set in TA01MOD <TA0CLK1: TA0CLK0>.

The input clock for UC1 varies with the operating mode. In 16-bit timer mode, up-counter UC0's overflow output is the input clock for UC1; in any other mode, the input clock for UC1 is either one of the three prescaler output clocks,  $\phi$ T1,  $\phi$ T16 or  $\phi$ T256, or the comparator output (match detection) from TMRA0, as determined by the value set in TA01MOD<TA1CLK1:TA1CLK0>.

The TA01RUN<TA0RUN> and <TA1RUN> bits set the up-counters to run or stop. When reset, the up-counters are cleared with the timers stopped.

#### (3) Timer registers (TA0REG and TA1REG)

TAOREG and TA1REG are 8-bit registers used to set interval times. When the value set in one of these timer registers matches the corresponding up-counter value, the comparator's match detection signal becomes active. If the value set is 00H, this signal will become active when the up-counter overflows.

TAOREG is paired with a register buffer to form a dual-buffer structure. The double-buffer is controlled by the setting of TA01RUN<TA0RDE>. The double-buffer is disabled when <TA0RDE> = 0 and enabled when <TA0RDE> = 1.

When the double-buffer is enabled, data transfer from the register buffer to the timer register is initiated by a  $2^{n}$ -1 overflow in PWM mode or by cycle match detection in PPG mode. The double-buffer cannot be used in timer mode.

When reset, <TA0RDE> is initialized to 0, disabling the double-buffer. To use the double-buffer, write data in the timer register and set <TA0RDE> to 1, then write the following data in the register buffer.

Figure 3.9.2 shows the structure of TAOREG.

Figure 3.9.2 Structure of Timer Register 0 (TA0REG)

When data is written to TAOREG, the same address is allocated to the timer register and the register buffer.
 When <TAORDE> = 0, the same value is written to the timer register and the register buffer.
 When <TAORDE> = 1, data is written only to the register buffer.

The addresses of the individual timer registers are as follows:

TA0REG: 0xFFFF_F102H	TA1REG: 0xFFFF_F103H
TA2REG: 0xFFFF_F10AH	TA3REG: 0xFFFF_F10BH

Each register is a write-only register and cannot be read.

(4) Comparator (CP0)

This circuit compares the up-counter value with the timer register value. When the values match, it clears the up-counter to 0 and at the same time generates an INTTA0 or INTTA1 interrupt. Also, if timer flip-flop inversion is enabled, it inverts the timer flip-flop value.

(5) Timer flip-flop (TA1FF)

The timer flip-flop TA1FF is designed to be inverted by a match detection signal from the comparator. Inversion can be disabled or enabled by setting TA1FFCR<TAFF1IE>.

TA1FF is cleared to 0 by a reset. The TA1FF value can be set to 1 or 0 by writing 01 or 10 to TA1FFCR<TAFF1C1:TAFFCR0>. Also, the TA1FF value can be inverted by writing 00 to these bits (this is known as a soft inversion).

The TA1FF value can be forwarded to the timer flip-flop output pin, TA1OUT (shared with PA6). When timer output is needed, this pin must be set for that purpose by using the port A registers PACR and PAFC.

Selects the signal which inverts timer flip-flop B (TABFF).

(Don't care unless in 8-bit timer mode)
---

0	Inverted by TMRAA
1	Inverted by TMRAB

TABFFCR bits 4, 5, 6 and 7 are undefined when read. Note:

Figure 3.9.14 TMRA Registers

## 3.9.4 Functional description for each mode

(1) 8-bit timer mode

TMRA0 and TMRA1 can be used as 8-bit interval timers independently of each other. You must stop TMRA0 and TMRA1 before attempting to set their functions or count data.

a. Generating interrupts periodically

The following description uses TMRA1 as an example. To generate a TRAM1 interrupt, INTTA1, at certain intervals, first stop timer 1 and set the operating mode, input clock and cycle in the TA01MOD and TA1REG registers. Ne×t, enable the INTTA1 interrupt and start timer 1.

Example: To generate INTTA1 interrupts every 20  $\mu$ s with fc = 32 MHz, set the registers in the following sequence:

		*CI	ock	cond	ditior	IS			em clock: scaler clock	High-speed (fc) : fperiph/4 (fperiph = fsys)
		Ν	1SB				LS	в		
_		7	6	5	4	3	2	1	0	
TA01RUN	←	_	-	Х	Х	-	_	0	-	Stop TMRA1 and clear it to 0.
TA01MOD	←	0	0	Х	Х	1	0	Х	X	Select 8-bit timer mode and set input clock to $\phi$ T1 (0.25 $\mu$ s resolution, fc = 32 MHz).
TA1REG	←	0	1	0	1	0	0	0	0	Write 20 $\mu$ s/ $\phi$ T1 = 80 (50H) to TA1REG.
IMC5LH	←	X	Х	1	1	0	1	0	1	Enable INTTA1 and set interrupt level = 5 and rising edge detection.
TA01RUN	←	-	Х	Х	Х	-	1	1	-	Start TMRA1.

Note: X = Don't care; "—" = No change

For a description of input clock selection, refer to Table 3.9.3.

Note: The input clocks for TMRA0 and TMRA1 differ as shown below. TMRA0: TA0IN pin input, φT1, φT4 or φT16 TMRA1: TMRA0 match detection signal, φT1, φT16 or φT256 b. Outputting a 50% duty cycle square wave

Invert the value of timer flip-flop TA1FF at certain intervals and forward the inverted value to the timer flip-flop output pin, TA1OUT.

Example: To output a 1.5- $\mu$ s cycle square wave with fc = 32 MHz on the TA1OUT pin, set each register in the following sequence. In this example TMRA1 is used to show how to set the registers, although either TMRA0 or TMRA1 may be used.

Figure 3.9.15 Square Wave Output Timing (50% Duty Cycle)

c. Using a match signal from TMRA0 to make TMRA1 count

Select 8-bit timer mode and set the TMRA1 input clock to the TMRA0 comparator output.

#### (2) 16-bit timer mode

TMRA0 and TMRA1 can be used together as a 16-bit interval timer. To select 16-bit timer mode, set TA01MOD<TA01M1:TA01M0> to 01.

In 16-bit timer mode, the TMRA1 input clock is derived from the TMRA0 overflow output regardless of the TA01MOD<TA1CLK1:TA1CLK0> settings. For a description of TMRA1 input clock selection, refer to Table 3.9.3.

Set the timer interrupt cycle in the timer registers TA0REG and TA1REG by writing the eight low-order bits to TA0REG and the eight high-order bits to TA1REG. Always set TA0REG first. This is because compare operation is temporarily disabled when data is written to TA0REG; it is re-enabled when data is subsequently written to TA1REG.

Example: To generate INTTA1 interrupts every 0.2 second with fc = 32 MHz, set the values shown below in the timer registers TA0REG and TA1REG.

*Clock conditions	System clock:	High-speed (fc)
	High-speed clock gear:	× 1 (fc)
	Prescaler clock:	fperiph/4 (fperiph = fsys)

With  $\phi$ T16 (= 4.0 µs at 32 MHz) used as the input clock,

 $0.2 \text{ s/4.0 } \mu \text{s} = 50000 = \text{C350H}$ 

Therefore, TA1REG must be set to 03H and TA0REG to 50H.

A TMRA0 comparator output is generated each time the up-counter UC0 and timer register TA0REG match (the up-counter UC0 is not cleared). In this case INTTA0 is not generated.

The TMRA1 comparator outputs a match detection signal at each comparator timing when the up-counter UC1 and timer register TA1REG match. If the comparators in both TMRA0 and TMRA1 output a match detection signal at the same time, the up-counters UC0 and UC1 will be cleared to 0 and an INTTA1 interrupt is generated. Also, if inversion is enabled, the value of timer flip-flop TA1FF will be inverted.

E×ample: TA1REG = 04H and TA0REG = 80H

Up-counter values (UC1 and UC0)	0000H	0080H	0180H	0280H	0380H	0480H	
Match detection signal from TMRA0 comparator							
Interrupt INTTA1						h	
Timer output TA1OUT	_					) Inv	vert

Figure 3.9.17 Timer Output in 16-Bit Timer Mode

(3) 8-bit PPG (programmable square wave) output mode

A square wave of any frequency with any duty cycle can be output using TMRA0. Either Low-active or High-active output pulses can be selected.

TMRA1 cannot be used in this mode. The square wave is forwarded to TA1OUT (shared with PA6).

Figure 3.9.18 8-Bit PPG Output Waveform

This mode is used to output a programmable square wave by inverting the timer output every time the 8-bit up-counter UC0 matches the timer registers TA0REG and TA1REG.

However, the condition (TA0REG set value) < (TA1REG set value) must be satisfied. Although the up-counter UC1 of TMRA1 cannot be used in this mode, TA01RUN<TA1RUN> must be set to 1 to enable TMRA1 counting.

Figure 3.9.19 shows a block diagram of 8-bit PPG output mode.

Figure 3.9.19 8-Bit PPG Output Mode Block Diagram

If TAOREG has its double-buffer enabled in this mode, the value in the register buffer is shifted into TAOREG when TA1REG and UC0 match.

If it is necessary to change the duty cycle, using the double-buffer facilitates satisfying the requirements for small duty cycle waveforms.

Figure 3.9.20 Register Buffer Operation

Example: To output a 1/4 duty cycle 50-kHz pulse (fc = 32 MHz)

Calculate the values to be set in the timer registers as follows:

To obtain a frequency of 50 kHz, generate a waveform with a period t = 1/50 kHz = 20 µs. When  $\phi T1 = 0.25$  µs (at fc = 32 MHz),

 $20 \ \mu s / 0.25 \ \mu s = 80$ 

Therefore, TA1REG must be set to 80 (= 50H).

Ne×t, to obtain a 1/4 duty cycle, using the formula t  $\times$  1/4 = 20  $\mu$ s  $\times$  1/4 = 5  $\mu$ s,

 $5 \ \mu s / 0.25 \ \mu s = 20$ 

Therefore, TA0REG must be set to 20 (= 14H).

Note: X = Don't care; "-" = No change

# TOSHIBA

### (4) 8-bit PWM output mode

This mode, only available for TMRA0, can output PWM pulses with up to 8-bit resolution. PWM output is forwarded to the TA1OUT pin (shared with PA6).

In this mode TMRA1 can be used as an 8-bit timer.

Timer output is inverted when the up-counter UC0 and the value set in the timer register TA0REG match. It is also inverted when a  $2^{n}$ -1 counter overflow occurs (n = 6, 7 or 8 as specified in TA01MOD<PWM01:PWM00>). The up-counter UC0 is cleared to 0 upon the occurrence of a  $2^{n}$ -1 counter overflow.

Before PWM mode can be used, the following conditions must be satisfied:

(TA0REG set value)  $< (2^{n}-1 \text{ counter overflow set value})$ 

(TAOREG set value)  $\neq 0$ 

Figure 3.9.21 8-Bit PWM Output Waveform

Figure 3.9.22 shows a block diagram of 8-bit PWM output mode.

Figure 3.9.22 8-Bit PWM Output Mode Block Diagram

If TAOREG has its double-buffer enabled in this mode, the value in the register buffer is shifted into TAOREG upon the detection of a  $2^{n}$ -1 overflow. Using the double-buffer facilitates satisfying the requirements for small duty cycle waveforms.

Figure 3.9.23 Register Buffer Operation

E×ample: To output the following PWM waveform on the TA1OUT pin using TMRA0 when fc = 32 MHz

To achieve a PWM cycle of 31.75  $\mu s$  with  $\phi T1$  = 0.25  $\mu s$  (at fc = 32 MHz), the following equation must be satisfied:

 $31.75 \ \mu s/0.25 \ \mu s = 127 = 2^{n}-1$ 

Therefore, n must be set to 7.

Since the Low-level period is 18  $\mu$ s and  $\phi$ T1 = 0.25  $\mu$ s,

 $18 \ \mu s / 0.25 \ \mu s = 72 = 48 H$ 

Therefore, TAOREG must be set to 48H.

Table 3.9.5	Register	Settings	for Each	Timer Mode
-------------	----------	----------	----------	------------

"-" = Don't care

Note: In 8-bit PWM generation mode, the UC1 can be used as an 8-bit timer. However, the match-detect output from the UC0 can not be used as a clock source for the UC1, and the timer output is not available for the UC1.

## 3.10 16-Bit Timers/Event Counters (TMRBn)

The TMP1942 contains fourteen multi-function 16-bit timer/event counter channels (TMRB0-TMRBD). TMRBn can operate in the following four modes:

- 16-bit interval timer mode
- 16-bit event counter mode
- 16-bit programmable square wave output (PPG) mode
- 2-phase pulse input counter mode (only for TMRB2 and TMRB3)

In addition, when used in combination with the capture function, TMRBn can be run in the following modes:

- Frequency measurement mode
- Pulse width measurement mode
- Time difference measurement mode

Each channel consists primarily of a 16-bit up-counter, two 16-bit timer registers (one with a double-buffer structure), two 16-bit capture registers, two comparators, capture input controller, and a timer flip-flop with accompanying control circuit. Timer operating modes and flip-flops are controlled by eleven registers.

All channels TMRB0 to TMRBD operate independently of each other. Because each channel functions the same way except for the 2-phase pulse counter function and a few other differences as shown in Tables 3.10.1 to 3.10.2, operation of the TMRB0 only is described here, with an explanation of the 2-phase pulse counter function for TMRB2 and TMRB3.

## 3.10.2 Function description of each circuit

(1) Prescaler

The TMP1942 has a 5-bit prescaler to supply a clock to TMRB0. The prescaler's input clock  $\phi$ T0 has a frequency of fperiph, fperiph/2, or fperiph/4 as selected by SYSCR0<PRCK1:PRCK0> in the CG block.

Fperiph is either the clock fgear as selected by SYSCR1<FPSEL> in the CG block or the clock fc before division by the clock gear.

The prescaler is set to either run or stop by TA01RUN<TA0PRUN>. Writing a 1 to this bit causes the prescaler to start counting and writing 0 causes it to clear itself and stop counting. Table 3.10.5 shows the resolutions of the prescaler output clocks.

	1				@fc = 32 MHz
Peripheral	Clock Gear Value	Selected	Prescaler	Output Clock R	Resolution
Clock Selection <fpsel></fpsel>	<gear1:0></gear1:0>	Prescaler Clock <prck1:0></prck1:0>	φT1	φΤ4	φT16

		10 (fperip)			fc/2 <sup>5</sup> (1.0 μs)

Table 3.10.5 Prescaler Output Clock Resolutions

Note 1: The prescaler's output clock  $\phi$ Tn must be selected such that the relationship  $\phi$ Tn < fsys/2 is satisfied (i.e.,  $\phi$ Tn must be slower than fsys/2).

Note 2: Do not change the clock gear value while the timer is running.

Note 3: The — character means "Don't use".

#### (2) Up-counter (UC0)

UC0 is a 16-bit binary counter which counts up synchronously with the input clock selected by TB0MOD<TB0CLK1:TB0CLK0>.

The input clock for UC0 is either the external clock entered via the TB0IN0 pin or one of the three prescaler output clocks,  $\phi$ T1,  $\phi$ T4 or  $\phi$ T16. The setting of TB0RUN<TB0RUN> either causes the up-counter UC0 to count, or stops and clears it. If the value in the up-counter UC0 matches the value in the timer register TB0RG1H/L while clearing is enabled, UC0 is cleared to 0. Clearing of UC0 can be enabled or disabled by setting TB0MOD<TB0CLE> accordingly.

If clearing is disabled, the counter functions as a free-running counter. In addition, when UC0 overflows, it generates an overflow interrupt INTTB01.

TMRB2 and TMRB3 support the 2-phase pulse input counter feature. When 2-phase pulse counter mode is selected with the setting of TB2RUN<TB2UDCE>, UC0 functions as an up/down-counter with an initial value of 0x7FFF. When the counter overflows, it is reloaded with an initial value of 0x0000. When the counter underflows, it is reloaded with an initial value of 0xFFFF. UC0 only functions as an up-counter in other modes.

Note: Programming the TB0CLK[1:0] and TB0CLE bits in the TB0MOD register should only be attempted when the timer is not running.

(3) Timer registers (TB0RG0H/L and TB0RG1H/L)

Each channel incorporates two 16-bit registers used to set a counter value. When the value set in one of these timer registers matches the value of up-counter UC0, the comparator's match detection signal becomes active.

Timer registers TB0RG0H/L and TB0RG1H/L can be written in a single operation using a 2-byte data transfer instruction, or in two operations (the eight low-order bits first and then the eight high-order bits) using a 1-byte data transfer instruction.

The timer register TB0RG0 has a double-buffer structure, being paired with register buffer 0. The setting of TB0RUN<TB0RDE> enables or disables the register's double-buffer facility. The double-buffer is disabled when  $\langle TB0RDE \rangle = 0$  and enabled when  $\langle TB0RDE \rangle = 1$ . When the double-buffer is enabled, data transfer from register buffer 0 to the timer register TB0RG0 is initiated by a match of UC0 and TB0RG1.

When reset, the contents of the timer registers TB0RG0 and TB0RG1 are undefined; hence, data must be written to the timer registers before the 16-bit timers can be used. A reset initializes TB0RUN<TB0RDE> to 0, disabling the double-buffer. To use the double-buffer, write data to the timer registers and set <TB0RDE> to 1, then write the following data in the register buffer.

TBORGO and its register buffer both have the same addresses,  $0xFFFF_F188$  and  $0xFFFF_F189$ , allocated to them. When  $\langle TBORDE \rangle = 0$ , the same value is written to TBORGO and its register buffer; when  $\langle TBORDE \rangle = 1$ , the value is only written to the register buffer. Therefore, the register buffer must be disabled before the initial value is written to the timer register.

Note: Programming the TBORDE bit should only be attempted when the timer is not running.

#### (4) Capture registers (TB0CP0H/L and TB0CP1H/L)

TB0CP0H/L and TB0CP1H/L are 16-bit registers used to latch the value of the up-counter UC0. Data may be read out from a capture register in a single operation using a 2-byte data transfer instruction, or in two operations (the eight low-order bits first and then the eight high-order bits) using a 1-byte data transfer instruction.

#### (5) Capture controller

This circuit controls the timing at which the value in the up-counter UC0 is latched into the capture registers (TB0CP0 and TB0CP1). The capture register latch timing is set using TB0MOD<TB0CMPM1:TB0CMPM0>.

In addition, the value of the up-counter UC0 can be latched into the capture registers by software. Each time TB0MOD<TB0CP0> is set to 0, the UC0 value at that point is latched into TB0CP0. Before this function can be used, the prescaler must be placed in the Run state by setting TB0RUN<TB0PRUN> to 1.

In 2-phase pulse counter mode (only for TMRB2 and TMRB3), the counter value is latched by software capture.

- Note1: Reading the eight low-order bits of the capture register disables capture operation. Subsequently reading the eight high-order bits of the capture register enables capture operation.
- Note2: If the timer is stopped when only the eight low-order bits have been read, capture operation is not enabled even after the timer is restarted. Do not stop the timer until both the eight low-order and eight high-order bits are read.
- Note3: When the TB0IN0 pin is selected as a capture trigger input, it can not function as a timer clock.
  - (6) Comparators (CP0 and CP1)

The two 16-bit comparators compare the value of the up-counter UC0 with the values set in the timer registers TB0RG0 and TB0RG1 to detect a match. If the value in either TB0RG0 or TB0RG1 matches the value in UC0, the corresponding comparator generates an INTTB0 interrupt.

(7) Timer flip-flop (TB0FF0)

The timer flip-flop TB0FF0 is designed to be inverted by a match detection signal from the comparator or by a latch signal to the capture registers. Inversion can be enabled or disabled by setting TB0FFCR<TB0C1T1,TB0C0T1,TB0E1T1,TB0E0T1> accordingly.

When reset, the TB0FF0 value is undefined. Writing 00 to TB0FFCR<TB0FF0C1:TB0FF0C0> inverts the value of the flip-flop; writing 01 to TB0FFCR<TB0FF0C1,TB0FF0C0> sets the flip-flop to 1; writing 10 to TB0FFCR<TB0FF0C1,TB0FF0C0> clears the flip-flop to 0.

The TB0FF0 value can be forwarded to the timer output pin, TB0OUT (shared with PA2). When timer output is needed, this pin must be set for that purpose by using the port A registers PACR and PAFC.

Note: Programming the TB0FF0C1[1:0] field should only be attempted when the timer is not running.

# 3.10.4 Functional description for each mode

(1) 16-bit interval timer mode

To generate interrupts at certain intervals, set the interval time in the timer register TB0RG1 and enable INTTB01 interrupts.

_		7	б	5	4	3	2	1	0	
TBORUN	←	0	0	Х	Х	-	0	Х	0	Stop TMRB0.
IMC7LH	←	Х	Х	1	1	0	1	0	0	Enable INTTB0 and set its priority level to 4.
TB0FFCR	$\leftarrow$	1	1	0	0	0	0	1	1	Disable trigger.
TB0MOD	←	0	0	1	0	0	1	*	*	Select prescaler output clock as input clock and disable
				( **	' =	01,	10	, 1	1)	capture function.
TB0RG1	←	*	*	*	*	*	*	*	*	Set interval time.
		*	*	*	*	*	*	*	*	(16 bits)
TBORUN	←	0	0	Х	Х	-	1	Х	1	Start TMRB0.

Note: X = Don't care; "-" = No change

(2) 16-bit event counter mode

The timer can be used as an event counter by selecting an external clock (input to the TB0IN0 pin) as its input clock.

The up-counter is incremented on each rising edge of the TB0IN0 pin input. The count value can be read by capturing it by software and reading the captured value.

			7	6	5	4	3	2	1	0		
Γ	TB0RUN	←	0	0	Х	Х	_	0	Х	0	٦	Stop TMRB0.
	PACR	←	_	_	_	-	-	_	_	0	7	Set PA0 to input mode.
	PAFC	←	-	-	-	-	-	-	-	1	J	Set PAO to input mode.
	IMC7LH	←	Х	Х	1	1	0	1	0	0		Enable INTTB0 and set its priority level to 4.
	TBOFFCR	$\leftarrow$	1	1	0	0	0	0	1	1		Disable trigger.
	TB0MOD	←	0	0	1	0	0	1	0	0		Select TB0IN0 pin input as input clock.
	TB0RG1	←	*	*	*	*	*	*	*	*		Set count (16 bits).
	TB0RUN	←	0	0	Х	Х	-	1	Х	1		Start TMRB0.

Note:	X = Don't care; "-" = No change
	When the timer is used as an event counter, the prescaler must be set to run (i.e.
	TB0RUN <tb0prun> must be set to 1).</tb0prun>

(3) 16-bit PPG (programmable square wave) output mode

A square wave of any frequency with any duty cycle (programmable square wave) can be output. Either Low-active or High-active output pulses can be selected.

This mode is used to output a programmable square wave on the TBOOUT pin by triggering inversion of the timer flip-flop (TB0FF) when the values in the up-counter (UC0) and one of the timer registers (TB0RG0 or TB0RG1) match. However, the values set in TB0RG0 and TB0RG1 must satisfy the following condition:

(TB0RG0 set value) < (TB0RG1 set value)

Figure 3.10.30 Example PPG Output Waveform

If TB0RG0 has its double-buffer enabled in this mode, the value in register buffer 0 is shifted into TB0RG0 when TB0RG1 and UC0 match. Using the double-buffer facilitates satisfying the requirements for small duty cycle waveforms.

Figure 3.10.31 Register Buffer Operation

Figure 3.10.32 shows a block diagram of 16-bit PPG output mode.

To use the timer in 16-bit PPG output mode, set each register as shown below.

		7	6	5	4	3	2	1	0	
TBORUN	←	0	0	Х	Х	-	0	Х	0	Disable TB0RG0 double-buffer and stop TMRB0.
TB0RG0	←	*	*	*	*	*	*	*	*	Set duty cycle (16 bits).
TB0RG1	←	*	*	*	*	*	*	*	*	Set PPG cycle (16 bits).
TBORUN	←	1	0	Х	Х	-	0	Х	0	Enable TB0RG0 double-buffer.
										(Duty cycle and PPG cycle are changed by INTTB01 interrupt.)
TBOFFCR	←	Х	Х	0	0	1	1	1	0	Set TB0FF0 so that its value will be inverted on detecting a match with TB0RG0 or TB0RG1. Also initialize TB0FF0 to 0.
TB0MOD	←	0	0	1	0	0	1	*	*	Select prescaler output clock as input clock and disable capture
				( **	· =	01,	10	, 1	1)	function.
P7CR	←	-	1	-	_	-	-	_	_	Set DA2 pip to TROOLT
P7FC	←	_	1	_	_	-	_	_	_	<ul> <li>Set PA2 pin to TB0OUT.</li> </ul>
TBORUN	←	1	0	Х	х	-	1	Х	1	Start TMRB0.

Note1: X = Don't care; "-" = No change Note2: Please do not stop a timer in PPG mode at the time of duty change (please use a double buffer). In order to change a timer-related setup, please perform the following setup, when you resume after a stop (<TBnRUN>="0") (<TBnRUN>="1").

- (1) Change a timer output terminal to a PORT function.
- (2) Timer stop (<TBnRUN>="0")
- (3) Forbid a reversal output at the time of coincidence with a Up Counter and a Timer Register (TBnFFCR<TBnE1T1:TBnE0T1>=00).
- (4) Start a timer (<TBnRUN>="1").
- (5) Suspend a timer (<TBnRUN>="0").
- (6) A setup of the contents of change.
- (7) Change an output terminal from a PORT function to a timer output.
- (8) Start a timer (<TBnRUN>="1").

(4) Application examples using the capture function

With its capture function enabled, TMRB can be used for various applications including those presented in the examples given below:

- a. One-shot pulse output using an external trigger pulse
- b. Frequency measurement
- c. Pulse width measurement
- d. Time difference measurement
- a. One-shot pulse output using an external trigger pulse

To output a one-shot pulse using an external trigger pulse, follow the procedure described below.

Let the 16-bit up-counter UC0 count up in free-running mode using the prescaler output clock. Enter an external trigger pulse via the TB0IN0 pin and use the capture function to latch the up-counter value into the capture register (TB0CP0) at the rising edge of the external trigger pulse.

Set INTC so that an INT3 interrupt is generated when the external trigger pulse goes High. During this interrupt write the sum of the TB0CP0 value (c) and the delay time (d) to the timer register TB0RG0. Similarly, write the sum of the TB0RG0 value and the one-shot pulse width (p), i.e. (c + d + p), to the timer register TB0RG1.

Then, set the relevant field in the timer flip-flop control register (TB0FFCR <TB0E1T1,TB0E0T1>) to 11, enabling the trigger so that the timer flip-flop (TB0FF0) will be inverted on detection of a match between the value of UC0 and the value of TB0RG0 or TB0RG1. After a one-shot pulse is output, disable inversion during INTTB0 interrupt handling.

The terms (c), (d) and (p) in the above explanation correspond to c, d and p in Figure 3.10., One-Shot Pulse Output (with Delay).

# Set-up example: To output a 2 ms one-shot pulse with a delay time of 3 ms after an external trigger pulse on the TB0IN0 pin

		* Clock conditions	System clock:High-speed (fc)High-speed clock gear:× 1 (fc)Prescaler clock:fperiph/4 (fperiph = fsys)
Settings in th	ne main routine		
	765	4 3 2 1 0	Place counter in free-running mode.
<b>-</b>			$\longrightarrow$ Use $\phi$ T1 as clock source for counting.
TB0MOD	$\leftarrow$ X X 1		→ Latch count into TB0CP0 on rise of TB0IN0 input.
TB0FFCR	← X X 0 ∟		$\longrightarrow$ Clear TB0FF0 to 0.
			$\rightarrow$ Disable inversion of TB0FF0.
PACR PAFC	$\leftarrow \rightarrow - \rightarrow$	1	Set PA2 pin to TB0OUT.
IMCOHL	← X X 1	1 0 1 0 0	Enable INT3 and disable INTTB0
IMC7LH	← X X 1	1 0 0 0 0	J
TBORUN	$\leftarrow$ - 0 X	X – 1 X 1	Start TMRB0.
Settings in IN TB0RG0 TB0RG1	← TB0CP0 +	- 3ms/¢T1 - 2ms/¢T1	
TB0FFCR	← X X -	- 1 1 L_J	Enable TB0FF0 inversion when up-counter value matches     TB0BC0 or TB0BC4
IMC7LH	← X X 1	1 0 1 0 0	TB0RG0 or TB0RG1. Enable INTTB0.
Settings in IN	NTTB0		
TB0FFCR	← X X -	- 0 0 L	→ Disable TB0FF0 inversion when up-counter value
_IMC7LH	← X X 1	1 0 0 0 0	matches TB0RG0 or TB0RG1. Disable INTTB0.
Note: X =	Don't care; "-	-" = No change	

If a delay is not necessary, invert TB0FF0 by latching the counter value into TB0CP0; then, during the INT3 interrupt, write the sum of the TB0CP0 value (c) and the one-shot pulse width (p) to TB0RG1. Enable the trigger so that TB0FF0 will be inverted on detection of a match between the value of UC0 and the value of TB0RG1. TB0FF0 inversion should be disabled during INTTB0 interrupt handling.

b. Frequency measurement

With its capture function enabled, the timer can be used to measure the frequency of an external clock.

The frequency is measured using a combination of a 16-bit timer/event counter and 8-bit timers (TMRA01). (TMRA01 determines the measurement time by inverting TA1FF.)

Select TB0IN0 pin input as the count clock for TMRB0 so that it counts up synchronously with the external clock pulses. Set TB0MOD<TB0CPM1:TB0CPM0> to 11. This setting causes the count value of the 16-bit up-counter UC0 to be latched into the capture register TB0CP0 when the 8-bit timer (TMRA01) flip-flop (TA1FF) output goes High, and to be latched into the capture register TB0CP1 when the TA1FF output goes Low.

The frequency is calculated from the difference between the loaded values in TB0CP0 and TB0CP1 based on the measurement time determined by an 8-bit timer interrupt INTTA0 or INTTA1.

Figure 3.10.35 Frequency Measurement

For example, if the 8-bit timers set the High level width of TA1FF to 0.5 s and the difference between TB0CP0 and TB0CP1 is 100, then the frequency is 100/0.5 s = 200 Hz.

## c. Pulse width measurement

With its capture function enabled, the timer can be used to measure the high-level duration of an external pulse. Enter an external pulse via the TB0IN0 pin and let the up-counter (UC0) count up in free-running mode using the prescaler output clock. Then, using the capture function, latch the up-counter value into the capture registers TB0CP0 and TB0CP1 on the rising and falling edges of the external pulse, respectively. Set INTC so that INT5 is generated when the TB0IN0 pin goes Low.

The High-level duration of the pulse can be obtained by finding the difference between TB0CP0 and TB0CP1 and multiplying the resulting value by the internal clock period.

For example, if the difference between TB0CP0 and TB0CP1 is 100 and the prescaler output clock period is 0.5  $\mu$ s, then the pulse width will be  $100 \times 0.5 \ \mu$ s = 50  $\mu$ s.

Additionally, the pulse width which exceeds the UC0 maximum count time specified by the clock source can be measured by software coding.

Figure 3.10.36 Pulse Width Measurement

The Low-level duration can be measured using the time difference measurement function shown in Figure 3.10.. The Low-level duration is obtained by multiplying the difference between the first C2 and the second C1 by the prescaler output clock period during the handling of the second INT5 interrupt.

## d. Time difference measurement

With its capture function enabled, the timer can be used to measure the difference in time between two events. Let the up-counter (UC0) count up in free-running mode using the prescaler output clock. Latch the UC0 value into the capture register TB0CP0 at the rising edge of the pulse input on the TB0IN0 pin. Set INTC so that an INT3 interrupt is generated at that point.

Latch the UC0 value into the capture register (TB0CP1) at the rising edge of the pulse input on the TB0IN1 pin. Set INTC so that an INT4 interrupt is generated at that point.

The difference in time can be obtained by subtracting the value in TB0CP0 from the value in TB0CP1 after the values have been latched into the capture registers, and then multiplying the difference by the internal clock period.

Figure 3.10.37 Time Difference Measurement

(5) 2-phase pulse input counter mode (TMRB2 and TMRB3)

(The function operates in the same way for TMRB2 and TMRB3. Only TMRB2 is described here.)

In this mode, the counter is either incremented or decremented by one according to the state transition of 2-phase clock pulses, with a phase difference of 90 degrees, input from TB2IN0 and TB2IN1. An interrupt is generated when the up/down-counter overflows or underflows, or when it is incremented or decremented.

Function	Double Buffer 0: Disable 1: Enable		Sampling clock selection 0: fs 1: fsys/2	2-phase counter enable 0: Disable 1: Enable	IDLE 0: Idle 1: Operate	Timer Run/Stop Control 0: Stop and cleared 1: Count		

Figure 3.10.40 Register for Setting 2-Phase Pulse Input Counter Mode

Bit 5 of the TB2RUN register (UD2CK) determines the sampling clock to be used. UD2CK (sampling clock selection) = 0: Selects fs (32 kHz) (8 kHz sampling) 1: Selects fsys/2 (fsys/8 Hz sampling)

1) Exiting from STOP mode

Because an 2-phase timer interrupt cannot be used to terminate STOP mode, an interrupt on the INTB or INTC shared pin is used to terminate STOP mode.

The 2-phase counter enters STOP mode while retaining its previous state. Therefore, if the relationship between the state of the input used to terminate STOP mode and the retained state satisfies the condition for counting up or down, the counter value is incremented or decremented after STOP mode has been terminated. (The counter value remains unchanged if the condition is not satisfied.) If it is necessary to obtain a constant counter state after exiting from STOP mode, initialize the 2-phase counter after STOP mode is terminated (clearing TB2RUN<TB2UDCE> to 0 and then setting it to 1 initializes the counter to 0x7FFF).

#### 2) Exiting from SLEEP mode

Because an 2-phase timer interrupt cannot be used to terminate SLEEP mode, an interrupt on the INTBCDE shared pin is used to terminate SLEEP mode. Whether the 2-phase counter is incremented or decremented depends on the state of the input used to terminate SLEEP mode. If it is necessary to obtain a constant counter state after exiting from SLEEP mode, initialize the 2-phase counter after SLEEP mode is terminated (clearing TB2RUN<TB2UDCE> to 0 and then setting it to 1 initializes the counter to 0x7FFF).

#### b. Operating mode

Use appropriate register bits to determine whether the external input signals on the TB2IN0 and TB2IN1 input pins will be sent to the ordinary 16-bit timer or to the up/down-counter.

- In up/down-counter mode, only software capture is available; capture based on external clock timing is not enabled.
- In up/down-counter mode, the comparator is disabled; comparison with timer registers is not performed.

- In up/down-counter mode, ordinary INTB to INTE interrupts (interrupts other than those used to terminate STOP/SLEEP mode) cannot be used.
- The input clock signals are sampled at fs (32 kHz) or based on the high-speed clock (system clock). When fs is used, the maximum input frequency is 8 kHz. When the high-speed clock is used, the maximum input frequency is fsys/8 Hz.

Setting the up/down-counter

Set TB2MOD<TB2CLK0,TB2CLK1> to "00" (prescaler disabled). Next, set bit 4 of the TB2RUN register (TB2UDCE) to determine whether the counter should operate as a up/down counter or as an ordinary up-counter based on external clock input.

TB2UDCE (up/down-counter enable) = 0: Normal 16-bit timer operation 1: Up/down-counter operation

- c. Interrupts
- In NORMAL or SLOW mode

Enable INTTB2 interrupts in the interrupt controller (INTC). An INTTB2 interrupt will occur when the counter either counts up or down. You can determine whether an overflow or underflow has occurred at the same time by reading the status register TB2ST during the handling of the interrupt. An overflow has occurred if TB2ST<INTTBOVF2> = 1. An underflow has occurred if TB2ST<INTTBUDF2> = 1. This register is cleared when read. An overflow causes the counter to be initialized to 0x0000 and an underflow causes the counter to be initialized to 0xFFFF, allowing the counter to continue counting.

Figure 3.10.42 TMRB2 Status Register

## In SLEEP mode

The 2-phase pulse input counter operates. Enable the INTBCDE release input in the clock generator (CG). Use INTnST of the INTBCDE circuit to set the active level for each interrupt input. An up or down counter input generates an INTB or INTC interrupt, causing the counter to exit from SLEEP mode. The interrupt source is determined by reading the flag register INTFLG. The flag is cleared when read. Whether this releasing interrupt source causes the counter to count up or down depends on whether the state of the releasing input satisfies the condition for counting up or down.

Figure	3.10.43	INTFLG	Register
riguio	0.10.40		register

• In STOP mode

The 2-phase pulse input counter stops. Enable the INTBCDE release input in the clock generator (CG). An up or down counter input generates an INTB or INTC interrupt, causing the counter to exit from STOP mode. Whether this releasing input causes the counter to count up or down depends on the relationship between the input state prior to entering STOP mode and the state of the releasing input.

After the releasing input is asserted, the device warms up for the specified period before entering NORMAL or SLOW mode to restart counting.

## d. Up/down-counter

When 2-phase input counter mode is selected (TB2RUN<TB2UDCE> = 1), the up-counter is initialized to 0x7FFF and operates as an up/down-counter. If the counter overflows, it is initialized to 0x0000 and continues counting. If the counter underflows, it is initialized to 0xFFFF and continues counting. Therefore, you can determine the state of the counter by reading the counter value and the status flag TB2ST after an interrupt occurs.

Sampling clock			
Count up input			
Up/down-counter value	0x3FFF	0x4000	0x4001
Up/down interrupt	ĺ		1

Note 1: Ensure that the count up (down) input is High before and after it is input.

Note 2: The counter value must be read during exception handling for INTTB2. If the counter value is read during exception handling for INTB or INTC used to terminate SLEEP or STOP mode, the counter value varies depending on whether the condition is satisfied or not and the difference in time between SLEEP/STOP mode being terminated and counting being restarted.

# 3.11 Serial Channels (SIO)

The TMP1942 contains five serial input/output channels: SIO0, SIO1, SIO3, SIO4 and SIO5. Each channel can be operated in (asynchronous) UART mode or (synchronous) I/O interface mode, as shown below.

- I/O interface mode Mode 0: Transmit and receive I/O data using the sync signal (SCLK) for extended I/O operation.
- Asynchronous (UART) mode Mode 1: Transmit and receive 7-bit data.
   Mode 2: Transmit and receive 8-bit data. Mode 3: Transmit and receive 9-bit data.

In modes 1 and 2 a parity bit can be added. Mode 3 supports a wake-up function which is used by the master controller in a multi-controller system to initiate communication with a slave controller via a serial link. Figure 3.11.2 shows a block diagram for SIO0.

Each channel consists of a prescaler, a serial clock generator, a receive buffer and its accompanying control circuit, and a transmit buffer and its accompanying control circuit. All channels operate independently of each other. Because all channels operate in the same way, this section consists only of an explanation for SIO0.

• Mode 0 (I/O interface mode): LSB first

• Mode 0 (I/O interface mode): MSB first

• Mode 1 (7-bit UART mode)

Without parity 
$$tart bit 0 1 2 3 4 5 6$$
 stop  
With parity  $tart bit 0 1 2 3 4 5 6$  parity stop

Mode 2 (8-bit UART mode)

Without parity 
$$tart bit 0 1 2 3 4 5 6 7 stop$$
  
With parity  $tart bit 0 1 2 3 4 5 6 7 stop$ 

Mode 3 (9-bit UART mode)

Figure 3.11.2 SIO0 Block Diagram

# 3.11.2 Functional description of each circuit (for channel 0 as an example)

(1) Prescaler

The TMP1942 has a 6-bit prescaler to supply an operating clock to SIO0. The prescaler's input clock  $\phi$ T0 has a frequency of fperiph, fperiph/2 or fperiph/4 as selected by SYSCR0 <PRCK1:PRCK0> in the CG block.

fperiph is either the clock fgear as selected by SYSCR1<FPSEL> in the CG block or the clock fc before division by the clock gear.

The prescaler operates only when the baud rate generator has been specified as the serial transfer clock. Table 3.11.1 shows the resolutions of the prescaler output clocks.

		-				@ = 32 MHz		
Peripheral	Clock Gear	Selected	Prescaler Output Clock Resolution					
Clock Selection <fpsel></fpsel>	Value <gear1:0></gear1:0>	Prescaler Clock <prck1:0></prck1:0>	φTΟ	φ <b>T</b> 2	φΤ8	φ <b>T</b> 32		
		00 (fperiph/4)	fc/2 <sup>2</sup> (0.125 μs)	fc/2 <sup>4</sup> (0.5 μs)	fc/2 <sup>6</sup> (2.0 μs)	fc/2 <sup>8</sup> (8.0 μs)

Table 3.11.1 Baud Rate Generator Input Clock Resolutions

Note 1: The prescaler's output clock φTn must be selected such that the relationship φTn < fsys/2 is satisfied (i.e., φTn must be slower than fsys/2).

Note 2: Do not change the clock gear value while the timer is running

Note 3: The -- character means "Don't use"

One of prescaler output clocks -  $\phi$ T0,  $\phi$ T2,  $\phi$ T8 or  $\phi$ T32 - is used for the serial interface baud rate generator.

## (2) Baud rate

The baud rate generator is used to generate the transmit/receive clock which determines the rate at which data is transferred via serial channels.

The clock source fed to the baud rate generator is the clock  $\phi$ T0,  $\phi$ T2,  $\phi$ T8 or  $\phi$ T32 as output by the 6-bit prescaler. This input clock is selected by setting the bits BR0CR<BR0CK1:BR0CK0> in the baud rate generator control register.

The baud rate generator contains a divider which can divide the input clock frequency by 1,  $n + \frac{m}{16}$  (n = 2-15, m = 0-15) or 16. The input clock frequency is divided according to the values set in BR0CR<BR0ADDE,BR0S3:BR0S0> and BR0ADD<BR0K3:BR0K0> to specify the rate of transfer.

- For UART mode
- 1) When BR0CR<BR0ADDE> = 0

The value set in BR0ADD<BR0K3:BR0K0> is ignored and the input clock is divided by the value N set in BR0CR<BR0S3:BR0S0> (N = 1, 2, 3... 16).

2) When BR0CR<BR0ADDE> = 1

The input clock is divided by N+(16-K)/16, where the value of N is specified by BR0CR  $\langle BR0S3:BR0S0 \rangle$  (N = 2, 3... 15) and the value of K is specified by BR0ADD $\langle BR0K3:0 \rangle$  (K = 1, 2, 3... 15).

```
Note: When N = 1 or 16, division by N+(16-K)/16 is disabled. In that case, always set BR0CR<BR0ADDE> to 0.
```

## • For I/O interface mode

Division by N+(16-K)/16 cannot be used in I/O interface mode. In this mode always set BR0CR<BR0ADDE> to 0 so that the input clock will be divided by N.

The baud rate is calculated as follows:

• In UART mode

Baud rate =  $\frac{\text{Baud rate generator input clock}}{\text{Baud rate generator divisor}} \div 16$ 

The maximum baud rate which can be generated by the baud rate generator is 500 kbps and is generated when  $\phi T0 = 8$  MHz.

In addition to an output from the baud rate generator, fsys/2 can also be used as a serial clock. If fsys/2 is used as a serial clock, the maximum baud rate is 1 Mbps, which is generated when fsys = 32 MHz.

In I/O interface mode

Baud rate =  $\frac{\text{Baud rate generator input clock}}{\text{Baud rate generator divisor}} \div 2$ 

• When dividing the input clock by an integer (N)

If  $\phi$ T2 is chosen as the input clock to the baud rate generator with the divisor N (BR0CR<BR0S3:BR0S0>) set to 10 and BR0CR<BR0ADDE> set to 0 after fc = 24.576 MHz has been specified as fperiph and  $\phi$ T0 has been set to fperiph/4, then the baud rate in UART mode is calculated as follows:

\* Clock conditions  $\begin{cases} \text{System clock} & : \text{High-speed (fc)} \\ \text{High-speed clock gear} & : \times 1 \text{ (fc)} \\ \text{Prescaler clock} & : \text{fperiph/4 (fperiph = fsys)} \end{cases}$ Baud rate =  $\frac{\text{fc}/16}{10} \div 16$ 

 $= 24.576 \times 10^6 \div 16 \div 10 \div 16 = 9600$  (bps)

Note: Since division by N+(16-K)/16 is disabled, the value set in BR0ADD<BR0K3:BR0K0> is ignored.

• When dividing the input clock by N+(16-K)/16 (UART mode only)

If  $\phi$ T2 is chosen as the input clock to the baud rate generator with the divisor N (BR0CR<BR0S3:BR0S0>) set to 7, K (BR0ADD<BR0K3:BR0K0>) set to 3 and BR0CR<BR0ADDE> set to 1 after fc = 19.2 MHz has been specified as fperiph and  $\phi$ T0 has been set to fperiph/4, the baud rate is calculated as follows:

```
* Clock conditions 

System clock : High-speed (fc)

High-speed clock gear : × 1 (fc)

Prescaler clock : fperiph/4 (fperiph = fsys)

Baud rate = \frac{fc/16}{7 + \frac{16-3}{16}} \div 16

= 19.2 × 10<sup>6</sup> ÷ 16 ÷ (7 + \frac{13}{16}) ÷ 16 = 9600 (bps)
```

Tables 3.11.2 and 3.11.3 show example baud rates in UART mode.

Instead of a prescaler output, a clock input from an external source can also be used as the serial clock. In this case the baud rate is calculated as follows:

• UART mode

Baud rate = external clock input/16

However, the period of the external clock must be greater than or equal to 4/fsys.

• I/O interface mode

Baud Rate = external clock input However, the period of the external clock must be greater than or equal to 16/fsys.

# Table 3.11.2 UART Baud Rate Selection (When the baud rate generator is used and BR0CR<BR0ADDE> = 0)

					Units: kbps			
	Divisor N	Input Clock

19.6608	1	307.200	76.800	19.200	4.800			
$\uparrow$	2	153.600	38.400	9.600	2.400			
$\uparrow$	4	76.800	19.200	4.800	1.200			
$\uparrow$	8	38.400	9.600	2.400	0.600			
$\uparrow$	0	19.200	4.800	1.200	0.300			
24.576	5	76.800	19.200	4.800	1.200			
$\uparrow$	А	38.400	9.600	2.400	0.600			
29.4912	1	460.800	115.200	28.800	7.200			
$\uparrow$	2	230.400	57.600	14.400	3.600			
$\uparrow$	3	153.600	38.400	9.600	2.400			
$\uparrow$	4	115.200	28.800	7.200	1.800			
$\uparrow$	6	76.800	19.200	4.800	1.200			
$\uparrow$	С	38.400	9.600	2.400	0.600			

Note: The values shown in the table above are applied when the system clock frequency = fc, the clock gear = fc/1 and the prescaler clock frequency = fperiph/4.

# Table 3.11.3 UART Baud Rate Selection

(When TMRA6 timer trigger output is used and TMRA6 input clock =  $\phi$ T1)

						Units: kbps					
<b>TA0REG</b>	fc										
TAUREG	29.4912 MHz	24.576 MHz	24 MHz	19.6608 MHz	16 MHz	12.288 MHz					
1H	230.4	192	187.5	153.6	125	96					
2H	115.2	96	93.75	76.8	62.5	48					
ЗH	76.8	64	62.5	51.2	41.67	32					
4H	57.6	48	46.88	38.4	31.25	24					
5H	46.08	38.4	37.5	30.72	25	19.2					
6H	38.4	32	31.25	25.6	20.83	16					
8H	28.8	24	23.44	19.2	15.63	12					
AH	23.04	19.2	18.75	15.36	12.5	9.6					
10H	14.4	12	11.72	9.6	7.81	6					
14H	11.52	9.6	9.38	7.68	6.25	4.8					

Calculate the baud rate as follows (when timer TMRA6 is used):

Transfer rate = 
$$\frac{\text{Clock frequency specified with SYSCR0 < PRCK1: PRCK0 >}}{\text{TA0REG} \times 2 \times 16}$$

(when TMRA6 input clock =  $\phi$ T1)

Note 1: The trigger signal from timer TMRA6 cannot be used as the transfer clock in I/O interface mode.
Note 2: The values shown in the table above are applied when the system clock frequency = fc, the clock gear = fc/1, and the prescaler clock frequency = fperiph/4.

(3) Serial clock generator

This circuit generates a basic clock used to transmit and receive data.

• For I/O interface mode

In SCLK output mode (when SCOCR<IOC> = 0), the basic clock is generated by dividing the baud rate generator output, described above, by 2.

In SCLK input mode (when SCOCR < IOC > = 1), the basic clock is generated by detecting either the rising or falling edges of the SCLK input, as specified by the SCOCR < SCLKS > setting.

• For asynchronous (UART) mode

One of the following four sources is selected to generate the basic clock SIOCLK: the clock output by the baud rate generator as described above, the system clock (fsys/2), the trigger output signal from timer TMRA6, or the external clock (on the SCLK0 pin). The setting of SC0MOD0<SC1:SC0> specifies which source is selected.

(4) Receive counter

The receive counter is a 4-bit binary counter which is used in asynchronous (UART) mode. This counter is incremented every time a SIOCLK pulse is detected. Receiving one bit of data requires 16 SIOCLK pulses and data is sampled three times: at the seventh, eighth and ninth pulses. The received data is determined from the three samples by majority rule.

- (5) Receive controller
  - For I/O interface mode

In SCLK output mode (when SCOCR < IOC > = 0), the RXD0 pin is sampled at the rising edge of the shift clock which is output to the SCLK0 pin.

In SCLK input mode (when SCOCR < IOC > = 1), the RXD0 pin is sampled at either the rising or falling edge of the SCLK input, as specified by the setting of SCOCR < SCLKS >.

• For asynchronous (UART) mode

The receive controller incorporates a start bit detection circuit so that it can start receive operation upon the detection of a valid start bit.

## (6) Receive buffer

The receive buffer has double-buffer structure to prevent overrun errors. Received data is stored one bit at a time in receive buffer 1 (a shift register). When all bits of data have been received, the data is transferred to another receive buffer, receive buffer 2 (SC0BUF), at which point an INTRX0 interrupt is generated. Also, the receive buffer full flag (SC0MOD2<RBFLL>) is set to 1 simultaneously, indicating that receive buffer 2 contains valid data.

The CPU reads data from receive buffer 2 (SC0BUF). This read causes the RBFLL flag to be cleared to 0. Next received data can be stored in receive buffer 1 even before the CPU reads the data out from receive buffer 2 (SC0BUF).

When SCLK output is selected in I/O interface mode, receive buffer 2 (SCOBUF) can be enabled or disabled by setting SCOMOD2<WBUF> accordingly. Disabling receive buffer 2 allows the device to handshake with the remote device it is communicating with, so that it stops CLK output every time it has sent a single frame. In that case, the CPU reads data from receive buffer 1. This read causes CLK output to restart. When receive buffer 2 is enabled in I/O interface mode, operation is as follows: The first received data is transferred from receive buffer 1 to receive buffer 2. CLK output stops when the next data has been received and both receive buffers 1 and 2 contain valid data. Once the CPU has read data from receive buffer 2, the data in receive buffer 1 is transferred to receive buffer 2, at which point an INTRX0 interrupt is generated and CLK output is restarted. Therefore, no overrun error occurs in SCLK output I/O interface mode, regardless of the WBUG setting.

Note: In this mode the SC0CR OEER flag has no meaning, resulting in undefined operation. Be sure to read SC0CR to initialize this flag before changing the mode from SCLK output mode.

In other operating modes, receive buffer 2 is always enabled to improve performance for continuous transfer. However, if the CPU has not read the data out from receive buffer 2 (SC0BUF) by the time all the bits of the next data item have been received into receive buffer 1, an overrun error will occur. If an overrun error occurs, the contents of receive buffer 1 will be lost; the contents of receive buffer 2 and SC0CR<RB8> will be retained.

SC0CR<RB8> stores either the parity bit which is added to 8-bit UART data or the most significant bit of 9-bit UART data.

In 9-bit UART mode, slave controller wake-up operation can be enabled by setting SC0MOD0<WU> to 1. In this case, an INTRX0 interrupt is only generated if SC0CR<RB8> = 1.

## (7) Transmit counter

The transmit counter is a 4-bit binary counter used in asynchronous (UART) mode. Like the receive counter, this counter is incremented every time a SIOCLK pulse is detected and generates a transmit clock (TXDCLK) pulse every 16 SIOCLK pulses.

- (8) Transmit controller
  - In I/O interface mode

In SCLK output mode (when SC0CR<IOC> = 0), data is output from the transmit buffer to the TXD0 pin one bit at a time at each rising edge of the shift clock output on the SCLK0 pin.

In SCLK input mode (when SC0CR<IOC> = 1), data is output from the transmit buffer to the TXD0 pin one bit at a time, either at each rising edge or each falling edge of the SCLK input as specified by the setting of SC0CR<SCLKS>.

• In asynchronous (UART) mode

After transmit data has been written to the transmit buffer by the CPU, the transmit controller will start transmitting the data at the next rising edge of TXDCLK, thus generating a transmit shift clock (TXDSFT).

## Handshaking function

The device has a  $\overline{\text{CTS}}$  pin, which makes it possible to transmit data in frame units, preventing overrun errors from occurring. This function can be enabled or disabled using SC0MOD<CTSE>.

When the  $\overline{\text{CTS0}}$  pin goes High, the transmitter stops transmission after it has finished sending the current data and remains idle until the  $\overline{\text{CTS0}}$  pin goes back to Low. The transmit controller generates an INTTX0 interrupt to request the next transmission of data from the CPU and, after writing the data to the transmit buffer, will wait for the new data to be sent.

Although the device does not have an  $\overline{\text{RTS}}$  pin, the handshaking function can be implemented in the following way: One of the receiver's ports can be assigned to the function and when the receiver has finished receiving data, it drives that port High (using the receive interrupt routine), thereby requesting the transmitter to temporarily suspend transmission.

TMP1942CY/CZ-245

# (9) Transmit buffer

The transmit buffer (SC0BUF) has double-buffer structure. The double-buffer can be enabled or disabled by setting SC0MOD1<WBUF> accordingly. When the double-buffer is enabled, data written to transmit buffer 2 (SC0BUF) is transferred to transmit buffer 1 (a shift register), at which point an INTTX interrupt is generated. Also, the SCnMOD2 TBEMP flag is set to 1 simultaneously, indicating that transmit buffer 2 is empty so that next transmit data can be written. The TBEMP flag is cleared to 0 when next transmit data is written to transmit buffer 2. When the double-buffer is disabled, the CPU writes transmit data to transmit buffer 1 and an INTTX interrupt occurs upon the completion of transmission.

Note: In this mode the SC0CR UEER flag has no meaning, resulting in undefined operation. Be sure to read SC0CR to initialize this flag before changing the mode from SCLK output mode.

If it is necessary to handshake with the remote device, set WBUF to 0 to disable transmit buffer 2. To perform continuous transmission without handshaking, you can improve performance by setting WBUF to 1 to enable transmit buffer 2.

#### (10) Parity controller

Data transmission with parity is enabled by setting the PE bit of the serial channel control register SC0CR to 1. Note, however, that parity can only be used in 7-bit UART mode or 8-bit UART mode. The SC0CR<EVEN> bit can be used to select even or odd parity.

During transmission the parity controller automatically generates parity bits from the data written to the transmit buffer (SC0BUF). Upon the completion of transmitting the data, it stores the parity in SC0BUF<TB7> in 7-bit UART mode or SC0MOD0<TB8> in 8-bit UART mode. The PE and EVEN bits in the SC0CR register must be set before the transmit data is written to the transmit buffer.

During reception the parity controller automatically generates parity bits from the data which has been shifted in and transferred from receive buffer 1 to receive buffer 2 (SC0BUF), and compares it with the parity stored in SC0BUF<RB7> in 7-bit UART mode or SC0CR<RB8> in 8-bit UART mode. If the parities do not match, a parity error is generated, setting the SC0CR<PERR> flag.

In I/O interface mode, SCOCR<PERR> is not a parity flag but functions as an underrun error flag.

## (11) Error flags

Three error flags are available for the purpose of increasing the reliability of the received data.

1. Overrun error <OERR>

In both UART and I/O interface modes, an overrun error occurs when all bits of the next frame have been received before data stored in the receive buffer is read out completely. An overrun error causes the OERR flag to be set. Reading the flag clears it to 0. If SCLK output is selected in I/O interface mode, however, this flag is undefined because no overrun error will occur.

2. Parity error/underrun error <PERR>

In UART mode, the PERR flag is set to 1 when a parity error occurs. A parity error occurs if the parity calculated from the received data differs from the received parity bit. Reading the PERR flag clears it to 0.

In I/O interface mode, the PERR bit indicates an underrun error. When SC0MOD2<WBUF> is set to 1, an underrun error occurs in the following case: In SCLK input mode, it occurs if data stored in the transmit shift register has been transmitted but no data is set in the transmit double-buffer before the next transfer clock is input. In SCLK output mode, this flag is undefined because no underrun error will occur. The PERR flag is not set when transmit buffer 2 is disabled. Reading the flag clears it to 0.

3. Framing error <FERR>

In UART mode, the FERR flag is set to 1 when a framing error occurs. Reading the flag clears it to 0. A framing error occurs if the stop bit in the received data is detected as being 0 when sampled around the center.

Operating Mode	Error Flag	Description		
UART	OERR	Overrun error flag		
	PERR	Parity error flag		
	FERR	Framing error flag		
I/O interface	OERR	Overrun error flag		
(SCLK input)	PERR	Underrun error flag (WBUF = 1)		
		Fixed to 0 (WBUF = 0)		
	FERR	Fixed to 0		
I/O interface	OERR	Undefined		
(SCLK output)	PERR	Undefined		
	FERR	Fixed to 0		

Note:FERR reading occurs during the interruption handling must be executed before a receive buffer reading. Polling for reading FERR is prohibited. See the example in 3.11.4 (3) Mode 2 (8-bit UART Mode) for the details.

(12) Direction of data transfer

In I/O interface mode, the direction of transfer can be toggled between MSB first and LSB first by setting SCnMOD2<DRCHG>. Do not change the direction of transfer while data is being transferred.

## (13) STOP bit length

In UART mode, the STOP bit length in transmit data can be toggled between one bit and two bits by setting SCnMOD2<SBLEN>.

#### (14) Status flag

The SCnMOD2<RBFLL> bit is a flag which indicates that the receive buffer is full when the double-buffer is enabled (WBUF = 1). Once a single frame of data has been received and the data has been transferred from receive buffer 1 to receive buffer 2, this flag is set to 1, indicating that buffer 2 is full (contains data). When the CPU/DMAC reads the receive buffer, the flag is cleared to 0. When WBUF = 0, the RBFLL bit has no meaning and cannot be used as a status flag. TBEMP is a flag which indicates that transmit buffer 2 is empty when the double-buffer is enabled (WBUF = 1). Once data has been transferred from transmit buffer 2 to transmit buffer 1 (a shift register), this flag is set to 1, indicating that transmit buffer 2 is empty. When the CPU/DMAC writes data to the transmit buffer, the flag is cleared to 0. When WBUF = 0, the TBEMP bit has no meaning and cannot be used as a status flag.

#### (15) Transmit/receiver buffer configuration

		WBUF = 0	WBUF = 1
UART	Transmit	SINGLE	DOUBLE
UNIT	Receive	DOUBLE	DOUBLE
I/O interface	Transmit	SINGLE	DOUBLE
(SCLK input)	Receive	DOUBLE	DOUBLE
I/O interface	Transmit	SINGLE	DOUBLE
(SCLK output)	Receive	SINGLE	DOUBLE

#### (16) Signal generation timing

#### 1) UART mode

Reception

		Mode						
	9 bits	8 bits + parity	8 bits, 7 bits + parity, or 7 bits					
Interrupt generation timing	Center of first stop bit	Center of first stop bit	Center of first stop bit					
Framing error generation timing	Center of stop bit	Center of stop bit	Center of stop bit					
Parity error generation timing	_	Center of last bit (parity bit)	Center of last bit (parity bit)					
Overrun error generation timing	Center of stop bit	Center of stop bit	Center of stop bit					

#### Transmission

	Mode						
	9 bits	8 bits + parity	8 bits, 7 bits + parity, or 7 bits				
Interrupt generation timing (WBUF = 0)	Immediately before stop bit is sent	Immediately before stop bit is sent	Immediately before stop bit is sent				
Interrupt generation timing (WBUF = 1)	Immediately after data is transferred to transmit buffer 1 (immediately before start bit is sent)	Immediately after data is transferred to transmit buffer 1 (immediately before start bit is sent)	Immediately after data is transferred to transmit buffer 1 (immediately before start bit is sent)				

2) I/O interface mode

# Reception

Interrupt generation timing (WBUF = 0)	SCLK output mode	Immediately after rise of last SCLK pulse
	SCLK input mode	Immediately after rise of last SCLK pulse (rise mode); in fall mode, immediately after fall of last SCLK pulse
Interrupt generation timing (WBUF = 1)	SCLK output mode	Immediately after rise of last SCLK pulse (immediately after data is transferred to receive buffer 2) or immediately after data is read from receive buffer 2
	SCLK input mode	Immediately after rise of last SCLK pulse (rise mode); in fall mode, immediately after fall of last SCLK pulse (immediately after data is transferred to receive buffer 2)
Overrun error	SCLK output mode	Immediately after rise of last SCLK pulse
generation timing	SCLK input mode	Immediately after rise of last SCLK pulse (rise mode); in fall mode, immediately after fall of last SCLK pulse

# Transmission

Interrupt	SCLK output mode	Immediately after rise of last SCLK pulse
generation timing (WBUF = 0)	SCLK input mode	Immediately after rise of last SCLK pulse (rise mode); in fall mode, immediately after fall of last SCLK pulse
Interrupt generation timing	SCLK output mode	Immediately after rise of last SCLK pulse or immediately after data is transferred to transmit buffer 1
(WBUF = 1)	SCLK input mode	Immediately after rise of last SCLK pulse (rise mode); in fall mode, immediately after fall of last SCLK pulse; or immediately after data is transferred to transmit buffer 1
Underrun error	SCLK output mode	Immediately after rise of last SCLK pulse
generation timing	SCLK input mode	Immediately after rise of next SCLK pulse (rise mode); in fall mode, immediately after fall of next SCLK pulse

Note 1:	Do not modify any control register during transmission or reception
	(while reception is enabled).
Note 2:	Do not disable reception (by setting SC0MOD0 <rxe> to 0) while data is being</rxe>

received.

- <SWRST1:0>: Writing 10 and 01 in this order triggers a software reset. This initializes the mode register bits SC0MOD0<RXE>, SC0MOD2<TBEMP>, <RBFIL> and <TXRUN>, control register bits SC0CR<OERR>, <PERR> and <FERR>, and the internal logic.
- <WBUF>: Enables or disables the double-buffer for transmission (SCLK output/input) and reception (SCLK output) in I/O interface mode and transmission in UART mode. In other modes, the double-buffer is always enabled regardless of the setting.
- <DRCHG>: Specifies the direction of transfer in I/O interface mode. In UART mode, this bit is fixed to 0 (LSB first).
- <TXRUN>: This bit is a status flag which indicates whether transmission shift operation is in progress. When this bit is set to 1, it indicates that data is being transmitted. When this bit is set to 0, it indicates that transmission is completely finished (if TBEMP = 1) or that the device is waiting with next transmit data stored in the transmit buffer (if TBEMP = 0).
- <RBFLL>: This bit is a flag which indicates whether the receive double-buffer is full. RBFIL is set to 1 when data has been transferred from the receive shift register to the receive double-buffer. It is cleared to 0 when the data has been read. This flag has no meaning if the double-buffer is disabled.
- <TBEMP>: This bit is a flag which indicates whether the transmit double-buffer is empty. TBEMP is set to 1 when data has been transferred from the transmit double-buffer to the transmit shift register, resulting in the transmit double-buffer being empty. It is cleared to 0 when transmit data has been written to the double-buffer. This flag has no meaning if the double-buffer is disabled.
- <SBLEN>: Specifies the transmit STOP bit length in UART mode. During reception, the device always recognizes a single STOP bit regardless of the setting of this bit.

Note: If it is necessary to perform a soft reset during transmission, perform it twice consecutively.

- <SWRST1:0>: Writing 10 and 01 in this order triggers a software reset. This initializes the mode register bits SC5MOD0<RXE>, SC5MOD2<TBEMP>, <RBFIL> and <TXRUN>, control register bits SC5CR<OERR>, <PERR> and <FERR>, and the internal logic.
- <WBUF>: Enables or disables the double-buffer for transmission (SCLK output/input) and reception (SCLK output) in I/O interface mode and transmission in UART mode. In other modes, the double-buffer is always enabled regardless of the setting.
- <DRCHG>: Specifies the direction of transfer in I/O interface mode. In UART mode, this bit is fixed to 0 (LSB first).
- <TXRUN>: This bit is a status flag which indicates whether transmission shift operation is in progress. When this bit is set to 1, it indicates that data is being transmitted. When this bit is set to 0, it indicates that transmission is completely finished (if TBEMP = 1) or that the device is waiting with next transmit data stored in the transmit buffer (if TBEMP = 0).
- <RBFLL>: This bit is a flag which indicates whether the receive double-buffer is full. RBFIL is set to 1 when data has been transferred from the receive shift register to the receive double-buffer. It is cleared to 0 when the data has been read. This flag has no meaning if the double-buffer is disabled.
- <TBEMP>: This bit is a flag which indicates whether the transmit double-buffer is empty. TBEMP is set to 1 when data has been transferred from the transmit double-buffer to the transmit shift register, resulting in the transmit double-buffer being empty. It is cleared to 0 when transmit data has been written to the double-buffer. This flag has no meaning if the double-buffer is disabled.
- <SBLEN>: Specifies the transmit STOP bit length in UART mode. During reception, the device always recognizes a single STOP bit regardless of the setting of this bit.

Note: If it is necessary to perform a soft reset during transmission, perform it twice consecutively.

Figure 3.11.20 Serial Mode Control Register 2 (SC5MOD2, for SIO5)

Note 2: For SCLK output operation, set SCLKS to 0 (rising edge).

Figure 3.11.21 Serial Control Register (SC0CR, for SIO0)

Note 2: For SCLK output operation, set SCLKS to 0 (rising edge).

Figure 3.11.22 Serial Control Register (SC1CR, for SIO1)

- <OERR>: In both UART and I/O interface modes, an overrun error occurs when all bits of the next frame have been received before data stored in the receive buffer is read out completely. An overrun error causes the OERR flag to be set.
- <PERR>: In UART mode, the PERR flag is set to 1 when a parity error occurs. Reading the PERR flag clears it to 0. In I/O interface mode, the PERR bit indicates an underrun error. When SC0MOD2<WBUF> is set to 1, an underrun error occurs in the following case: In SCLK input mode, it occurs if data stored in the transmit shift register has been transmitted but no data is set in the transmit double-buffer. In other modes, this flag is not set. Reading the flag clears it to 0.
- <FERR>: In UART mode, the FERR flag is set to 1 when a framing error occurs. Reading the flag clears it to 0.

Note 2: For SCLK output operation, set SCLKS to 0 (rising edge).

Figure 3.11.23 Serial Control Register (SC3CR, for SIO3)

1		+ (16-K)/16	
1111 (K = 15)			

- Note 1: The baud rate generator divisor cannot be set to 1 in UART mode if division by N+(16-K)/16 is being used. It cannot be set to 1 at all in I/O interface mode.
- Note 2: When using division by N+(16-K)/16, be sure to set K (1 to 15) in BR5ADD <BR5K3:BR5K0> before setting BR5CR<BR5ADDE> to 1. However, if BR5CR <BR5S3:BR5S0> = 0000 or 0001 (i.e. if N = 16 or 1), do not use division by N+(16-K)/16.
- Note 3: Division by N+(16-K)/16 can only be used in UART mode. In I/O interface mode, set BR5CR<BR5ADDE> to 0 to disable division by N+(16-K)/16.

Figure 3.11.35 Serial Transmit/Receive Buffer Register (SC5BUF, for SIO5)

### 3.11.4 Functional description for each mode

(1) Mode 0 (I/O interface mode)

This mode comprises two submodes: SCLK output mode, in which the synchronizing clock SCLK is generated internally by the device, and SCLK input mode, in which the synchronizing clock SCLK is input from an external source.

1) Transmission

If WBUF = 0, that is, the transmit double-buffer is disabled in SCLK output mode, 8 bits of data and the synchronizing clock signal are output on the TXD0 and SCLK0 pins, respectively, each time the CPU writes data to the transmit buffer. When all the data bits have been output, an INTTX0 interrupt is generated.

If WBUF = 1, that is, the transmit double-buffer is enabled, data is transferred from transmit buffer 2 to transmit buffer 1 when the CPU writes data to transmit buffer 2 while transmission is stopped or when data has been transmitted from transmit buffer 1 (shift register). Simultaneously, SC0MOD2<TBEMP> is set to 1 and an INTTX0 interrupt occurs. If transmit buffer 2 does not contain data to be transferred to transmit buffer 1, SCLK0 output is stopped without generating an INTTX0 interrupt.

Figure 3.11.36 Transmit Operation in I/O Interface Mode (SCLK0 Output Mode)

If WBUF = 0, that is, the transmit double-buffer is disabled in SCLK input mode, 8 bits of data are output on the TXD0 pin when the SCLK0 input becomes active with data present in the transmit buffer. When all the data bits have been output, an INTTX0 interrupt is generated. Writing the next transmit data must be completed before point A in the shown below.

If WBUF = 1, that is, the transmit double-buffer is enabled, data is transferred from transmit buffer 2 to transmit buffer 1 when the CPU writes data to the transmit buffer before the SCLK0 input becomes active or when data has been transmitted from transmit buffer 1 (shift register). Simultaneously, SC0MOD2<TBEMP> is set to 1 and an INTTX0 interrupt occurs. If the SCLK0 input becomes active when transmit buffer 2 does not contain data, the internal bit counter starts counting but an underrun error flag is set, causing 8 bits of dummy data (FFh) to be transmitted.

#### 2) Reception

If WBUF = 0, that is, the receive double-buffer is disabled in SCLK output mode, the synchronizing clock is output on the SCLK0 pin and the next data item is shifted into receive buffer 1 each time the received data is read by the CPU. When 8 bits of data have been received, an INTRX0 interrupt is generated.

SCLK output is initiated by setting SC0MOD0<RXE> to 1. If WBUF = 1, that is, the receive double-buffer is enabled, the received frame is transferred to transmit buffer 2 and then the next frame is received into receive buffer 1. When data has been transferred from receive buffer 1 to receive buffer 2, SCnMOD2<RBFLL> is set to 1 and an INTRX0 interrupt occurs.

If the CPU/DMAC does not read data from receive buffer 2 before the next eight bits of data have been received, an overrun error occurs, setting SCnCR<OERR>. In that case, SCLK0 output is stopped without generating an INTRX0 interrupt. After an overrun error occurs, reading data from receive buffer 2 causes the data in receive buffer 1 to be transferred to receive buffer 2, generating an INTRX0 interrupt to restart reception.

Figure 3.11.38 Receive Operation in I/O Interface Mode (SCLK0 Output Mode)

In SCLK input mode, the receive double-buffer is always enabled. The received frame is transferred to receive buffer 2, so that receive buffer 1 can receive the next frame immediately.

Each time received data has been transferred to receive buffer 2, an INTRX0 interrupt occurs.

Note: Before receive operation can be performed in either SCLK input mode or SCLK output mode, reception must be enabled by setting SC0MOD<RXE> to 1.

3) Transmission/reception (full-duplex)

Setting SC0MOD1<FDPX0> to 1 enables full-duplex communication.

If WBUF = 0, that is, both the transmit and receive double-buffers are disabled in SCLK output mode, writing data to the transmit buffer initiates SCLK output and shifts the received 8-bit data into receive buffer 1, generating a receive interrupt (INTRX0). Simultaneously, the 8-bit data written to the transmit buffer is output on the TXD0 pin. When all bits of data have been transmitted, a transmit interrupt (INTTX0) is generated, causing SCLK output to stop. When the CPU subsequently reads the receive buffer and writes data to the transmit buffer, next transmission/reception starts. Transmission/reception is restarted when the CPU has performed both the read and write, regardless of their sequence.

If WBUF = 1, that is, both the transmit and receive double-buffers are enabled, writing data to the transmit buffer initiates SCLK output and shifts the received 8-bit data into receive buffer 1, which is then transferred to receive buffer 2, generating a receive interrupt (INTRX0). Simultaneously, the 8-bit data written to the transmit buffer is output on the TXD0 pin. When all bits of data have been transmitted, a transmit interrupt (INTTX0) is generated and the next data is transferred from transmit buffer 2 to transmit buffer 1. If transmit buffer 2 does not contain data to be transferred (TBEMP = 1) or receive buffer 2 contains data (RBFLL = 1), SCLK output is stopped. When the CPU subsequently reads the receive buffer and writes data to the transmit buffer, SCLK output is restarted and next transmission/reception starts.

Figure 3.11.40 Transmit/Receive Operation in I/O Interface Mode (SCLK0 Output Mode)

If WBUF = 0, that is, the transmit double-buffer is disabled in SCLK input mode (the receive double-buffer is always enabled in SCLK input mode), 8-bit data is output on the TXD0 pin and 8-bit data is shifted into the receive buffer simultaneously when the SCLK input becomes active with data present in the transmit buffer. When all bits of data have been transmitted, a transmit interrupt (INTTX0) is generated. When all bits of data have been received and then transferred from receive buffer 1 to receive buffer 2, a receive interrupt (INTRX0) is generated. Next transmit data must be written to the transmit buffer before the SCLK pulse for the next frame is input, that is, before point A in the figure below. Because the receive double-buffer is enabled, the received data must be read before the receiption of the next frame is completed.

If WBUF = 1, that is, both the transmit and receive double-buffers are enabled, the data in transmit buffer 2 is transferred to transmit buffer 1, generating a transmit interrupt (INTTX0), when all bits of data in transmit buffer 1 have been transmitted. When the received 8-bit data has been shifted into receive buffer 1, the data is transferred to receive buffer 2, generating a receive interrupt (INTRX0). Then, the SCLK input pulse for the next frame initiates the transmission of the data transferred from transmit buffer 2 to transmit buffer 1 and the reception of data into receive buffer 1. If the data in receive buffer 2 is not read before the last bit of the frame is received, an overrun error occurs. If transmit data is not written to transmit buffer 2 before the SCLK pulse for the next frame is input, an underrun error occurs.

When WBUF = 1 (if error occurs)

(2) Mode 1 (7-bit UART mode)

Setting the SM1 and SM0 bits of the serial channel mode register SC0MOD to 01 places the device into 7-bit UART mode.

In this mode, a parity bit can be used. Parity can be enabled or disabled using the PE bit of the serial channel control register SCOCR. When PE = 1 (parity enabled), even or odd parity can be selected using SCOCR<EVEN>. The STOP bit length can also be specified using SCnMOD2<SBLEN>.

	start bit 0 1	2 $3$ $4$ $5$ rection of transfer (transfer rate =	6 veven stop = 2400 bps at fc = 24.576 MHz)
2	Clock conditions	System clock: High-speed clock gear: Prescaler clock:	High-speed (fc) × 1 (fc) f <sub>periph/4</sub> (f <sub>periph</sub> = f <sub>sys</sub> )
	76543210	)	
PDCR	$\leftarrow 2$	Set PD0 to TXD0 pin.	
PDFC	$\leftarrow$		
SCOMOD	$\leftarrow \texttt{X} \texttt{0} - \texttt{X} \texttt{0} \texttt{1} \texttt{0} \texttt{2}$	Select 7-bit UART mo	ode.
SCOCR	$\leftarrow$ X 1 1 X X X 0 (	Select even parity.	
BROCR	$\leftarrow 0 \ 0 \ 1 \ 0 \ 1 \ 0 \ 1 \ 0$	Set transfer rate to 24	400 bps.
IMCCLH	$\leftarrow$ 1 1 0 1 0 (	Enable INTTX0 interr	upt and set its priority level to 4.
SCOBUF	← * * * * * * * * *	* Set transmit data.	

Example: To transmit data in the following format, set the control registers as shown below.

Note: X = Don't care; "-" = No change

#### (3) Mode 2 (8-bit UART mode)

Setting the SM1 and SM0 bits of SC0MOD to 10 places the device into 8-bit UART mode. In this mode, a parity bit can be used. Parity can be enabled or disabled using SC0CR $\langle PE \rangle$ . When PE = 1 (parity enabled), even or odd parity can be selected using SC0CR $\langle EVEN \rangle$ .

Example: To transmit data in the following format, set the control registers as shown below.

Note: X = Don't care; "—" = No change

### (4) Mode 3 (9-bit UART mode)

Setting SC0MOD0<SM1:SM0> to 11 places the device into 9-bit UART mode. In this mode a parity bit cannot be used; hence, parity should be disabled by setting SC0CR<PE> to 0.

During transmission the most significant bit (the 9th bit) is written to the TB8 bit of the serial channel mode register SC0MOD0. During reception the bit is stored in the RB8 bit of the serial channel control register SC0CR. Data is always written to or read from the buffer register the most significant bit first and then the rest of the data from SC0BUF. The STOP bit length can be specified using SCnMOD2<SBLEN>.

Wake-up function

In 9-bit UART mode, slave controller wake-up can be enabled by setting SC0MOD0<WU> to 1. An INTRX0 interrupt will only be generated if RB8 = 1.

Note: The slave controller's TXD pin must always be placed in open-drain output mode by setting the ODE register accordingly.

Figure 3.11.41 Serial Link Using the Wake-Up Function

### Protocol

- 1) The master and slave controllers are placed in 9-bit UART mode.
- 2) Each slave controller is enabled for reception by setting SC0MOD0<WU> to 1.
- 3) The master controller transmits one frame of data including the 8-bit slave controller selection code. At this point the most significant bit (bit 8: TB8) is set to 1.

- 4) Each slave controller receives the above frame. The slave controller whose selection code matches the transmitted selection code clears its WU bit to 0.
- 5) The master controller transmits data to the selected slave controller (the one whose SC0MOD0<WU> bit has been cleared to 0). At this point the most significant bit (bit 8: TB8) is set to 0.

6) No interrupt (INTRX0) is generated for the slave controllers whose WU bit remains 1 because the most significant bit of the received data (bit 8: RB8) = 0. These slave controllers ignore the received data. The slave controller whose WU bit has been cleared to 0 can transmit data to the master controller so as to notify the master controller that it has finished receiving.

Example settings: Serial link with two slave controllers using the internal clock  ${\sf f}_{{\sf sys}/{\sf 2}}$  as the transfer clock

### 3.12 Serial Bus Interface (SBI)

The TMP1942 contains one serial bus interface (SBI) channel. The serial bus interface has the following two operating modes:

- I<sup>2</sup>C bus mode (multi-master)
- Clock-synchronous 8-bit SIO mode

In I<sup>2</sup>C bus mode, the serial bus interface can be connected to external devices via PF4 (SDA) and PF5 (SCL). In clock-synchronous 8-bit SIO mode, it can be connected to external devices via PF3 (SCK), PF4 (SO) and PF5 (SI).

The following table shows the pin settings for each mode:

	ODE <odef5, f4=""></odef5,>	PFCR <pf5c, pf3c="" pf4c,=""></pf5c,>	PAFC <pf5f, pf3f="" pf4f,=""></pf5f,>
I <sup>2</sup> C bus mode	11	11X	110
Clock-synchronous 8-bit SIO mode	XX	011 010	111

X: Don't care

### 3.12.1 Configuration

#### 3.12.2 Control

The following registers are used to control the serial bus interface and monitor its operating status:

- Serial bus interface control register 1 (SBI0CR1)
- Serial bus interface control register 2 (SBI0CR2)
- Serial bus interface data buffer register (SBI0DBR)
- I<sup>2</sup>C bus address register (I2C0AR)
- Serial bus interface status register (SBI0SR)
- Serial bus interface status register 0 (SBI0BR0)
- Serial bus interface status register 1 (SBI0BR1)

The functions of the above registers vary according to the current operating mode of the serial bus interface. For details, refer to Section 3.12.4, "Control in I<sup>2</sup>C bus mode", and Section 3.12.7, "Control in clock-synchronous 8-bit SIO mode".

### 3.12.3 I<sup>2</sup>C Bus Mode Data Formats

Figure 3.12.1 shows the serial bus interface data formats used in I<sup>2</sup>C bus mode.

(a) Addressing format

(b) Addressing format (with restart)

(c) Free data format (format used to transfer data from master device to slave device)

Figure 3.12.5 I<sup>2</sup>C Bus Mode Registers

### TOSHIBA

### 3.12.5 Control in I<sup>2</sup>C Bus Mode

(1) Specifying acknowledgment mode

Setting SBI0CR1<ACK> to 1 causes the serial bus interface to operate in acknowledgment mode. When operating as the master device, the device allows one extra clock cycle for an acknowledge signal. In transmitter mode, the device releases the SDA pin during this clock cycle so that it can receive an acknowledge signal from the receiver. In receiver mode, the device pulls the SDA pin Low during this clock cycle, thus generating an acknowledge signal.

Setting SBI0CR1<ACK> to 0 causes the serial bus interface to operate in non-acknowledgment mode, in which case the device will not generate an extra clock cycle for an acknowledge signal.

(2) Selecting the number of bits to be transferred

SBI0CR1<BC2:BC0> can be used to specify the number of bits in the next data item to be transmitted or received.

Since the BC2:BC0 bits are cleared to 000 as a start condition, the slave address and direction bit are always transferred as eight bits. In all other cases, the BC2:BC0 bits hold the value which has been set.

- (3) Serial clock
  - 1) Clock source

The SBI0CR1<SCK2:SCK0> bits are used to select the maximum transfer frequency of the serial clock which is output on the SCL pin in master mode.

Figure 3.12.6 Clock Source

2) Clock synchronization

In  $I^2C$  bus mode, a master device which first pulls the clock line Low will disable the clocks of other master devices which are outputting a High clock pulse, thus implementing wired-AND bus configuration. Therefore, any master which is outputting a High clock pulse must detect the situation and take appropriate action.

Since the serial bus interface has a clock synchronization function, transfers are always performed correctly even when multiple master devices are present on the bus.

The clock synchronization procedure is described below using an example in which there are two masters on the bus.

Figure 3.12.7 Clock Synchronization Example

Master A pulls the internal SCL output Low at point 'a' so that the bus SCL line goes Low. Master B detects this and resets its High-level period count before pulling its internal SCL output Low.

Master A finishes Low-level period counting at point 'b', releasing its internal SCL output back High. However, since master B is still holding the SCL line Low, master A does not start High-level period counting. At point "c", when master B has released its internal SCL output back High and the bus SCL line goes High, master A detects these conditions and starts High-level period counting.

Thus, the bus clock frequency is determined by the master connected to the bus which has the shortest High-level period and the master connected to the bus which has the longest Low-level period.

(4) Setting the slave address and selecting address recognition mode

To operate the device as a slave device, set the slave address in I2C0AR<SA6:SA0> and <ALS>. Setting ALS to 0 selects address recognition mode.

(5) Specifying a master or slave

Setting SBI0CR2<MST> to 1 causes the device to operate as a master device.

Setting SBI0CR2<MST> to 0 causes the device to operate as a slave device. If a stop condition or arbitration lost is detected on the bus, SBI0CR2<MST> is automatically cleared to 0 by hardware.

(6) Selecting a transmitter or receiver

Setting SBI0CR2<TRX> to 1 causes the device to operate as a transmitter. Setting SBI0CR2<TRX> to 0 causes the device to operate as a receiver.

In slave mode,

- when transferring data in addressing format
- when the received slave address is the same as the value set in I2C0AR
- when a general call (all 8 bits of data after a start condition are 0) is received

TRX is set to 1 by hardware when the direction bit ( $R/\overline{W}$ ) sent from the master device is 1 or set to 0 when the direction bit is 0.

In master mode, when acknowledgement is returned from a slave device, TRX changes to 0 by hardware if the transmitted direction bit is 1 or changes to 1 if the transmitted direction bit is 0. When no acknowledgement is returned, TRX remains unchanged.

If a stop condition or arbitration lost is detected on the bus, SBI0CR2<TRX> is automatically cleared to 0 by hardware.

(7) Generating a start/stop condition

When SBIOSR < BB > = 0, writing 1s to SBIOCR2 < MST, TRX, BB, PIN > causes a start condition and 8-bit data to appear on the bus. Ensure that SBIOCR1 < ACK > has been set to 1 beforehand.

When BB = 1, writing 1s to SBI0CR2<MST, TRX, PIN> and a 0 to SBI0CR2<BB> initiates a stop condition output sequence on the bus. Do not change the contents of SBI0CR2<MST, TRX, BB, PIN> until a stop condition has been generated on the bus.

Figure 3.12.9 Generating a Stop Condition

The bus status can be determined by reading SBI0SR<BB>. SBI0SR<BB> is set to 1 (bus busy state) upon the detection of a start condition on the bus or reset to 0 (bus free state) upon the detection of a stop condition.

(8) Requesting interrupt service and canceling requests

When a serial bus interface interrupt request (INTS2) occurs, SBI0CR2<PIN> is reset to 0. The SCL line is held Low while SBI0CR2<PIN> = 0.

PIN is reset to 0 when the device has finished transmitting or receiving one word of data, and set to 1 when data is written to or read from SBI0DBR. There is a delay of tLOW between PIN being set to 1 and the SCL line being released.

In address recognition mode (i.e. when I2C0CR<ALS> = 0), PIN is reset to 0 when the slave address received matches the value set in I2C0AR or when a general call is received (i.e. when the eight data bits after the start condition are all 0). Writing a 1 to SBI0CR2<PIN> in the program sets it to 1; however, writing a 0 to PIN does not clear it to 0.

(9) Serial bus interface operating mode

The SBI0CR2<SBIM1:SBIM0> bits are used to set the operating mode of the serial bus interface. To use the serial bus interface in I<sup>2</sup>C bus mode, set SBI0CR2<SBIM1:SBIM0> to 10. Ensure that the bus is free before switching from this mode to port mode.

(10) Monitoring detection of arbitration lost

Since multi-master operation is possible in  $I^2C$  bus mode (i.e. two or more masters may exist on the bus simultaneously), a procedure for arbitrating among masters contending for bus control is needed in order to guarantee the integrity of data being transferred.

Any attempt to generate a start condition in the bus busy state will result in "arbitration lost"; data is not output on the SCL or SDA line. The data on the SDA line is used for bus arbitration in  $I^2C$  bus mode.

The arbitration procedure is described below using an example in which two masters are residing on the bus simultaneously. Masters A and B output the same data until the bit at point "a", at which point master A outputs a Low signal and master B a High signal. Since the SDA line of the bus has wired-AND configuration, it is pulled Low by master A. When the SCL line goes High at point "b", the slave device latches the SDA line data (i.e. the data output by master A). The data output by master B at this time has no effect and is ignored. This condition of master B is referred to as "arbitration lost". Master B releases the SDA pin so that it will not affect data output by other masters. If more than one master transmits the same first data word, the arbitration procedure will be continued on the next and subsequent words.

Figure 3.12.10 Arbitration Lost

The internal SDA output level for each master is compared with the level of the bus SDA line at the rising edge of the SCL clock. If the levels do not match, it is assumed that arbitration is lost and SBI0SR<AL> will be set to 1.

At this point the SBI0SR<MST,TRX> bits are reset to 00, thus placing the master into slave receiver mode. SBI0SR<AL> is cleared to 0 by writing data to or reading data from SBI0DBR, or by writing data to SBI0CR2.

Figure 3.12.11 Example for Master B (D7A = D7B, D6A = D6B)

(11) Monitoring detection of a slave address match

If the device is operating as a slave device in address recognition mode (I2C0AR<ALS> = 0) and receives a general call or a slave address of the same value as that set in I2C0AR, SBI0SR<AAS> will be set to 1. If I2C0AR<ALS> = 1, SBI0SR<AAS> will be set to 1 upon the reception of the first word. The AAS flag is cleared to 0 by writing data to or reading data from SBI0DBR.

(12) Monitoring detection of a general call

SBI0SR<AD0> is set to 1 when a general call is received (i.e. when the eight data bits after the start condition are all 0) in slave mode, and is reset to 0 when a start or stop condition is detected on the bus.

(13) Monitoring the last bit received

SBI0SR<LRB> holds the value of the SDA line which is latched at the rising edge of the SCL clock. In acknowledgment mode, the value read from SBI0SR<LRB> immediately after an INTS2 interrupt request has been generated is equivalent to the value of the ACK signal.

### (14) Software reset

If the serial bus interface circuit locks due to noise from external sources, it can be initialized using the software reset function.

Writing 10 and then 01 to SBIOCR2<SWRST1:SWRST0> causes a reset signal pulse to be applied to the serial bus interface circuit, initializing it. All control registers and status flags are initialized to their reset values. SBIOCR2<SWRST1:SWRST0> are automatically cleared to 00 upon the initialization of the serial bus interface.

Note: A software reset also resets the selection of the operating mode, causing a transition from  $I^2C$  bus mode to clock-synchronous 8-bit SIO mode.

(15) Serial bus interface data buffer register (SBI0DBR)

Reading received data from and writing transmit data to the serial bus interface circuit are accomplished by reading from and writing to SBI0DBR. In addition, in master mode the slave address and the direction bit are set in this register, after which a start condition is generated.

(16) I<sup>2</sup>C bus address register (I2C0AR)

When the device is operating as a slave device, the I2C0AR $\leq$ SA6:SA0> bits are used to set the slave address. In addition, when I2C0AR $\leq$ ALS> = 0, the device recognizes the slave address output by the master device, and data is sent in addressing format. When I2C0AR $\leq$ ALS> = 1, the device will not recognize the slave address output by the master device, and data will be sent in free format.

(17) Baud rate register (SBI0BR1)

Before the I<sup>2</sup>C bus can be used, the P4EN bit of the baud rate circuit control register (SBI0BR1) must be set to 1.

(18) IDLE2 setting register (SBI0BR0)

The SBI0BR0<I2SBI0> bit enables or disables device operation after the device has entered IDLE mode. This bit must be set before the instruction to enter standby mode is executed.

### 3.12.6 Data Transfer Procedure in I<sup>2</sup>C Bus Mode

(1) Initializing the device

```
First, set SBI0BR1<P4EN> and SBI0CR1<ACK, SCK2:SCK0>. Set SBI0BR1<P4EN> to 1 and clear bits 7-5 and 3 of SBI0CR1 to 0.
```

Next, set the slave address in I2C0AR<SA6:SA0> and set I2C0AR<ALS> to 0 for addressing format.

Then, to initialize the device to slave receiver mode, set SBI0CR2<MST, TRX, BB> to 000, SBI0CR2<PIN> to 1, SBI0CR2<SBIM1:SBIM0> to 10 and clear bits 1 and 0 of SBI0CR2 to 00.

- (2) Generating a start condition and slave address
  - 1) In master mode

Follow the procedure described below to generate a start condition and slave address in master mode:

First, check that the bus is free (SBI0SR $\langle BB \rangle = 0$ ). Next, place the serial bus into acknowledgment mode by setting SBI0CR1 $\langle ACK \rangle$  to 1. Also, write the slave address and direction bit to SBI0DBR.

While SBI0SR $\langle BB \rangle = 0$ , set SBI0CR2 $\langle MST, TRX, BB, PIN \rangle$  to 1111 to generate a start condition on the bus. Then output nine clock pulses on the SCL pin. For the first eight clock pulses, output the slave address and direction bit which have been set in SBI0DBR. Release the SDA line on the ninth clock pulse to receive an acknowledge signal from the slave device.

An INTS2 interrupt request is generated at the falling edge of the ninth clock pulse, resetting SBI0CR2<PIN> to 0. In master mode, the SCL line is held Low while PIN = 0. In addition, only when an acknowledge signal is returned from the slave device, the generation of an INTS2 interrupt request causes SBI0CR2<TRX> to change state according to the transmitted direction bit.

Settings in the main routine

	7 6 5 4 3 2 1 0	
→Reg.	← SBI0SR	
Reg.	← Reg. e 0x20	
if Reg.	≠ 0x00	Check that bus is free.
— Then		
SBI0CR1	$\leftarrow \texttt{X} \texttt{X} \texttt{X} \texttt{1} \texttt{0} \texttt{X} \texttt{X} \texttt{X}$	Select acknowledgement mode.
SBI0DR1	$\times \ \mathtt{X} \ X$	Set slave address and direction for target slave.
SBI0CR2	← 1 1 1 1 1 0 0 0	Generate start condition.

#### Example of INTS2 interrupt routine processing

INTCLR ← 0X34 Processing End of interrupt processing Clear interrupt request.

2) In slave mode

In slave mode a start condition and slave address are received.

The slave address and the direction bit are received from the master device with the first eight clock pulses on the SCL line after the start condition. The start condition is also received from the master device. When a general call or an address identical to the slave address which has been set in I2C0AR is received, the SDA line is pulled Low on the ninth clock pulse to output an acknowledge signal.

An INTS2 interrupt request is generated at the falling edge of the ninth clock pulse, resetting SBI0CR2<PIN> to 0. In slave mode, the SCL line is held Low while PIN = 0.

Figure 3.12.12 Generating a Start Condition and Slave Address

(3) Transferring one word of data

During the INTS2 interrupt processing which takes place after the device has finished transferring one word of data, SBI0SR<MST> is tested to determine whether the device is placed in master mode or slave mode.

1) In master mode (when SBIOSR < MST > = 1)

SBI0SR<TRX> is tested to determine whether the device is a transmitter or a receiver.

#### In transmitter mode (when SBI0SR<TRX> = 1)

SBI0SR<LRB> is tested. If SBI0SR<LRB> = 1, the receiver is not requesting data; therefore, a sequence for generating a stop condition (described later) should be performed to terminate the data transfer.

If SBI0SR<LRB> = 0, the receiver is requesting the next data item. If the next data item to be transferred is 8 bits long, write the transfer data to SBI0DBR. If it is not 8 bits long, set SBI0CR1<BC2:BC0> and SBI0CR1<ACK> before writing the transfer data to SBI0DBR. When data is written to the data buffer register, SBI0CR2<PIN> is set to 1, the serial clock for transferring the next word of data is generated from the input on the SCL pin, and one word of data is output on the SDA pin. When the device has finished transferring data, an INTS2 interrupt request is generated, SBI0CR2<PIN> is reset to 0 and the SCL pin is pulled Low. To transfer more than one word, repeat the above procedure starting from the test of SBI0SR<LRB>.

```
Figure 3.12.13 Example in Which SBI0CR1<BC2:BC0> = 000 and SBI0CR1<ACK> = 1 (Transmitter Mode)
```

In receiver mode (when SBI0SR < TRX > = 0)

If the next data item to be transferred is 8 bits long, write the transfer data to SBI0DBR. If it is not 8 bits long, set SBI0CR1<BC2:BC0> and SBI0CR1<ACK> and then read the received data from SBI0DBR in order to release the SCL line. (The data read out immediately after the transmission of the slave address is undefined.) When data is read from the data buffer register, SBI0CR2<PIN> is set to 1. The serial clock for transferring the next word of data is output on the SCL pin. The SDA pin is pulled Low at the final bit when the acknowledge signal goes Low.

An INTS2 interrupt request is now generated, SBI0CR2<PIN> is reset to 0 and the SCL pin is pulled Low. Each time received data is read from SBI0DBR, a clock pulse for one-word data transfer and an acknowledge signal are output.

To instruct the transmitter to terminate data transmission, set SBI0CR1<ACK> to 0 before reading the data which is one word before the last data to be received. This disables generation of an acknowledge clock pulse for the last data. As part of the processing after the generation of an end-of-transfer interrupt request, set SBI0CR1<BC2:BC0> to 001 and read out data, at which time a clock pulse for one-bit data transfer is generated. Since the master at this time is a receiver, it will hold the bus SDA line High. The transmitter receives this High-level signal as an ACK signal, so that the receiver can request the transmitter to terminate transmission.

As part of the processing after the interrupt request generated upon the completion of receiving this one bit, generate a stop condition to terminate data transfer.

Figure 3.12.15 Terminating Data Transmission in Master Receiver Mode

Example: When receiving data N times

INTS2 interrupt (after transmitting data) 7 6 5 4 3 2 1 0 Set number of bits received and ACK. SBIOCR1 ← X X X X 0 X X X Reg. ← SBI0CBR Read dummy data. End of interrupt INTS2 interrupt (first to (N-2)th data reception) 76543210 ← SBI0DBR Req. Read first to (N-2)th received data. End of interrupt INTS2 interrupt ((N-1)th data reception) 7 6 5 4 3 2 1 0 Disable generation of clock for acknowledge signal. SBIOCR1 ← X X X 0 0 X X X ← SBI0DBR Read (N-1)th received data. Rea. End of interrupt INTS2 interrupt (Nth data reception) 7 6 5 4 3 2 1 0 SBIOCR1  $\leftarrow$  0 0 1 0 0 X X X Generate clock for 1-bit transfer. Read Nth received data. ← SBI0DBR Reg. End of interrupt INTS2 interrupt (after receiving data) Processing for generating stop condition Terminate data transfer. End of interrupt Note: X: Don't care

#### 2) In slave mode (SBI0SR<MST> = 0)

In slave mode, an INTS2 interrupt request is generated when a slave address or general call sent by the master is received, or when the data transfer is completed after a general call is received or the received slave address is found to match the device's address. Also, if the arbitration-lost condition is detected in master mode, the device will operate in slave mode, in which case an INTS2 interrupt request will be generated when the device has finished transferring the word in which the arbitration-lost condition was detected. When an INTS2 interrupt request occurs, SBI0CR2<PIN> is set to 0 and the SCL pin is pulled Low. The SCL pin is released tLOW after data is written to or read from SBI0DBR, or tLOW after SBI0CR2<PIN> is set to 1.

In slave mode, perform the processing which normally needs to be performed in slave mode or any processing which needs to be performed after the device has entered slave mode upon detecting the arbitration-lost condition.

In each case, test SBI0SR<AL, TRX, AAS, AD0> to determine the necessary processing. Table 3.12.1 shows the various slave mode statuses and the necessary processing for each.

Example: When the slave address is matched and the direction bit is 1 in slave receiver mode

```
INTS2 interrupt
```

```
if TRX = 0

Then go to other processing

if AL = 1

Then go to other processing

if AAS = 0

Then go to other processing

SBI0CR1 \leftarrow X X X 1 0 X X X

SBI0DBR \leftarrow X X X X 0 X X X

Note: X: Don't care
```

Set number of bits to be transmitted. Set transmit data.

<trx></trx>	<al></al>	<aas></aas>	<ad0></ad0>	Status	Processing
1	1	1	0	The arbitration-lost condition was detected while the slave address was being sent and the device received a slave address sent by another master for which the direction bit was 1.	Set SBI0CR1 <bc2:bc0> to the number of bits in one word and write the data to be transmitted to SBI0DBR.</bc2:bc0>
	0	1	0	In slave receiver mode, the device received a slave address sent by another master for which the direction bit was 1.	
		0	0	The device has finished sending one data word in slave transmitter mode.	Test SBI0SR <lrb>. If it is set to 1, indicating that the receiver is not requesting the next data item, set SBI0CR2<pin> to 1 and reset <trx> to 0 to release the bus. If SBI0SR<lrb> = 0, indicating that the receiver is requesting the next data item, set SBI0CR1<bc2:bc0> to the number of bits in one word and write the data to be transmitted to SBI0DBR.</bc2:bc0></lrb></trx></pin></lrb>
0	1	1	1/0	The arbitration-lost condition was detected while the slave address was being sent and the device received either a slave address sent by another master for which the direction bit was 0 or a general call.	Read SBI0DBR to set SBI0CR2 <pin> to 1 (a dummy read), or set it by writing a 1 to it.</pin>
		0	0	The arbitration-lost condition was detected while the slave address or data was being sent and the device finished sending the word.	
	0	1	1/0	In slave receiver mode, the device received either a slave address sent by another master for which the direction bit was 0 or a general call.	
		0	1/0	In slave receiver mode, the device has finished receiving one word of data.	Set SBI0CR1 <bc2:bc0> to the number of bits in one word and read the received data from SBI0DBR.</bc2:bc0>

Table 3.12.2	Processing in Slave Mode
--------------	--------------------------

(4) Generating a stop condition

If SBI0SR $\langle BB \rangle = 1$ , set SBI0CR2 $\langle MST, TRX, PIN \rangle$  to 111 and reset SBI0CR2 $\langle BB \rangle$  to 0. The device starts a sequence for outputting a stop condition to the bus. Do not rewrite the contents of SBI0CR2 $\langle MST, TRX, BB, PIN \rangle$  until the stop condition appears on the bus.

Note, however, that if the bus SCL line has been pulled Low by some other device, the device will wait until the SCL line is released High again; when SCL is High again, the device will drive the SDA pin High, thereby generating a stop condition.

Figure 3.12.16 Generating a Stop Condition

#### (5) Restart procedure

Restart is used by a master device to change the direction of transfer with respect to a slave device without terminating data transfer. The following shows how to trigger a restart when the device is operating in master mode.

First, reset SBI0CR2<MST,TRX,BB> to 000 and set SBI0CR2<PIN> to 1 to release the bus. Since at this time the SDA pin is held High and the SCL pin is released, no stop condition is generated on the bus, with the result that the bus appears to other masters to be in busy state still. Then, test SBI0SR<BB> and wait until it becomes 0, confirming that the SCL pin has been released. Next, test SBI0SR<LRB> and wait until it becomes 1, confirming that no other device is pulling the bus SCL line Low. After using the above procedures to confirm that the bus is free, generate a start condition by following the procedure described earlier in (2).

Note, however, that in order to yield the necessary restart set-up time, a wait time of at least  $4.7 \,\mu s$  must be generated by software between the bus free state being confirmed and a start condition being generated.

Note : Please do not carry out the light of <MST>="0" in the state of <MST>="0" (it cannot re-start).

### 3.12.7 Control in clock-synchronous 8-bit SIO mode

The following section describes the registers which are used to control the serial bus interface and to monitor its operating status when it is used in clock-synchronous 8-bit SIO mode

Figure 3.12.19 SIO Mode Registers

- (1) Serial clock
  - 1) Clock source

Clock sources can be selected using SBI0CR1<SCK2:SCK0> as described below.

#### Internal clock

In internal clock mode, one of seven clock source frequencies can be selected. The serial clock is output to external devices on the SCK pin. Note that when a transfer starts, the SCK pin is driven High.

The device has an automatic wait function which works as follows: if an operation to write data (during transmission) or read data (during reception) in a program cannot keep up with the serial clock rate, the device will automatically stop the serial clock and suspend the next shift operation until reading or writing has been completed.

#### External clock (SBI0CR1<SCK2:SCK0> = 111)

A clock signal from an external source input via the SCK pin can be used as the serial clock. To ensure that shift operations will be performed without fail, the High-level and the Low-level durations of the serial clock must satisfy the pulse width conditions given below.

Figure 3.12.21 Maximum Transfer Frequency for External Clock Input

### 2) Edges used for shifting

During transmission data is shifted at the leading edge; during reception data is shifted at the trailing edge.

### Leading-edge shift

Data is shifted at the leading edge of the serial clock (the falling edge of the SCK pin input/output).

### Trailing-edge shift

Data is shifted at the trailing edge of the serial clock (the rising edge of the SCK pin input/output).

Figure 3.12.22 Edges Used for Shifting

#### (2) Transfer mode

SBI0CR1<SIOM1:SIOM0> is used to select the mode of transfer among transmit mode, receive mode and transmit/receive mode.

1) 8-bit transmit mode

After selecting transmit mode in the control register, write transmit data to SBI0DBR.

Transmission is initiated by setting SBI0CR1<SIOS> to 1 after writing transmit data to the data buffer register. The transmit data is transferred from SBI0DBR to the shift register, from which the data is shifted out to the SO pin synchronously with the serial clock, starting with the least significant bit (LSB). Once the transmit data has been transferred from SBI0DBR to the shift register, SBI0DBR becomes empty and generates an INTSBI (buffer empty) interrupt request to request the next transmit data.

If an internal clock is being used, unless the next data item has been set in the data buffer register after the transmission of all 8 bits of data, the device will automatically stop the serial clock and suspend processing. The automatic wait is released when the next transmit data is written into the data buffer register.

If an external clock is being used, data must be written into SBI0DBR before the next data item can be shifted. The transfer rate thus depends on the maximum delay between an interrupt request being generated and data being written into SBI0DBR by an interrupt service routine.

When transmission is started, after the SBI0SR<SIOF> goes High, the SO pin outputs the final bit of the last transferred data until the falling edge of SCK.

To terminate transmission write a 0 to SBI0CR1<SIOS> or a 1 to SBI0CR1<SIOINH> in the interrupt service routine for the INTS2 interrupt. Once SBI0CR1<SIOS> has been cleared, transmission will be terminated when all the data has been output. Check SBI0SR<SIOF> in the program to determine whether transmission has been terminated. SBI0SR<SIOF> is reset to 0 upon the termination of transmission. If SBI0CR1<SIOINH> has been set to 1, transmission will be aborted immediately and SBI0SR<SIOF> cleared to 0.

Furthermore, if an external clock is being used, SBI0CR1<SIOS> must be cleared to 0 before the device can start shifting out the next transmit data. Unless SBI0CR1<SIOS> has been cleared to 0 before the device shifts out the data, dummy data will be transmitted and transmit operation ends.

INTS2 interr	upt									
SBI0DBR	←	Х	Х	Х	Х	Х	Х	Х	Х	Write transmit data.

(b) External clock

Write transmit data

Example: Sample program (MIPS16) that instructs termination of SIO transmission (with external clock)

	ADDIU	r3, r0, 0x04

	ADDIU	r3, r0, 0y00000111	
	STB	r3, (SBI0CR1)	; $\langle SIOS \rangle \leftarrow 0$

Figure 3.12.24 Transmit Data Retention Time When Terminating Transmission

2) 8-bit receive mode

After selecting receive mode in the control register, write a 1 to SBI0CR1<SIOS>, enabling the device to receive data. Data is read into the shift register from the SI pin synchronously with the serial clock, beginning with the least significant bit. When 8 bits of data have been read, the received data is transferred from the shift register to SBI0DBR and an INTS2 (buffer full) interrupt request is generated, requesting that the received data be read out. The received data is read out from SBI0DBR by an interrupt service routine.

If an internal clock is being used, the automatic wait function is activated, halting the serial clock until the receive data is read out from SBI0DBR.

If an external clock is being used, shift operation is synchronized to the externally sourced clock. The maximum transfer rate for external clock operation thus depends on the maximum delay between an interrupt request being generated and the received data being read out.

To terminate reception write a 0 to SBI0CR1<SIOS> or a 1 to SBI0CR1<SIOINH> in the interrupt service routine for the INTS2 interrupt. Once SBI0CR1<SIOS> has been cleared, reception will be terminated when all the received data bits have been written into SBI0DBR. Check SBI0SR<SIOF> in the program to determine whether reception has been terminated. SBI0SR<SIOF> is reset to 0 upon the termination of reception. After confirming that reception has been set to 1, reception will be aborted immediately and SBI0SR<SIOF> cleared to 0. (In that case, the received data is invalid and need not be read out.)

Note: If the transfer mode is changed during receive operation, the contents of SBI0DBR will be lost. If it is necessary to change the transfer mode, first terminate reception (by writing a 0 to SBI0CR1<SIOS>) and read out the last data received.

			7	6	5	4	3	2	1	0	
	SBIOCR1	←	0	1	1	1	0	Х	Х	Х	Select receive mode.
	SBI0CR1	←	1	0	1	1	0	0	0	0	Start reception.
IN	TS2 interr	upt									
	Reg.	←	SI	BIC	DDE	BR					Read received data.

Figure 3.12.25 Receive Mode (example with internal clock)

3) 8-bit transmit/receive mode

After selecting transmit/receive mode in the control register, write the transmit data to SBI0DBR. Then set SBI0CR1<SIOS> to 1, enabling the device to transmit/receive data. Transmit data is output on the SO pin at the falling edge of the serial clock starting with the least significant bit, while the received data is read into the shift register from the SI pin at the rising edge of the serial clock. When 8 bits of data have been read, the received data is transferred from the shift register to SBI0DBR and an INTS2 interrupt request is generated. Use an interrupt service routine to read out the received data from the data buffer register, then write transmit data to the data buffer register. Since SBI0DBR is shared for transmission and reception, always be sure to read out the received data before writing transmit data to the data buffer register.

If an internal clock is being used, the automatic wait function is activated, halting the serial clock until the received data has been read out and the next transmit data has been written into the data buffer register.

If an external clock is being used, since shift operation is synchronized to the externally sourced clock, the received data must be read out and the next transmit data written into the data buffer register before the next shift operation can start. The maximum transfer rate for external clock operation thus depends on the maximum delay between an interrupt request being generated and the received data being read out.

When transmission is started, after the SBI0SR<SIOF> goes High, the SO pin outputs the final bit of the last transferred data until the falling edge of SCK.

To terminate transmission/reception write a 0 to SBI0CR1<SIOS> or a 1 to SBI0CR1<SIOINH> in the interrupt service routine for the INTS2 interrupt. Once SBI0CR1<SIOS> has been cleared, transmission/reception will be terminated when all the received data bits have been written into SBI0DBR. Check SBI0SR<SIOF> in the program to determine whether transmission/reception has been terminated. SBI0SR<SIOF> is reset to 0 upon the termination of transmission/reception. If SBI0CR1<SIOINH> has been set to 1, transmission/reception will be aborted immediately and SBI0SR<SIOF> cleared to 0.

### 3.13 ANALOG/DIGITAL CONVERTER

The TMP1942 contains a 10-bit Half Flash analog/digital converter (A/D converter) with sixteen analog input channels. In addition to normal conversion, the converter supports highest-priority conversion mode, in which continuous conversion can be interrupted by conversion for a specific analog channel. The converter also supports an A/D monitor function, which allows the device to compare the value in the specified conversion result register with the value set in the compare register to determine which is greater. This function enables the device to monitor analog quantities without software intervention.

Figure 3.13.1 shows a block diagram of the A/D converter. The pins for the sixteen analog input channels (AN0-AN15) are also used as input-only port pins and/or key input pins.

Note: When placing the device into IDLE, SLEEP or STOP mode to reduce the device's current consumption, check that the A/D converter has stopped operating before executing the instruction to enter a standby mode. This is necessary because, with some timings, the internal comparator may remain enabled while the device is in a standby mode. When placing the device into SLOW mode, stop the operation of the A/D converter beforehand.

Figure 3.13.1 A/D Converter Block Diagram

### 3.13.1 Control Registers

The A/D converter is controlled by the A/D mode control registers (ADMOD0, ADMOD1, ADMOD2, ADMOD3 and ADMOD4). Also, the A/D conversion results are stored in the sixteen A/D conversion result upper/lower registers: ADREG08H/L to ADREG7FH/L. The results of highest-priority conversion are stored in ADREGSPH/L.

Figure 3.13.2 shows the registers associated with the A/D converter.

- Note 1: When performing A/D conversion using a hardware start resource by setting ADHTG or HADHTG to 1, observe the following procedure: To use an external trigger, first set P5FC<P57F> to 1 (ADTRG) before enabling hardware start. To use an 8-bit timer, first set ADHS or HADHS to 1 to select the use of a timer interrupt. Then, enable hardware start and finally operate the timer to enable A/D conversion to start at constant intervals.
- Note 2: To change the hardware start resource (from an 8-bit timer to external trigger, or vice versa), first perform a software reset before changing the setting.
- Note 3: To stop using an external trigger (ADTRG) to start A/D conversion, first disable hardware start (by setting ADHTG or HADHTG to 0) and then set P5FC<P57F> to 0 to set the pin to a general-purpose port.

Note 1: A/D conversion is executed using the clock selected by the above register. However, if the accuracy of conversion needs to be guaranteed, be sure to choose a conversion clock frequency such that the conversion period is at least 1 μs, that is, 2 MHz or less in terms of A/D conversion clock frequency.

Note 2: Do not change the conversion clock frequency while A/D conversion is in progress. After conversion is completed, wait at least 2 ADCLK cycles before changing the clock frequency.

Figure 3.13.2 A/D Converter Registers (12/12)

### 3.13.2 Functional description

(1) Analog reference voltage

Apply the High-level analog reference voltage to the VREFH pin and the Low-level analog reference voltage to the VREFL pin. VREF is automatically turned on when A/D conversion is started and turned off when conversion is completed, thus preventing IREF from flowing unnecessarily.

### (2) Selecting the analog input channel

The procedure for selecting the analog input channel varies with the A/D converter operating mode.

### (2-1) Analog reference voltage

• Using a fixed analog input channel (ADMOD0<SCAN> = 0)

Choose one of the pins AN0 to AN15 as the analog input channel by setting ADMOD1<ADCH3:ADCH0> to the appropriate value.

• Scanning analog input channels (ADMOD0<SCAN> = 1)

Choose one of the 24 available scan modes by setting ADMOD1<ADCH3:ADCH0> and ADSCN to the appropriate values.

### (2-2) Highest-priority A/D conversion

Choose one of the pins AN0 to AN15 as the analog input channel by setting ADMOD2<HPADCH3:HPADCH0> to the appropriate value.

After a reset, channel-fixed input on the AN0 pin is selected since ADMOD0<SCAN> and ADMOD1<ADCH3:ADCH0> are initialized to 0 and 0000, respectively. The pins other than that used as the analog input channel can be used as ordinary input port pins.

If highest-priority A/D conversion is activated during normal A/D conversion, highest-priority A/D conversion is performed upon the completion of the current conversion cycle. Normal A/D conversion is resumed upon the completion of highest-priority A/D conversion.

Example: When highest-priority A/D conversion for AN15

(ADMOD2<HPADCH3:HPADCH0> = 1111) is activated during repeated scan conversion for channels AN0 to AN3 (ADMOD0<REPEAT:SCAN> = 10 and ADMOD1<ADCH3:ADCH0> = 0011)

(3) Starting A/D conversion

A/D conversion is classified into normal A/D conversion and highest-priority A/D conversion. Normal A/D conversion can be initiated programmatically by setting ADMOD0<ADS> to 1. Highest-priority A/D conversion can be initiated programmatically hv setting ADMOD2<HPADCE> to 1. Normal A/D conversion is performed in one of the four operating modes as specified with ADMOD0<2:1>. Highest-priority A/D conversion is only performed in channel-fixed single conversion mode. A/D conversion can also be activated by a hardware start source, which is specified with ADMOD4<ADHS> for normal A/D conversion and ADMOD4<HADHS> for highest-priority A/D conversion. When the ADHS or HADHS bit is set to 0, A/D conversion is triggered by a falling edge on the ADTRG pin. When the bit is set to 1, normal A/D conversion is triggered by INTTA0 from 8-bit timer 0 and highest-priority A/D conversion is triggered by INTTA1 from 8-bit timer 1. A/D conversion can still be started programmatically if hardware start is enabled.

When normal A/D conversion starts, the normal A/D conversion busy flag (ADMOD0<ADBF>) is set to 1, indicating that normal A/D conversion is in progress. When highest-priority A/D conversion starts, the highest-priority A/D conversion busy flag (ADMOD2<ADBFHP>) is set to 1, indicating that highest-priority A/D conversion is in progress, with the normal A/D conversion busy flag and end flag (EOCFN) holding the values they had before highest-priority A/D conversion starts.

Normal A/D conversion can be restarted by setting ADMOD0<ADS> to 1 during normal A/D conversion. Restarting normal A/D conversion cancels the current conversion. However, if all necessary sampling operations have been completed for the current conversion, the conversion result is stored before A/D conversion is restarted.

If the start of normal A/D conversion using a hardware resource is enabled, normal A/D conversion is restarted when the start condition for the resource is satisfied during normal A/D conversion. The current conversion is cancelled when normal A/D conversion is restarted. However, if all necessary sampling operations have been completed for the current conversion, the conversion result is stored before A/D conversion is restarted.

If ADMOD2<HPADCE> is set to 1 during normal A/D conversion, the result of the current conversion is stored in the conversion result registers, after which highest-priority A/D conversion starts, that is, A/D conversion for the channel specified with ADMOD2<3:0> (channel-fixed single conversion) starts. Once the result of highest-priority conversion is stored in ADREGSP, normal A/D conversion is resumed following the last conversion for which the result was stored.

If the start of highest-priority A/D conversion using a hardware resource is enabled and the start condition for the resource is satisfied during normal A/D conversion, the result of the current conversion is stored in the conversion result registers, after which highest-priority A/D conversion starts, that is, A/D conversion for the channel specified with ADMOD2<3:0> (channel-fixed single conversion) starts. Once the result of highest-priority conversion is stored in ADREGSP, normal A/D conversion is resumed following the last conversion for which the result was stored.

Highest-priority A/D conversion is not restarted even if ADMOD2<HPADCE> is set to 1 during highest-priority A/D conversion.

(4) A/D conversion modes and the A/D conversion completed interrupt

The following four A/D conversion modes are available for normal A/D conversion, as specified with the settings of ADMOD0<2:1>. Highest-priority A/D conversion always operates in channel-fixed single conversion mode regardless of the settings of ADMOD0<2:1>.

- Channel-fixed single conversion mode
- Channel scan single conversion mode
- Channel-fixed repeated conversion mode
- Channel scan repeated conversion mode

#### (4-1) Normal A/D conversion

Use ADMOD0<REPEAT:SCAN> to select the A/D conversion mode. When A/D conversion has been started, ADMOD0<ADBFN> is set to 1. When the specified A/D conversion has been completed, an A/D conversion completed interrupt (INTAD) is generated and ADMOD0<EOCF> is set to 1, indicating that A/D conversion has been completed. If REPEAT = 0, ADBFN is cleared to 0 simultaneously when EOCF is set to 1. If REPEAT = 1, however, conversion continues with ADBFN held to be 1.

(a) Channel-fixed single conversion mode

Channel-fixed single conversion mode is selected by setting ADMOD0<REPEAT:SCAN> to 00.

In this mode, conversion is performed once for a single selected channel. After the conversion has been completed, ADMOD0<EOCF> will be set to 1 and ADMOD0<ADBF> cleared to 0, thereby generating an INTAD interrupt request. EOCF can be cleared to 0 by reading it.

#### (b) Channel scan single conversion mode

Channel scan single conversion mode is selected by setting ADMOD0<REPEAT:SCAN> to 01.

In this mode, conversion is performed once for each selected channel which is scanned. After the scan conversion has been completed, ADMOD0<EOCF> will be set to 1 and ADMOD0<ADBF> cleared to 0, thereby generating an INTAD interrupt request. EOCF can be cleared to 0 by reading it.

#### (c) Channel-fixed repeated conversion mode

Channel-fixed repeated conversion mode is selected by setting ADMOD0<REPEAT:SCAN> to 10.

In this mode, conversion is performed repeatedly for a single selected channel. After the conversion has been completed, ADMOD0<EOCF> will be set to 1. ADMOD0<ADBF>, however, remains at 1 and is not cleared to 0. The timing at which an INTAD interrupt request will be generated depends on the settings of ADMOD0<ITM1:ITM0>, which also determine the timing at which EOCF is set. EOCF can be cleared to 0 by reading it.

If ADMOD0<ITM1:ITM0> = 00, an interrupt request will be generated for each A/D conversion session completed. In that case, the conversion result is always stored in ADREG08. EOCF becomes 1 once the conversion result has been stored.

If ADMOD0<ITM1:ITM0> = 01, an interrupt request will be generated for every fourth A/D conversion session completed. In that case, the conversion results are stored sequentially in registers ADREG08 through ADREG3B. EOCF becomes 1 once the conversion result has been stored in ADREG3B. The next conversion result will be stored in ADREG08 again. EOCF can be cleared to 0 by reading it.

If ADMOD0<ITM1:ITM0> = 10, an interrupt request will be generated for every eighth A/D conversion session completed. In that case, the conversion results are stored sequentially in registers ADREG08 through ADREG7F. EOCF becomes 1 once the conversion result has been stored in ADREG7F. The next conversion result will be stored in ADREG08 again. EOCF can be cleared to 0 by reading it.

The setting of ADMOD0<RI> determines the repeat interval for repeated conversion mode. If ITM1:ITM0 = 00, this bit controls the interval between a single conversion being completed and the next conversion being started. If ITM1:ITM0 = 01, the bit controls the interval between four conversions being completed and the next conversion being started. If ITM1:ITM0 = 10, the bit controls the interval between eight conversions being completed and the next conversion being started.

(d) Channel scan repeated conversion mode

Channel scan repeated conversion mode is selected by setting ADMOD0<REPEAT:SCAN> to 11.

In this mode, conversion is performed repeatedly for selected scanned channels. Each time one scan conversion operation has been completed, ADMOD0<EOCF> will be set to 1, thereby generating an INTAD interrupt request. ADMOD0<ADBF> remains at 1 and is not cleared to 0. EOCF can be cleared to 0 by reading it.

To stop operation in repeat conversion mode (mode (c) or (d)), write a 0 to ADMOD0<REPEAT>. Repeat conversion mode will then be terminated and ADMOD0<ADBF> cleared to 0 as soon as the conversion currently in progress has been completed.

If ADMOD1<I2AD> = 0 and the device enters a standby state (IDLE, SLEEP or STOP mode), the A/D converter will immediately stop operating, even if A/D conversion is in progress. After the device has exited the standby state, if the A/D converter is operating in repeat conversion mode (mode (c) or (d)), A/D conversion will start again from the beginning (the register settings remain the same, status information is initialized and operation is restarted from the beginning); however, if the A/D converter is operating in single conversion mode (mode (a) or (b)), it will not restart conversion operation (it will remain stopped).

#### (4-2) Highest-priority A/D conversion

Highest-priority A/D conversion is only performed in channel-fixed single conversion mode, regardless of the settings of ADMOD0<REPEAT:SCAN>. When the start condition is satisfied, conversion for the channel specified with ADMOD2<HPADCH3:HPADCH0> is performed once. After the conversion has been completed, a highest-priority A/D conversion completed interrupt will be generated, ADMOD2<EOCFHP> set to 1 and <ADBFHP> cleared to 0. The EOCFHP flag can be cleared to 0 by reading it.

Conversion	Interrupt Generation	EOCF Setting Timing	ADBF (After Interrupt	ADMOD0			
Mode	Timing	(*1)	is Generated)	ITM1:0	REPEAT	SCAN	
Channel-fixed single conversion	After conversion has been completed	After conversion has been completed	0		0	0	
Obernal fired	Every time one conversion has been completed	Every time one conversion has been completed	1 (*2)	00			
Channel-fixed repeated conversion	,	Every time four conversions have been completed	1 (*2)	01	1	0	
	Every time eight conversions have been completed	Every time eight conversions have been completed	1 (*2)	10			
Channel scan single conversion	After scan conversion has been completed	After scan conversion has been completed	0		0	1	
Channel scan repeated conversion	Every time one scan conversion has been completed	Every time one scan conversion has been completed	1 (*2)	_	1	1	

Table 3.13.1 Relationship Among A/D Conversion Modes, Interrupt Generation Timing and Flag Operation

(Note\*1) EOCF is cleared when it is read.

(Note\*2) If repeat intervals are used with RI set to 1, ADBF indicates 0 during interval periods.

ADMOD0<RI> can be used to control the time between one scan conversion being completed and the next scan conversion being started (repeat interval). This bit is only effective when REPEAT = 1.

Example: When repeated scan for channels AN0 to AN2 is set

	Repeated scar	Repeated scan conversions when $RI = 0$											
Channel Converted	0	1	2	0	1	2	0						
		First Scan			Third Scan								
	Repeated scar	Repeated scan conversions when RI = 1											
Channel Converted	0	1 1	2	50	1	2	0						
		First Scan		Interval of 8 AD0 clock cycles	С	Second Scan							
Note: If the start conversion	condition for hig	• • •			•								

conversion is started immediately. Since the interval counter continues running during highest-priority A/D conversion, the next scan will start when both of the following conditions are satisfied: an overflow of the interval counter and the completion of highest-priority A/D conversion.

(5) Highest-priority conversion mode

Highest-priority A/D conversion can be performed by interrupting normal A/D conversion. Highest-priority A/D conversion can be started either programmatically by setting ADMOD2<HPADCE> to 1 or by using a hardware resource as specified with ADMOD4<7:6>. If highest-priority A/D conversion is started during normal A/D conversion, the converter first stores the result of the current conversion to the appropriate result register pair, and then performs a single conversion for the channel specified with ADMOD2<3:0>. The result of that conversion is stored in ADREGSP, at which point a highest-priority A/D conversion for which the result was stored. Any condition that triggers highest-priority A/D conversion is ignored while highest-priority A/D conversion is in progress.

For example, suppose channel scan repeated conversion is being performed for AN0 to AN8. If HPADCE is set to 1 during conversion for AN3, the converter will wait for the conversion for AN3

to complete and then perform conversion for the channel specified with HPADC3:HPADC0. After storing the result of that conversion in ADREGSP, the converter resumes channel scan repeated conversion from AN4.

(6) A/D monitor function

Setting ADMOD3<ADOBSV> to 1 enables the A/D monitor function, which generates an A/D monitor interrupt if the value of the conversion result register specified with REGS<3:0> is greater or less (as specified with ADOBIC) than the value of the compare register. This comparison is performed each time the result is stored in the specified conversion result register, and an interrupt is generated if the condition is satisfied. Since the conversion result register used for the A/D monitor function is usually not read in the program, its overrun flag (OVRn) and conversion result register used for the A/D monitor function.

(7) A/D conversion time

Two clock pulses are required for a single A/D conversion. The A/D conversion clock frequency can be selected from among prescaler outputs PHYT0, PHYT1, PHYT2, PHYT4 and PHYT8. To guarantee the accuracy of the conversion, the A/D conversion time must be at least 1  $\mu$ s, that is, 2 MHz or less in terms of A/D conversion clock frequency. The following figure and tables show example settings:

Example: Repeated scan conversion for channels 0 to 2 (ADC clock frequency = 1 MHz)

							@f = 32 MHz
Peripheral	Clock Gear	Prescaler		A/D	Conversion	Time	
Clock Select <fpsel></fpsel>	<gear1:0></gear1:0>	Clock Source <prck1:0></prck1:0>	φΤ0	φT1	φT2	φT4	φT8

4 MHz	Invalid setting	Invalid setting	2 µsec	4 μsec	8 μsec						
2MHz	Invalid setting	2 µsec	4 μsec	8 μsec	16 μsec						

 Table 3.13.3 Example A/D Conversion Settings (2)

Note: The maximum conversion speed, that is, the minimum conversion time this A/D converter can achieve is 2 μs. However, 4 μs is required before the first conversion result can be retrieved from the conversion result register (or a maximum of 5 μs is required depending on the conversion start request timing because of the interface between the system clock and A/D conversion clock). Subsequently, conversion results can be obtained every 2 μs. Therefore, in single conversion mode or highest-priority conversion mode, A/D conversion requires 4 or 5 times the conversion time shown in the above table. In repeated conversion or scan mode, only the first conversion requires 4 or 5 times the table value (a maximum of 4 to 5 μs) but subsequent conversions are performed within the time shown in the table (a maximum of 2 μs). (8) Storing and reading out A/D conversion results

A/D conversion results are stored in A/D conversion result upper/lower registers (ADREG08H/L to ADREG7FH/L).

In channel-fixed repeated conversion mode, A/D conversion results are sequentially stored in ADREG08H/L to ADREG7FH/L. However, if ITM1 and ITM0 specify that an interrupt be generated every time conversion has been completed, conversion results will be stored in ADREG08H/L only. If ITM1 and ITM0 specify that an interrupt be generated every fourth time conversion has been completed, conversion results will be sequentially stored in ADREG08H/L to ADREG08H/L to ADREG08H/L.

Table 3.13.3 shows the relationship between analog input channels and A/D conversion result registers.

Table 3.13.3 Relationship Between Analog Input Channels and A/D Conversion Result Registers

Analog Input Channel	A/D Convers	sion Result Register		
(Port A)	Other than channel-fixed repeated conversion mode	Channel-fixed repeated conversior mode (every eighth time)		
AN0	ADREG08H/L	ADREG08H/L ←		
AN1	ADREG19H/L			
AN2	ADREG2AH/L	↓		
AN3	ADREG3BH/L			
AN4	ADREG4CH/L	↓		
AN5	ADREG5DH/L			
AN6	ADREG6EH/L			
AN7	ADREG7FH/L	ADREG7FH/L —		
AN8	ADREG08H/L	<itm1:0> = 00</itm1:0>		
AN9	ADREG19H/L	ADREG08H/L <itm1:0> = 01</itm1:0>		
AN10	ADREG2AH/L	ADREG08H/L~		
AN11	ADREG3BH/L	ADREG3BH/L		
AN12	ADREG4CH/L	<itm1:0> = 10</itm1:0>		
AN13	ADREG5DH/L	ADREG08H/L~ ADREG7FH/L		
AM14	ADREG6EH/L			
AM15	ADREG7FH/L			

In highest-priority A/D conversion mode, conversion results are always stored in ADREGSPH/L.

(9) Data polling

To process the results of A/D conversion by means of data polling rather than using an interrupt, poll ADMOD0<EOCF>. If this flag is set, the appropriate A/D conversion result register pair contains the conversion result. Check the flag and then, if it is set, read the A/D conversion result registers. To detect an overrun, first read the upper register and then the lower register. The conversion result is valid if OVRn =0 and ADRnRF = 1 in the lower register.

# 3.14 Digital/Analog Converter

This section describes the D/A converter the TMP1942 contains.

# 3.14.1 Features

- Three 10-bit D/A converter channels.
- Each channel contains a full-range buffer amplifier.
- Each channel can be placed in standby state using control registers.

### 3.14.2 Operation

When the OP and REFON bits of the control register DACCNTn are set to 1s, writing output code and the VALID bit to the output register pair DAREGnL/DAREGnH causes the voltage corresponding to the output code to appear on the DAOUTn output pin. The value in the output registers will be reflected in DAOUT only if the VALID bit is set. Therefore, when updating the code, set the VALID bit if 10-bit data has been updated in DAREGnH first and then DAREGnL. Once the VALID bit has been set to 1, the value stored in DAREGnL/H is fetched into the D/A converter as 10-bit data, which will be recognized as code. Setting DACCNTn<OP> to 0 places the DAOUTn output pin into the high-impedance state. Setting DACCNTn<REFON> to 0 enables reduction of current consumption by decreasing Iref.

# 3.15 Key on Wake-up Circuit

### 3.15.1 Overview

- 14 inputs, KEY0 to KEYD, can be used to terminate STOP/SLEEP mode or as an external interrupt. However, all 14 inputs must be set collectively (in the CG block). Whether individual pins are used or not used can be specified separately (KWUPSTn).
- A single interrupt source is available.
- Rising edge, falling edge, High level, or Low level detection can be selected for individual inputs (KWUPSTn).
- The interrupt source is cleared by KWUPCLR in the interrupt handling routine.
- Key input pins have pull-up resistors which can be enabled or disabled by setting bit 0 (PE) of KWUPCNT. Bit 1 (DPE) specifies whether the pull-up resistors are dynamic or static. Pull-up resistors cannot be set individually.

# 3.15.2 Key on wake-up operation

The TMP1942 has 14 key input pins (KEY0 to KEYD). The KWUPEN bit of the IMCGB1 register in the CG specifies whether the key inputs are used to terminate standby mode or as an ordinary interrupt. Setting the bit to 1 causes all of KEY0 to KEYD to be used to terminate standby mode. Use KWUPSTn<KEYnEN> to specify whether to use each key input and KWUPSTn<KEYn1: KEYn0> to specify the active condition for each key input. The key on wake-up circuit detects key inputs and reports the result of detection to the CG IMCGB1 register using an active High signal. Therefore, set the detection level to High level by setting IMCGB1<EMCG51:EMCG50> to 01. Since the result of detection in the CG is also reported to the interrupt controller (INTC) as an active High signal, set the corresponding interrupt to High level-detected in the INTC. Setting IMCGB1<KWUPEN> to 0 (default) causes all of KEY0 to KEYD to be used as ordinary interrupts. In that case, set the detection level to High level to CG need not be set. Also use KWUPSTn to specify whether each key input is used and its active condition. In the interrupt handling routine, write 1010 to KWUPCLR to clear all key interrupts.

Note: If two or more key inputs are detected at different times, the second key input is cleared simultaneously with the first key input if the second key input is detected before the key interrupt clearing sequence in the interrupt handling routine for the first key input. If the second key input is detected after the clearing sequence for the first key input, a key interrupt will be generated again.

# 3.15.3 Pull-up function

Each key input has a pull-up resistor. Setting KWUPCNT<PE> to 1 results in all of KEY0 to KEYD being pulled up. However, any key inputs which have been specified not to be used with KWUPSTn<KEYnEN> will not be pulled up regardless of the setting of this bit.

Setting KWUPCNT<DPE> to 1 selects dynamic pull-up mode, where the key inputs are pulled up only during given periods at a frequency specified with T1S1:T1S0 and T2S1:T2S0. In this mode, current consumed by the key inputs can be reduced. When DPE is set to 0, the key inputs are always pulled up.

- Note1: Procedures for using key inputs in static pull-up mode
  - A) When setting key inputs first after powering up the device
    - 1) Set KWUPCNT (PE = 1, DPE = 0).
    - 2) Set the KWUPSTn<KEYnEN> corresponding to the key inputs to be used to 1.
    - 3) Wait until the pull-up resistors are disabled.
    - 4) Set the active conditions using the KWUPSTn corresponding to the key inputs to be used.
    - 5) Clear the interrupt request using KWUPCLR.
    - 6) Set the CG and INTC (refer to Section 3.4, "Interrupts" for details).
  - B) When modifying the active condition for a key input during operation
    - 1) Disable key interrupts in the INTC (IMC1<18:16> = 000).
    - 2) Modify the active condition for the key input using the corresponding KWUPSTn.
    - 3) Clear the interrupt request using KWUPCLR.
    - 4) Enable key interrupts in the INTC (set IMC1<18:16> to an appropriate level).
  - C) When enabling a key input during operation
    - 1) Disable key interrupts in the INTC (IMC1<18:16> = 000).
    - 2) Set the KWUPSTn<KEYnEN> corresponding to the key input to be used to 1.
    - 3) Wait until the pull-up resistors are disabled.
    - 4) Set the active condition using the KWUPSTn corresponding to the key input to be used.
    - 5) Clear the interrupt request using KWUPCLR.
    - 6) Enable key interrupts in the INTC (set IMC1<18:16> to an appropriate level).
- Note2 : Procedures for using key inputs in dynamic pull-up mode
  - A) When setting key inputs first after powering up the device
    - 1) Set KWUPCNT (PE = 1, DPE = 0, TnSn = desired time).
    - 2) Set the active conditions using the KWUPSTn corresponding to the key inputs to be used.
    - 3) Clear the interrupt request using KWUPCLR.
    - 4) Set the KWUPSTn<KEYnEN> corresponding to the key inputs to be used to 1.
    - 5) Set the CG and INTC (refer to Section 3.4, "Interrupts" for details).
  - B) When modifying the active condition for a key input during operation
    - 1) Disable key interrupts in the INTC (IMC1<18:16> = 000).
    - 2) Modify the active condition for the key input using the corresponding KWUPSTn.
    - 3) Clear the interrupt request using KWUPCLR.
    - 4) Enable key interrupts in the INTC (set IMC1<18:16> to an appropriate level).
  - C) When enabling a key input during operation
    - 1) Disable key interrupts in the INTC (IMC1<18:16> = 000).
    - 2) Set the active condition using the KWUPSTn corresponding to the key input to be used.
    - 3) Clear the interrupt request using KWUPCLR.
    - 4) Set the KWUPSTn<KEYnEN> corresponding to the key input to be used to 1.
    - 5) Enable key interrupts in the INTC (set IMC1<18:16> to an appropriate level).

Note3: Procedures for using key inputs without pull-up resistors

- A) When setting key inputs first after powering up the device
  - 1) Set KWUPCNT (PE = 0, DPE = 0).
  - 2) Set the active conditions using the KWUPSTn corresponding to the key inputs to be used.
  - 3) Clear the interrupt request using KWUPCLR.
  - 4) Set the KWUPSTn<KEYnEN> corresponding to the key inputs to be used to 1.
  - 5) Set the CG and INTC (refer to Section 3.4, "Interrupts" for details).
- B) When modifying the active condition for a key input during operation
  - 1) Disable key interrupts in the INTC (IMC1<18:16> = 000).
  - 2) Modify the active condition for the key input using the corresponding KWUPSTn.
  - 3) Clear the interrupt request using KWUPCLR.
  - 4) Enable key interrupts in the INTC (set IMC1<18:16> to an appropriate level).
- C) When enabling a key input during operation
  - 1) Disable key interrupts in the INTC (IMC1<18:16> = 000).
  - 2) Set the active condition using the KWUPSTn corresponding to the key input to be used.
  - 3) Clear the interrupt request using KWUPCLR.
  - 4) Set the KWUPSTn<KEYnEN> corresponding to the key input to be used to 1.
  - 5) Enable key interrupts in the INTC (set IMC1<18:16> to an appropriate level).

Note: Ensure that fs is operating before attempting to enable dynamic pull-up by setting DPE to 1. If DPE is set to 1 when fs is not operating, key inputs cannot be detected.

		7	6	5	4	3	2	1	0

Key on wake-up control register KWUPCNT

The following illustrates operation in dynamic pull-up mode:

T1		
$\longleftrightarrow$	T2	
	*	

Key inputs are pulled up only during the T1 periods as specified with T1S1: T1S0.

00: 4/fs (125 μs @ fs=32kHz) 01: 8/fs (250 μs @ fs=32kHz) 10: 16/fs (500 μs @ fs=32kHz) 11: 32/fs (1 ms @ fs=32kHz)

Dynamic pull-up is repeated at intervals of T2 as specified with T2S1:T2S0.

00: 128/fs (4 ms @ fs=32kHz) 01: 256/fs (8 m @ fs=32kHz s) 10: 512/fs (16 ms @ fs=32kHz) 11: 1024/fs (32 ms @ fs=32kHz)

# 3.15.4 Detecting Key Inputs and Detection Timing

1) When pull-up resistors are disabled with PE set to 0

KWUPSTn<KEYn1:0> can be used to specify a High level, Low level, rising edge or falling edge as the active condition for key inputs. The active condition for key inputs is constantly monitored.

2) In static pull-up mode with PE set to 1 and DPE set to 0

KWUPSTn<KEYn1:0> can be used to specify a High level, Low level, rising edge or falling edge as the active condition for key inputs. The active condition for key inputs is constantly monitored.

3) In dynamic pull-up mode with PE set to 1 and DPE set to 1

The active condition for each key input (interrupt) is detected one fs clock cycle before the T1 period ends. Only edge detection is supported. Therefore, key input must be asserted for at least a period of T2. In this case, do not set the active condition to a level. There is a delay of up to T2 before detection. The following figure shows an example when the active condition is a falling edge

euge.	Pull-up ←───→

# 3.16 INTB, INTC, INTD, INTE

The TMP1942 supports extended interrupts INTB, INTC, INTD and INTE. These four interrupts are internally ORed and the result is input to the CG and INTC. Therefore, they represent a single interrupt source. You can determine which interrupt has actually occurred by checking the corresponding bits of INTFLG. These flags are cleared when read.

- Can be used to terminate STOP/SLEEP mode (wake-up) or as an external interrupt. When used for wake-up, all four interrupts must be set collectively (in the CG block). Whether individual pins are used or not used can be specified separately (INTnST).
- A single interrupt source is available (INTBCDE).
- Rising edge, falling edge, High level, or Low level detection can be selected for individual inputs (INTnST).
- The interrupt source is cleared by reading INTFLG in the interrupt handling routine.

Note: Setting procedures

A) When setting INT inputs first after powering up the device

1) Set the active conditions using the INTnST corresponding to the interrupt inputs to be used.

2) Clear the interrupt request by reading INTFLG.

3) Set the INTnST<INTnEN> corresponding to the interrupt inputs to be used to 1.

4) Set the CG and INTC (refer to Section 3.4, "Interrupts" for details).

B) When modifying the active condition for an INT input during operation

1) Disable INTBCD interrupts in the INTC (IMC1<26:24> = 000).

2) Modify the active condition for the INT input using the corresponding INTnST.

3) Clear the interrupt request by reading INTFLG.

4) Enable INTBCD interrupts in the INTC (set IMC1<26:24> to an appropriate level).

C) When enabling an INT input during operation

1) Disable INTBCD interrupts in the INTC (IMC1<26:24 > = 000).

2) Set the active condition using the INTnST corresponding to the interrupt input to be used.

3) Clear the interrupt request by reading INTFLG.

4) Set the INTnST<INTnEN> corresponding to the interrupt input to be used to 1.

5) Enable INTBCD interrupts in the INTC (set IMC1<26:24> to an appropriate level).

# 3.17 ROM Correction Function

This section describes the ROM correction function the TMP1942 supports.

The TMP1942, however, only supports the registers used for the ROM correction function. When debugging the ROM correction function, therefore, use the ROM correction circuit only to replace the contents of the registers and check subsequent operation by rewriting data in the appropriate flash memory areas. The mask ROM version of the product supports the full ROM correction function.

### 3.17.1 Features

- Can replace data at four locations: 8 words for each.
- When the PC value or the address generated by the DMAC matches the address stored in an address register (including 5 low-order "don't care" bits), the data from the corresponding ROM correction data register located in RAM will be used in place of the ROM data at that address.
- ROM correction is automatically enabled by setting an address in an address register.
- If it is necessary to correct more than eight words in ROM, for example, when modifying a program, place a instruction for jumping to a RAM address in the data register in RAM so that you can correct data within RAM.

# 3.17.2 Operation

By setting the physical address of a ROM area (including a projected area) in the address register ADDREGn, you can substitute the data from the data register in RAM corresponding to the ADDREGn for the ROM data at that address. Setting an address in ADDREGn automatically enables the ROM correction function. Upon a reset, the entire ROM correction function is disabled. Therefore, to perform ROM correction in the initial routine after the reset process completes, set an address in an appropriate address register. The ROM correction function is enabled for the address register(s) for which an address is set, so that ROM data will be replaced if the address matches with the value of the PC (when the CPU holds bus control) or if it matches with the source or destination address generated by the DMAC (when the DMAC holds bus control). For example, setting addresses in ADDREG0 and ADDREG3 enables ROM correction for the corresponding areas, so that an address match will constantly be monitored for these address registers and if the addresses match, ROM data will be replaced. In that case, ROM correction will not be performed for ADDREG2 and ADDREG4. Although the address registers have bits 31:5, an address match is detected only for A<18:5> to simplify the circuit. Internally, the ROMCS signal which indicates the ROM area and the match detection from the ROM correction circuit are logically ANDed. ROM correction addresses can only be specified on 8-word boundaries (that is, A0 to A4 are 0). This means data is replaced in 32-byte units. To replace only part of 32 bytes, write the same data for the addresses for which no replacement is required.

The following table shows the relationship between ADDREGn and the RAM areas:

Address Register	Corresponding RAM Area
ADDREG0	0xFFFF_BF80 ~ 0xFFFF_BF9F
ADDREG1	0xFFFF_BFA0 ~ 0xFFFF_BFBF
ADDREG2	0xFFFF_BFC0 ~ 0xFFFF_BFDF
ADDREG3	0xFFFF_BFE0 ~ 0xFFFF_BFFF

# 3.18 Timer for Real-Time Clock

The TMP1942 contains a timer for real-time clock.

Using the 32.768-kHz low-frequency clock, the timer implements a time-keeping function by generating interrupts every 0.0625 s, 0.125 s, 0.25 s or 0.50 s.

The timer for real-time clock can operate in any mode in which low-frequency oscillation is enabled. In addition, a real-time clock interrupt can be used to release the device from a standby mode (other than STOP mode). When using a real-time clock interrupt (INTRTC), set the IMCGB3 register in the CG block appropriately.

### 3.18.1 Configuration

Figure 3.18.1 shows a block diagram of the timer for real-time clock.

Figure 3.18.1 Block Diagram of Timer for Real-Time Clock

The timer for real-time clock can be controlled using the timer for real-time clock control register (RTCCR). Figure 3.18.2 shows the functions of this register.

		7	6	5	4	3	2	1	0
RTCCR	Bit symbol		_	_	_	RTCRCLR	RTCSEL1	RTCSEL0	RTCRUN
(0xFFFF_F0A0)	Read/Write	_	_	_		R/W	R	W	R/W
	After Reset	0	_	_		0	0	0	0
	Function	Must always be set to 0.				Clears accumulator 0: Clear 1: Don't care	00: 2 <sup>14</sup> /fs 01: 2 <sup>13</sup> /fs 10: 2 <sup>12</sup> /fs 11: 2 <sup>11</sup> /fs		0: Stop and clear 1: Count
							(	nterrupt gene fs = 32.768 k 00 0.50 s 01 0.25 s 10 0.125 s 11 0.0625	Hz)

The timer for real-time clock has an accumulator which, when set, holds a cumulative count of the timer for real-time clock interrupts which have been generated. If, for example, an interrupt generation cycle of 0.5 second is selected, this register can hold a cumulative count for up to 127.5 seconds.

		Accumulator											
		7	6	5	4	3	2	1	0				
RTCREG	Bit symbol	RUI7	RUI6	RUI5	RUI4	RUI3	RUI2	RUI1	RUI0				
(0xFFFF_F0A4)	Read/Write	R											
	After Reset	0	0	0	0	0	0	0	0				
	Function Accumulate count value												

Each time an INTRTC interrupt is generated, the accumulator is incremented after one cycle of the fs clock. The accumulator must be read in SLOW mode.

An instruction for clearing the accumulator is not accepted within one fs clock cycle after the generation of an INTRTC interrupt. To clear the accumulator, execute two clear accumulator instructions in SLOW mode.

# 3.19 Watchdog Timer (Runaway Detection Timer)

The TMP1942 contains a watchdog timer for the purpose of runaway detection.

When the CPU starts operating erratically (runaway) due to noise or other causes, the watchdog timer (WDT) detects this runaway condition to re-establish a normal condition. Upon detecting a runaway condition, the watchdog timer notifies the CPU by generating a non-maskable interrupt.

Also, output from the watchdog timer can be transmitted to a reset input (internal to the chip) in order to forcibly reset the device.

#### 3.19.1 Configuration

Figure 3.19.1 shows a block diagram of the watchdog timer.

Figure 3.19.1 Watchdog Timer Block Diagram

The watchdog timer consists of a 22-stage binary counter clocked by the system clock fsys/2. Four binary counter outputs are available:  $2^{15}$ ,  $2^{17}$ ,  $2^{19}$  and  $2^{21}$ . Any one of these counter outputs can be selected using WDMOD<WDTP1:WDTP0>, so that when the selected counter output overflows, a watchdog timer interrupt will be generated, as shown in Figure 3.19.2.

Also, it is possible to reset the chip itself when the counter output overflows. In this case, the chip is reset for a period of 22 to 29 states as shown in Figure 3.19.3. When the chip is reset in this way, the watchdog timer is clocked by a clock of fsys, instead of by the afore-mentioned input clock fsys/2. The fsys clock is derived by dividing the high-speed oscillator's clock fC by a clock gear of 8.

Note: Even when the chip is reset by the watchdog timer, the PLLOFF pin is sampled. Thus, the PLLOFF pin must be held at a constant logic level, either High or Low.

# TOSHIBA

#### 3.19.2 Control Registers

The watchdog timer (WDT) can be controlled using two control registers (WDMOD and WDCR).

(1) Watchdog timer mode register (WDMOD)

a. Setting the watchdog timer detection time (WDTP1:WDTP0)

These two bits are used to set the watchdog timer interrupt detection time necessary for detecting a runaway condition. Upon a reset, WDMOD<WDTP1:WDTP0> are initialized to 00. Figure 3.19.4 shows watchdog timer detection times.

b. Enabling/disabling the watchdog timer (WDTE)

Upon a reset, WDMOD<WDTE> is initialized to 1, enabling the watchdog timer.

To disable the watchdog timer, set this bit to 0 and, at the same time, write the disable code (B1H) to the WDCR register. This dual setting ensures that the watchdog timer cannot easily be disabled by a runaway condition.

To re-enable the watchdog timer after it has been disabled, simply set the WDMOD<WDTE> bit to 1.

c. Connecting the watchdog timer output to reset (RESCR)

This bit is used to specify whether or not the CPU itself will be reset upon the detection of a runaway condition. Upon a reset, WDMOD<RESCR> is initialized to 0. When WDMOD<RESCR> = 0, the CPU will not be reset by the watchdog timer output.

#### (2) Watchdog timer control register (WDCR)

This register controls the watchdog timer by disabling the watchdog timer function and clearing the binary counter.

• Disabling the watchdog timer

The watchdog timer can be disabled by setting WDMOD<WDTE> to 0 and then writing the disable code (B1H) to the WDCR register.

 WDMOD
 ←
 0
 Clear WDTE to 0.

 WDCR
 ←
 1
 0
 0
 1
 Write disable code (B1H).

- Enabling the watchdog timer Set WDMOD<WDTE> to 1.
- Clearing the binary counter

Writing the clear code (4EH) to the WDCR register clears the binary counter and restarts counting.

WDCR  $\leftarrow$  0 1 0 0 1 1 1 0 Write clear code (4EH).

Note: Writing the disable code (B1H) causes the binary counter to be cleared.

WDMOD       Bit symbol       WDTE       WDTP1       WDTP0       —       —       I2WDT       RESCR         (0xFFFF_F090)       Read/Write       R/W       R/W       —       —       R/W       I         After Reset       1       0       0       —       —       0       0         Function       Controls       Selects WDT detection       IDLE       1: Transmits       WDT       alw         01: 2 <sup>18</sup> /fsys       01: 2 <sup>18</sup> /fsys       10: 2 <sup>20</sup> /fsys       11: 0perate       1: Operate       wDT       output to chip's internal reset pin         11: 2 <sup>22</sup> /fsys       11: 2 <sup>22</sup> /fsys       11: 2 <sup>22</sup> /fsys       III       IIII       IIIIIIIIIIIIIIIIIIIIIIIIIIIIIIIIIIII

Figure 3.19.5 Watchdog Timer Control Register

### 3.19.3 Functional Description

After the detection time which has been set in WDMOD<WDT1:WDT0>, the watchdog timer generates an interrupt (INTWDT). The binary counter for the watchdog timer must be cleared to zero by software before an INTWDT interrupt can occur. If runaway occurs in the CPU due to noise or other causes, and prevents the CPU from executing the instruction to clear the binary counter, the binary counter will overflow and generate an INTWDT interrupt. This interrupt notifies the CPU that it has gone out of control, so that the CPU can restore itself to a normal condition by executing a program to correct the runaway condition. Also, output from the watchdog timer can be transmitted to the reset pin or other pins of peripheral devices to address the CPU runway condition.

The watchdog timer will start operating as soon as the device has completed its reset sequence.

In SLEEP and STOP modes, the watchdog timer is reset and remains idle. If the bus is free ( $\overline{BUSAK}$  = Low), it will continue to count. In IDLE mode, the WDMOD<I2WDT> setting determines whether the watchdog timer is on or off. Before placing the device into IDLE mode, set WDMOD<I2WDT> as required.

# 4 Electrical Characteristics

# 4.1 Absolute Maximum Ratings

The letter x in equations presented in this chapter represents the cycle period of the fsys clock selected through the programming of the SYSCR1.SYSCK bit. The fsys clock may be derived from either the high-speed or low-speed crystal oscillator. The programming of the clock gear function also affects the fsys frequency. All relevant values in this chapter are calculated with the high-speed (fc) system clock (SYSCR1.SYSCK=0) and a clock gear factor of 1/fc (SYSCR1.GEAR[1:0]=00).

Note : PortC , PortF

Note: Maximum ratings are limiting values of operating and environmental conditions which should not be exceeded under the worst possible conditions. The equipment manufacturer should design so that no maximum rating value is exceeded with respect to current, voltage, power dissipation, temperature, etc. Exposure to conditions beyond those listed above may cause permanent damage to the device or affect device reliability, which could increase potential risks of personal injury due to IC blowup and/or burning.

RxD data hold after SCK rise	t <sub>HSR</sub>	0		0		0		ns	

# 4.9 SBI Timing

## (1) I2C mode

In the table below, the letters x and T represent the fsys and  $\phi$ T0 cycle periods, respectively. The letter n denotes the value of n programmed into the SCK[2:0] (SCL output frequency select) field in the SBI0CR1.

Parameter	Symbol	Equation		Standard Mode fsys = 8 MHz, n = 4		Fast I fsys = 32 M	Unit	
		Min	Max	Min	Max	Min	Max	
SCL clock frequency	t <sub>SCL</sub>	0		0	100	0	400	kHz
Hold time for START condition	<sup>t</sup> HD:STA			4.0		0.6		μS
Low period of the SCL clock (Note 1)	tLOW			4.7		1.3		μS
SCL clock high width	thigh			4.0		0.6		μS
Setup time for a repeated START condition	<sup>t</sup> SU;STA	Software (Note 5)		4.7		0.6		μs
Data hold time(Input)(Note3,4)	<sup>t</sup> HD;DAT			0		0		μS
Data setup time	tSU;DAT			250		100		ns
Setup time for STOP condition	ts∪;sto			4.0		0.6		μS
Bus free time between STOP and START conditions	t <sub>BUF</sub>	Software (Note 5)		4.7		1.3		μs

Note1: SCL clock low width (output) is calculated with (2(n-1)+4)T. Standard mode: 6 µsec @ Typ (fsys = 8 MHz, n = 4) Fast mode: 1.5µsec @ Typ (fsys = 32 MHz, n = 4) Note2: SCL clock high width (output) is caluculated with (2 (n - 1))T. Standard mode: 4 µsec @ Typ (fsys = 8 MHz, n = 4) Fast mode: 1µsec @ Typ (fsys = 32 MHz, n = 4) Note3: The output data hold time is equal to 12X. Note4: The Philips I2C-bus specification states that a device must internally provide a hold time of at least 300 ns for the SDA signal to bridge the undefined region of the fall edge of SCL. However, TMP1942CY/CZ SBI does not satisfy this requirement. Also, the output buffer for SCL does not incorporate slope control of the falling edges; therefore, the equipment manufacturer should design so that the input data hold time shown in the table is satisfied, including tr/tf of the SCL and SDA lines. Note5: Software-dependent. tsc **t**LOW tHIGH SCL SU;STA tSU;DAT tHD;DAT tBUF tsu i SDA Sr S S: START condition Sr: Repeated START condition P; STOP condition Note6: To operate the SBI in I2C Fast mode, the fysy frequency must be no less than 20 MHz. To operate the SBI in I2C Standard mode, the fysy fewquency must be no less than 4 MHz.

(2) Clock-Synchronous 8-Bit SIO Mode

In the tables below, the letters x and T represent the fsys and  $\phi$ T0 cycle periods, respectively. The letter n denotes the value of n programmed into the SCK[2:0] (SCL output frequency select) field in the SBI0CR1.

The electrical specifications below are for an SCK signal with a 50% duty cycle.

3. SCK Input Mode (DVCC51=2.7V~3.6V or 4.5V~5.25V)

Parameter	Symbol	Equation	32 N	Unit		
Farameter	Symbol	Min	Max	Min	Max	Unit
SCK period	tSCY	16x		500		ns
SO data to SCK rise	toss	(t <sub>SCY</sub> /2) - (6x + 30)		34		ns
SO data hold after SCK rise	tons	(t <sub>SCY</sub> /2) + 4x		374		ns
SI data valid to SCK rise	tSRD	0		0		ns
SI data hold after SCK rise	t <sub>HSR</sub>	4x + 10		134		ns

4. SCK Output Mode (DVCC51=2.7V~3.6V or 4.5V~5.25V)

Parameter	Symbol	Equation	32 N	Unit		
Farameter	Symbol	Min	Max	Min	Max	Unit
SCK period (programmable)	tSCY	2 <sup>n</sup> /T		1000		ns
SO data to SCK rise	toss	(t <sub>SCY</sub> /2) – 20		480		ns
SO data hold after SCK rise	t <sub>OHS</sub>	(t <sub>SCY</sub> /2) – 20		480		ns
SI data valid to SCK rise	tSRD	2x + 30		92		ns
SI data hold after SCK rise	t <sub>HSR</sub>	0		0		ns

## 4.10 Event Counters

In the table below, the letter x represents the fsys cycle period.

Parameter	Symbol	Equa	ation	32 N	Unit		
Farameter	Symbol	Min	Max	Min	Max	Unit	
Clock low pulse width	t <sub>VCKL</sub>	2X + 100		163		ns	
Clock high pulse width	t <sub>VCKH</sub>	2X + 100		163		ns	

## 4.11 Timer Capture

In the table below, the letter x represents the fsys cycle period

Parameter	Symbol-	Equa	ation	32N	Unit	
		Min	Max	Min	Max	Onic
Low pulse width	tCPL	2X + 100		163		ns
High pulse width	t <sub>CPH</sub>	2X + 100		163		ns

## 4.12 General Interrupts (INT0 to INTA)

In the table below, the letter x represents the fsys cycle period

Parameter	Symbol	Equa	ation	32 N	Unit	
Falameter	Symbol	Min	Max	Min Max		
Low pulse width for INT0-INTA	t <sub>INTAL</sub>	X + 100		132		ns
High pulse width for INT0–INTA	t <sub>INTAH</sub>	X + 100		132		ns

# 4.13 NMI and STOP/SLEEP Wake-up Interrupts

Parameter	Symbol	Equ	ation	32 N	Unit	
Falameter	Symbol	Min	Max	Min	Max	Unit
Low pulse width for $\overline{\text{NMI}}$ and INT0–INT4	t <sub>INTBL</sub>	100		100		ns
High pulse width for INT0–INT4	t <sub>INTBH</sub>	100		100		ns

## 4.14 SCOUT pin

Parameter	Symbol	Equa	ation	32 N	Unit		
T arameter	Symbol	Min	Max	Min	Max	Onit	
SCOUT high pulse width	tSCH	0.5T – 5		10.6		ns	
SCOUT low pulse width	t <sub>SCL</sub>	0.5T – 5		10.6		ns	

Note: In the above table, the letter T represents the cycle period of the SCOUT output clock.

## TMP1942CY/CZ-373

## 4.15 Bus Request and Bus Acknowledge Signals

Parameter	Symbol	Equ	ation	32 N	Unit	
Falameter	Symbol	Min	Max	Min	Max	Unit
Bus float to BUSAK asserted	t <sub>ABA</sub>	0	80	0	80	ns
Bus float after BUSAK negated	t <sub>BAA</sub>	0	80	0	80	ns

Note 1: If the current bus cycle has not terminated due to wait-state insertion, the TMP1941AF does not respond to **BUSRQ** until the wait state ends.

Note 2: This broken lines indicate that output buffers are disabled, not that the signals are at indeterminate states. The pin holds the last logic value present at that pin before the bus is relinquished. This is dynamically accomplished through external load capacitances. The equipment manufacturer may maintain the bus at a predefined state by means of off-chip resistors, but he or she should design, considering the time (determined by the CR constant) it takes for a signal to reach a desired state. The on-chip, integrated programmable pullup/pulldown resistors remain active, depending on internal signal states.

## 4.16 KWUP

Pull-up Register Inactive

Parameter	Symbol	Equ	ation	32 N	Unit	
Falameter	Symbol	Min	Max	Min	Max	Onit
Low pulse width for KEY0~D	tky <sub>TBL</sub>	100		100		ns
High pulse width for KEY0~D	tky <sub>TBH</sub>	100		100		ns

Static Pull-up

Parameter	Symbol	Equa	ation	32 N	Unit	
Falameter	Symbol	Min	Max	Min	Max	Unit
Low pulse width for KEY0~D	tky <sub>TBL</sub>	100		100		ns

Dynamic Pull-up

Parameter	Svmbol	Equa	ation	32 N	Unit	
i arameter	Зупрог	Min	Max	Min	Max	Onit
Low pulse width for KEY0~D	tky <sub>TBL</sub>	T2+100		T2+100		ns

T2: Dynamic pull-up frequency

# 4.17 2-phase input pulse counter mode

Parameter	Symbol	Equ	ation	32 N	Unit		
Falameter	Symbol	Min	Max	Min Max		Onit	
2-phase input pulse cycle	Tdcyc	8Y		250		μs	
2-phase input set up	Tabs	Y+20		31.27		μs	
2-phase input hold	Tabh	Y+20		31.27		μs	

Y:Sampling clock(fs or fsys/2)

# 4.18 ADTRG Input

Parameter	Symbol	Equati	on	32 N	Unit	
Falameter	Symbol	Min	Max	Min	Min Max	
ADTRG low level pulse width	tadL	fsysy/2+20		51.25		ns
ADTRG high level pulse interval	Tadh	fsysy/2+20		51.25		ns

# 5. I/O Register Summary

The internal I/O registers occupy 8-kbyte addresses from FFFFE000H through FFFFFFFH.

- (1) I/O Ports
- (2) Watchdog Timer (WDT)
- (3) Real-Time Clock (RTC)
- (4) 8-Bit Timer
- (5) 16-Bit Timer
- (6) UART/Serial I/O 0/1 (UART/SIO)
- (7) I2CBUS/Serial I/O (I2C/SIO)
- (8) UART/Serial I/O 3/4/5 (UART/SIO)
- (9) 10-Bit A/D Converter (ADC)
- (10) 10-Bit D/A Converter (DAC)
- (11) Key On Waik up (KWUP)
- (12) Interrupt Controller (INTC)
- (13) DMA Controller (DMAC)
- (14) Chip Select (CS)/Wait Controller
- (15) Clock Generator (CG)
- (16) FLASH
- (17) ROM correction

Table Organization

Mnemonic	Register Name	Address	7	6	Γ	1	0	
					$\left( \right)$			→ Bit Symbol
					lΓ			→ Read/Write
					71			→ Reset Value
					Γ			

<u>Access</u>

- $R/W\ \ :\ \ Read/Write.$  The user can read and write the register bit.
- R  $\therefore$  Read omly.
- W : Write only.
- $W^*$  : The user can read and write the register bit, but a read always returns a value of 1.

# 6. JTAG Interface

The TMP1942FDXB/CYXB processor provides a boundary-scan interface that is compatible with Joint Test Action Group (JTAG) specifications, using the industry-standard JTAG protocol (IEEE Standard 1149.1/D6).

This chapter describes that interface, including descriptions of boundary scanning, the pins and signals used by the interface, and the Test Access Port (TAP).

## 6.1 What Boundary Scanning Is

With the evolution of ever-denser integrated circuits (ICs), surface-mounted devices, double-sided component mounting on printed-circuit boards (PCBs), and buried vias, in-circuit tests that depend upon making physical contact with internal board and chip connections have become more and more difficult to use. The greater complexity of ICs has also meant that tests to fully exercise these chips have become much larger and more difficult to write.

One solution to this difficulty has been the development of *boundary-scan* circuits. A boundary-scan circuit is a series of shift register cells placed between each pin and the internal circuitry of the IC to which the pin is connected, as shown in Figure 6.1.1. Normally, these boundary-scan cells are bypassed; when the IC enters test mode, however, the scan cells can be directed by the test program to pass data along the shift register path and perform various diagnostic tests. To accomplish this, the tests use the four signals described in the next section: **TDI**, **TDO**, **TMS**, **TCK**, **and TRST**.

Figure 6.1.1 JTAG Boundary-scan Cells

## 6.2 Signal Summary

The JTAG interface signals are listed below and shown in Figure 6.2.1.

- TDI JTAG serial data in
- TDO JTAG serial data out
- TMS JTAG test mode select
- TCK JTAG serial clock input
- TRST JTAG test reset input

Figure 6.2.1 JTAG Interface Signals and Registers

The JTAG boundary-scan mechanism (referred to in this chapter as JTAG mechanism) allows testing of the connections between the processor, the printed circuit board to which it is attached, and the other components on the circuit board.

The JTAG mechanism does not provide any capability for testing the processor itself.

## 6.3 JTAG Controller and Registers

The processor contains the following JTAG controller and registers:

- Instruction register
- Boundary-scan register
- Bypass register
- ID Code register
- Test Access Port (TAP) controller

The processor executes the standard JTAG EXTEST operation associated with External Test functionality testing.

The basic operation of JTAG is for the TAP controller state machine to monitor the JTMS input signal. When it occurs, the TAP controller determines the test functionality to be implemented. This includes either loading the JTAG instruction register (IR), or beginning a serial data scan through a data register (DR), listed in Table 6.3.1. As the data is scanned in, the state of the JTMS pin signals each new data word, and indicates the end of the data stream. The data register to be selected is determined by the contents of the Instruction register.

## 6.3.1 Instruction Register

The JTAG Instruction register includes eight shift register-based cells; this register is used to select the test to be performed and/or the test data register to be accessed. As listed in Table 6.3.1, this encoding selects either the Boundary-scan register or the Bypass register or Device Identification register.

Instruction Code (MSB $\rightarrow$ LSB)	Instruction	Selected Data Register			
0000	EXTEST	Boundary Scan Register			
0001	SAMPLE/PRELOAD	Boundary Scan Register			
0010 to 1110	Reserved	Reserved			
1111	BYPASS	Bypass register			

Table 6.3.1 JTAG Instruction Register Bit Encoding

Figure 66.3.1 shows the format of the Instruction register

Figure 66.3.1 Instruction Register

The instruction code is shifted out to the Instruction register from the LSB.

Figure 6.3.2 Instruction Register Shift Direction

#### 6.3.2 Bypass Register

The Bypass register is 1 bit wide. When the TAP controller is in the Shift-DR (Bypass) state, the data on the TDI pin is shifted into the Bypass register, and the Bypass register output shifts to the TDO output pin.

In essence, the Bypass register is a short-circuit which allows bypassing of board-level devices, in the serial boundary-scan chain, which are not required for a specific test. The logical location of the Bypass register in the boundary-scan chain is shown in Figure 6.3.3. Use of the Bypass register speeds up access to boundary-scan registers in those ICs that remain active in the board-level test datapath.

Figure 6.3.3 Bypass Register Operation

#### 6.3.3 Boundary-Scan Register

The Boundary Scan register includes all of the inputs and outputs of the TMP1942 processor, except some analog output and control signals. The pins of the TMP1942 chip can be configured to drive any arbitrary pattern by scanning into the Boundary Scan register from the Shift-DR state. Incoming data to the processor is examined by shifting while in the Capture-DR state with the Boundary Scan register enabled.

The Boundary-scan register is a single, 115-bit-wide, shift register-based path containing cells connected to all input and output pads on the TMP1942 processor.

The TDI input is loaded to the LSB of the Boundary Scan register. The MSB of the Boundary Scan register is retrieved from the JTDO output.

#### 6.3.4 Test Access Port (TAP)

The Test Access Port (TAP) consists of the five signal pins:  $\overline{\text{TRST}}$ , TDI, TDO, TMS, and TCK. Serial test data and instructions are communicated over these five signal pins, along with control of the test to be executed.

As Figure shows, data is serially scanned into one of the three registers (Instruction register, Bypass register, or the Boundary-scan register) from the **TDI** pin, or it is scanned from one of these three registers onto the **TDO** pin.

The TMS input controls the state transitions of the main TAP controller state machine.

The **TCK** input is a dedicated test clock that allows serial JTAG data to be shifted synchronously, independent of any chip-specific or system clocks.

Figure 6.3.4 JTAG Test Access Port

Data on the **TDI** and **TMS** pins is sampled on the rising edge of the **TCK** input clock signal. Data on the **TDO** pin changes on the falling edge of the **TCK** clock signal.

#### 6.3.5 TAP Controller

The processor implements the 16-state TAP controller as defined in the IEEE JTAC specification.

#### 6.3.6 Controller Reset

The TAP controller state machine can be put into Reset state the following:

- assertion of the  $\overline{\text{TRST}}$  signal (Low) resets the TAP controller.
- keeping the TMS input signal asserted through five consecutive rising edges of TCK input.

In either case, keeping TMS asserted maintains the Reset state.

## 6.3.7 TAP Controller

The state transition diagram of the TAP controller is shown in Figure 6.3.5. Each arrow between states is labeled with a 1 or 0, indicating the logic value of TMS that must be set up before the rising edge of TCK to cause the transition.

Figure 6.3.5 TAP Controller State Diagram

The following paragraphs describe each of the controller states. The left vertical column in Figure 6.3.5 is the data column, and the right vertical column is the instruction column. The data column and instruction column reference data register (DR) and instruction register (IR), respectively.

#### • Test-Logic-Reset

When the TAP controller is in the Reset state, the Device Identification register is selected as default. The three most significant bits of the Boundary-scan register are cleared to 0, disabling the outputs.

The controller remains in this state while TMS is high. If TMS is held low while the controller is in this state, then the controller moves to the Run-Test/Idle state.

• Run-Test/Idle

In the Run-Test/Idle state, the IC is put in a test mode only when certain instructions such as a built-in self test (BIST) instruction are present. For instructions that do not cause any activities in this state, all test data registers selected by the current instruction retain their previous states.

The controller remains in this state while TMS is held low. When TMS is high, the controller moves to the Select-DR-Scan state.

• Select-DR-Scan

This is a temporary controller state. Here, the IC does not execute any specific functions.

If TMS is held low when the controller is in this state, then the controller moves to the Capture-DR state. If TMS is held high, the controller moves to the Select-IR-Scan state in the instruction column.

• Select-IR-Scan

This is a temporary controller state. Here, the IC does not execute any specific functions.

If TMS is held low when the controller is in this state, then the controller moves to the Capture-IR state. If TMS is held high, the controller returns to the Test-Logic-Reset state.

• Capture-DR

In this controller state, if the test data register selected by the current instruction on the rising edge of TCK has parallel inputs, then data can be parallel-loaded into the shift portion of the data register. If the test data register does not have parallel inputs, or if data need not be loaded into the selected data register, then the data register retains its previous state.

If TMS is held low while the controller is in this state, the controller moves to the Shift-DR state. If TMS is held high, the controller moves to the Exit1-DR state.

• Shift-DR

In this controller state, the test data register connected between TDI and TDO shifts data one stage forward towards its serial output.

When the controller is in this state, then it remains in the Shift-DR state if TMS is held low, or moves to the Exit1-DR state if TMS is held high.

#### • Exit 1-DR

This is a temporary controller state.

If TMS is held low when the controller is in this state, the controller moves to the Pause-DR state. If TMS is held high, the controller moves to the Update-DR state.

• Pause-DR

This state allows the shifting of the data register selected by the instruction register to be temporarily suspended. Both the instruction register and the data register retain their current states.

When the controller is in this state, then it remains in the Pause-DR state if TMS is held low, or moves to the Exit2-DR state if TMS is held high.

• Exit 2-DR

This is a temporary controller state.

When the controller is in this state, then it returns to the Shift-DR state if TMS is held low, or moves on to the Update-DR state if TMS is held high.

• Update-DR

In this state, data is latched, on the falling edge of TCK, onto the parallel outputs of the data registers from the shift register path. The data held at the parallel output does not change while data is shifted in the associated shift register path.

When the controller is in this state, it moves to either the Run-Test/Idle state if TMS is held low, or the Select-DR-Scan state if TMS is held high.

• Capture-IR

In this state, data is parallel-loaded into the instruction register. The two least significant bits are assigned the values "01". The higher-order bits of the instruction register can receive any design specific values. The Capture-IR state is used for testing the instruction register. Faults in the instruction register, if any exist, may be detected by shifting out the data loaded in it.

When the controller is in this state, it moves to either the Shift-IR state if TMS is low, or the Exit1-IR state if TMS is high.

• Shift-IR

In this state, the instruction register is connected between TDI and TDO and shifts the captured data toward its serial output on the rising edge of TCK.

When the controller is in this state, it remains in the Shift-IR state if TMS is low, or moves to the Exit1-IR state if TMS is high.

#### • Exit 1-IR

This is a temporary controller state.

When the controller is in this state, it moves to either the Pause-IR state if TMS is held low, or the Update-IR state if TMS is held high.

• Pause-IR

This state allows the shifting of the instruction register to be temporarily suspended. Both the instruction register and the data register retain their current states.

When the controller is in this state, it remains in the Pause-IR state if TMS is held low, or moves to the Exit2-IR state if TMS is held high.

• Exit 2-IR

This is a temporary controller state.

When the controller is in this state, it moves to either the Shift-IR state if TMS is held low, or the Update-IR state if TMS is held high.

• Update-IR

This state allows the instruction previously shifted into the instruction register to be output in parallel on the rising edge of TCK. Then it becomes the current instruction, setting a new operational mode.

When the controller is in this state, it moves to either the Run-Test/Idle state if TMS is low, or the Select-DR-Scan state if TMS is high.

Table 6.3.2 shows the boundary scan order of the processor signals.

Table 6.3.2 TMP1942 JTAG Boundary-Scan Ordering

#### 6.4 Instructions for JTAG

This section defines the instructions supplied and the operations that occur in response to those instructions.

#### 6.4.1 The EXTEST Instruction

This instruction is used for external interconnect test, and targets the boundary scan register between TDI and TDO. The EXTEST instruction permits BSR cells at output pins to shift out test patterns in the Update-DR state and those at input pins to capture test results in the Capture-DR state.

Typically, before EXTEST is executed, the initialization pattern is first shifted into the boundary scan register using the SAMPLE/PRELOAD instruction. In the Update-DR state, the boundary scan register loaded with the initialization pattern causes known data to be driven immediately from the IC onto its external interconnects. This eliminates the possibility of bus conflicts damaging the IC outputs. The flow of data through the boundary scan register while the EXTEST instruction is selected is shown in Figure 6.4.1, which follows:

Figure 6.4.1 Test Data Flow While the EXTEST Instruction is Selected

The following steps describe the basic test algorithm of an external interconnect test.

- 1. Initialize the TAP controller to the Test-Logic-Reset state.
- 2. Load the instruction register with SAMPLE/PRELOAD. This causes the boundary scan register to be connected between TDI and TDO.
- 3. Initialize the boundary scan register by shifting in determinate data.
- 4. Then, load the initial test data into the boundary scan register.
- 5. Load the instruction register with EXTEST.
- 6. Capture the data applied to the input pin into the boundary scan register.
- 7. Shift out the captured data while simultaneously shifting in the next test pattern.
- 8. Read out the data in the boundary scan register onto the output pin.

Steps 6 to 8 are repeated for each test pattern.

#### 6.4.2 The SAMPLE/PRELOAD Instruction

This instruction targets the boundary scan register between TDI and TDO. As the instruction's name implies, two functions are performed through use of the SAMPLE/ PRELOAD instruction.

• SAMPLE allows the input and output pads of an IC to be monitored. While it does so, it does not disconnect the system logic from the IC pins. The SAMPLE function occurs in the Capture-DR controller state. An example application of SAMPLE is to take a snapshot of the activity of the IC's I/O pins so as to verify the interaction between ICs during normal functional operation. The flow of data for the SAMPLE phase of the SAMPLE/PRELOAD instruction is shown in Figure 6.4.2.

Figure 6.4.2 Test Data Flow While SAMPLE is Selected

• PRELOAD allows the boundary scan register to be initialized before another instruction is selected. For example, prior to selection of the EXTEST instruction, initialization data is shifted into the boundary scan register using PRELOAD as described in the previous subsection. PRELOAD permits shifting of the boundary scan register without interfering with the normal operation of the system logic. The flow of data for the PRELOAD phase of the SAMPLE/PRELOAD instruction is shown in Figure 6.4.3.

Figure 6.4.3 Test Data Flow While PRELOAD is Selected

#### 6.4.3 The BYPASS Instruction

This instruction targets the bypass register between JTDI and JTDO. The bypass register provides a minimum length serial path through the IC (or between JTDI and JTDO) when the IC is not required for the current test. The BYPASS instruction does not cause interference to the normal operation of the on-chip system logic. The flow of data through the bypass register while the BYPASS instruction is selected is shown in Figure 6.4.4.

## 6.5 Note

This section describes details of JTAG boundary-scan operation that are specific to the processor.

- The DAOUT0, 1, 2, **X2**, and **X1** signal pads do not support JTAG.
- Reset for JTAG
- (1) JTAG circuit is initialized by  $\overline{\text{TRST}}$  assertion. And then deassert  $\overline{\text{TRST}}$ .
- (2) At input to TMS = 1 and asserted for more 5 TCK cycles.

# 7 I/O Port Equivalent-Circuit Diagrams

• How to read circuit diagrams

The circuit diagrams in this chapter are drawn using the same gate symbols as for the 74HCxx Series standard CMOS logic ICs.

The signal named STOP has a unique function. This signal goes active-high if the CPU sets the HALT bit when the STBY[1:0] field in the SYSCR2 register is programmed to 01 (i.e., STOP mode) and the Drive Enable (FRVE) bit in the same register is cleared. If the DRVE bit is set, the STOP signal remains inactive (at logic 0).

- The input protection circuit has a resistor in the range of several tens to several hundreds of ohms.
  - P0(D0 to D7 / AD0 to AD7), P1(D8 to D15 / AD8 to AD15, A8 to A15), P2(A16 to A23, A0 to A7), P92 to P97, PA0 to PA6, PB0 to PB6, PC0 to PC5, PC7, PD0, PD1, PD4, PE1, PE4, PE6, PE7, PF3, PF6

P30(RD), P31(WR), DCLK, PCST3 to PCST0, SDAO / TPC, TDO

■ P32 to P36, P40 to P43

■ P5 (AN0 to AN7)

Input Enable

■ P90, P91, PA7, PB7, PC6, PF1

## TMP1942CY/CZ-398

■ PD6 (XT1), PD7 (XT2)

■ NMI , BW0 to BW1, PLLOFF, RSTPUP

TMP1942CY/CZ-399

■ X1, X2

■ VREFH, VREFL

# 8. Notations, Precautions and Restrictions

## 8.1 Notations and Terms

- (1) I/O register fields are often referred to as <register\_mnemonic>.<field\_name> for the interest of brevity. For example, TRUN.TORUN means the TORUN bit in the TRUN register.
- (2) fc, fs, fsys, state
  - fosc: Clock supplied from the X1 and X2 pins
  - fpll: Clock generated by the on-chip PLL
  - fc: Clock selected by the PLLOFF pin
  - fs: Clock supplied from the XT1 and XT2 pins
  - fgear: Clock selected by the SYSCR1.GEAR[1:0] bits
  - fsys: Clock selected by the SYSCR1.SYSCK bit

The fsys cycle is referred to as a state.

In addition, the clock selected by the SYSCR1.FPSEL bit and the prescaler clock source selected by the SYSCR0.PRCK[1:0] bits are referred to as fperiph and  $\phi$ T0 respectively.

## 8.2 Precautions and Restrictions

(1) Processor Revision Identifier

The Process Revision Identifier (PRId) register in the TX19 core of the TMP1942 contains 0x0000\_2C91.

(2) BW0 to BW1 Pins

The BW0 and BW1 pins must be connected to the DVCC pin to ensure that their signal levels do not fluctuate during chip operation.

(3) Oscillator Warm-Up Counter

If an external crystal is utilized, an interrupt signal programmed to bring the TMP1942 out of STOP mode triggers the on-chip warm-up counter. The system clock is not supplied to the on-chip logic until the warm-up counter expires.

(4) Programmable Pull-up Resistors

When port pins are configured as input ports, the integrated pull-up resistors can be enabled and disabled under software control. The pull-up resistors are not programmable when port pins are configured as output ports.

The relevant port registers are programmed with the data resistor.

(5) External Bus Mastership

The pin states while the bus is granted to an external device are described in Chapter 7, I/O Ports.

(6) Watchdog Timer (WDT)

Upon reset, the WDT is enabled. If the watchdog timer function is not required, it must be disabled after reset. When relevant pins are configured as bus arbitration signals, the I/O peripherals including the WDT can operate during external bus mastership.

(7) A/D Converter (ADC)

The ladder resistor network between the VREFH and VREFL pins can be disconnected under software control. This helps to reduce power dissipation, for example, in STOP mode.

(8) Undefined Bits in I/O Registers

Undefined I/O register bits are read as undefined states. Therefore, software must be coded without relying on the states of any undefined bits.

(9) Notations, Precautions and Restrictions

#### **Overflow Exception #1**

#### Problem:

When an overflow exception is taken, the EPC register might contain an incorrect return address, pointing to the instruction immediately following the one that caused an overflow.

The restart location in the EPC register should be the address of the arithmetic instruction that caused the exception, rather than the following instruction.

		Detects an overflow and writes to EPC.						
		ı 	ı 1		: ↓			
n	Arithmetic Instruction (e.g., ADD)	F	D	Е	М	W		
		I I	1 1 1	, , ,	, ,	I		
n + 4	Next Instruction	   	F	D	Е	М	W	
		1 1	 !	!	1	1		
Instruction Pipeline		, , ,	Dete	cts an in	terrupt. Writes to EPC.			
		1 1 1	1 1 1			· ·		
		1	 	1	1			
EPC Register		   	   	   	n	n + 4		

In the above example, the processor writes address n to the EPC register upon detection of an overflow. However, executing the next instruction generates an interrupt at the same time, causing the processor to rewrite the EPC register with address n+4 in the next cycle.

#### Problem-Causing Situation:

- A) Software uses the ADD, ADDI or SUB instruction in the 32-bit ISA.
- B) The ADD, ADDI or SUB instruction causes an overflow.
- C) Another exception is requested simultaneously with the overflow.

This problem occurs when all of these conditions are true.

#### Workarounds:

- Before returning from the overflow exception handler, determine whether the instruction pointed to by the EPC register caused an overflow.
- Make sure that two arithmetic instructions will not appear consecutively.
- Disable interrupts prior to arithmetic instructions.

You should always use one of these workarounds to avoid this problem.

Note: Toshiba's compiler uses no instructions that could cause an overflow. Therefore, since condition c) above never becomes true, this problem does not occur.

## Overflow Exception #2

#### Problem:

If an overflow exception caused a jump to the exception handler and the first instruction in that exception handler caused another exception, the EPC register should point to the address of the first instruction in the exception handler. However, the EPC register might contain the address that caused the overflow exception.

#### • Problem-Causing Situation:

When, with the instruction pipeline full, an overflow exception was taken at the following sequence of instructions and then the first instruction in the overflow exception handler causes another exception

ADD, ADDI or SUB <= # Instruction that causes an overflow Jump or branch instruction <= # Instruction with a delay slot Delay slot

Note: Toshiba's compiler uses no instructions that could cause an overflow. Therefore, this problem does not occur.

#### Workaround:

Don't place a jump or branch instruction immediately following an instruction that could cause an overflow (ADD, ADDI or SUB).

## LWL and LWR Instructions

#### Problem:

The LWL or LWR instruction might provide incorrect results.

#### • Problem-Causing Situation #1:

- a. The destination of a load instruction (LB, LBU, LH, LHU, LW, LWL or LWR) is identical to that of the LWL or LWR instruction.
- b. The instruction pipeline is full. (The load instruction and the LWL or LWR instruction will be executed consecutively.)
- c. The DMAC is programmed for data cache snooping. Once the load instruction is executed, the DMAC initiates a DMA transaction. After it has been serviced, the LWLor LWR instruction is executed.

This problem occurs when all of these conditions are true.

#### Problem-Causing Situation #2:

- a. The destination of a load instruction (LB, LBU, LH, LHU, LW, LWL or LWR) is identical to that of the LWL or LWR instruction.
- b. The Doze or Halt bit in the Config register is set to 1 immediately before the load instruction.
- c. The instruction pipeline is full. (The load instruction and the LWL or LWR instruction will be executed consecutively.)
- d. After the load instruction is executed, the processor is put in the STOP, SLEEP or IDLE mode.
- e. After an interrupt signaling brings the processor out of the STOP, SLEEP or IDLE mode, the LWL or LWR instruction is executed.

Note: This applies to the case in which an interrupt signaling does not generate an interrupt upon exit from STOP, SLEEP or IDLE mode. In other words, either the IEc bit in the Status register is cleared (interrupts disabled), or if the IEc bit is set, the priority level of the incoming interrupt signaling is lower than the mask level programmed in the CMask field in the Status register. (Exit from STOP, SLEEP or IDLE mode can be accomplished even with such settings.)

This problem occurs when all of these conditions are true.

#### Workarounds:

To use the LWL or LWR instruction,

- 1) Place a NOP between a load instruction and the LWL or LWR instruction, or
- Disable the data cache snooping of the DMAC before the LWL or LWR instruction is executed.
   Also, don't put the processor in STOP, SLEEP or IDLE mode before the LWL or LWR instruction is executed.

#### Overflow Exception When a DSU Probe Is Used

#### Problem:

It looks as if an overflow exception caused a jump to the reset and nonmaskable exception vector address (0xBFC0\_0000).

#### • Problem-Causing Situation:

When an overflow exception occurs, with the processor connected to a DSU probe

Note: Toshiba's compiler uses no instructions that could cause an overflow. Therefore, this problem does not occur.

#### Workaround:

Don't place a jump or branch instruction immediately following an instruction that could cause an overflow (ADD, ADDI or SUB).

## IDLE (Doze) Mode

#### Problem:

A deadlock might occur when returning to normal operating mode from IDLE (Doze) mode.

#### • Problem-Causing Situation:

When the DMAC initiates a DMA transaction with snooping enabled after the Doze bit in the Config register is set and before the CPU clock stops.

#### Workaround:

If snooping is enabled, stop the DMAC before putting the processor in IDLE (Doze) mode.
