Off-Line Current Mode PWM Control Circuit with Undervoltage Lockout

The CS284XA, CS384XA provides all the necessary features to implement off-line fixed frequency current-mode control with a minimum number of external components.

The CS384XA family incorporates a new precision temperature–controlled oscillator with an internally trimmed discharge current to minimize variations in frequency. A precision duty–cycle clamp eliminates the need for an external oscillator when a 50% duty–cycle is used. Duty–cycles greater than 50% are also possible. On board logic ensures that V_{REF} is stabilized before the output stage is enabled. Ion implant resistors provide tighter control of undervoltage lockout.

Other features include low startup current, pulse-by-pulse current limiting, and a high-current totem pole output for driving capacitive loads, such as the gate of power MOSFET. The output is LOW in the off state, consistent with N-channel devices.

The CS384XA series of current-mode control ICs are available in 8 and 14 lead packages for surface mount (SO) applications as well as 8 lead PDIP packages.

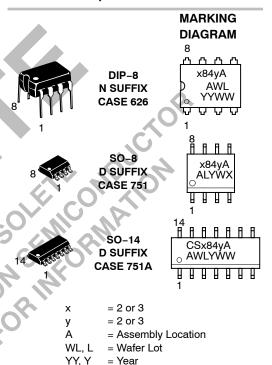

Features

- Optimized for Off-line Control
- Internally Trimmed Temperature Compensated Oscillator
- Maximum Duty-Cycle Clamp
- V_{REF} Stabilized Before Output Stage is Enabled
- Low Startup Current
- Pulse-By-Pulse Current Limiting
- Improved Undervoltage Lockout
- Double Pulse Suppression
- 1.0% Trimmed Bandgap Reference
- High Current Totem Pole Output

CIRCUIT DESCRIPTION

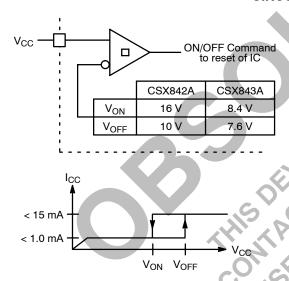

Figure 5. Typical Undervoltage Characteristics

Undervoltage Lockout

During Undervoltage Lockout (Figure 5), the output driver is biased to a high impedance state. The output should be shunted to ground with a resistor to prevent output leakage current from activating the power switch.

PWM Waveform

To generate the PWM waveform, the control voltage from the error amplifier is compared to a current sense signal which represents the peak output inductor current (Figure 6). An increase in $V_{\rm CC}$ causes the inductor current slope to increase, thus reducing the duty cycle. This is an inherent feed–forward characteristic of current mode control, since the control voltage does not have to change during changes of input supply voltage.

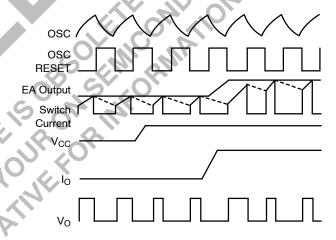

Figure 6. Timing Diagram for Key CS2841B
Parameters

When the power supply sees a sudden large output current increase, the control voltage will increase allowing the duty cycle to momentarily increase. Since the duty cycle tends to exceed the maximum allowed to prevent transformer saturation in some power supplies, the internal oscillator waveform provides the maximum duty cycle clamp as programmed by the selection of oscillator components.

Setting the Oscillator

Oscillator timing capacitor, C_T , is charged by V_{REF} through R_T and discharged by an internal current source. During the discharge time, the internal clock signal blanks out the output to the Low state, thus providing a user selected maximum duty cycle clamp. Charge and discharge times are determined by the formula:

$$\begin{split} t_{C} &= R_{T}C_{T} \ In \bigg(\frac{V_{REF} - V_{lower}}{V_{REF} - V_{upper}} \bigg) \\ t_{d} &= R_{T}C_{T} \ In \bigg(\frac{V_{REF} - I_{d}R_{T} - V_{lower}}{V_{REF} - I_{d}R_{T} - V_{upper}} \bigg) \end{split}$$

Substituting in typical values for the parameters in the above formulas:

$$V_{REF} = 5.0 \text{ V}$$

$$V_{upper} = 2.7 \text{ V}$$

$$V_{lower} = 1.0 \text{ V}$$

$$I_d = 8.3 \text{ mA}$$

$$t_c \approx 0.5534R_TC_T$$

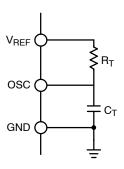

$$t_{d} \, = \, R_{T} C_{T} \, \, \, \text{In} \Big(\frac{2.3 \, - \, 0.0083 R_{T}}{4.0 \, - \, 0.0083 R_{T}} \Big)$$

The frequency and maximum duty cycle can be determined using the Typical Performance Characteristic graphs.

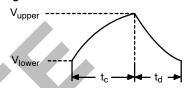

Grounding

High peak currents associated with capacitive loads necessitate careful grounding techniques. Timing and bypass capacitors should be connected close to GND pin in a single point ground.

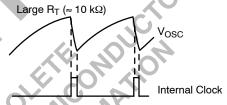

The transistor and $5.0~\text{k}\Omega$ potentiometer, shown in the test circuit, are used to sample the oscillator waveform and apply and adjustable ramp to Sense.
