

The LM78L00 series of 3-terminal positive voltage regula-

tors employ internal current-limiting and thermal shutdown,

making them essentially indestructible. If adequate heat

sinking is provided, they can deliver up to 100 mA output

current. They are intended as fixed voltage regulators in a

wide range of applications including local (on-card) regula-

tion for elimination of noise and distribution problems asso-

ciated with single-point regulation. In addition, they can be

# LM78L00 Series 3-Terminal Positive Voltage Regulators

#### **General Description**

Features

- Output current up to 100 mA
- No external components
- Internal thermal overload protection
- Internal short circuit current-limiting
- Available in JEDEC TO-92
- Output Voltages of 5.0V, 6.2V, 8.2V, 9.0V, 12V, 15V
   Output voltage tolerances of ±5% over the temperature range

\_M78L00 Series 3-Terminal Positive Voltage Regulators

# **Absolute Maximum Ratings**

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications. Storage Temperature Range  $-65^{\circ}$ C to  $+150^{\circ}$ C

Operation Junction Temperature Range Commercial (LM78L00AC) 0°C to + 125°C Lead Temperature TO-92 Package/SO-8 (Soldering, 10 sec.) Power Dissipation Input Voltage 5.0V to 15V ESD Susceptibility

265°C Internally Limited

35V to be determined

# LM78L05AC

# **Electrical Characteristics**

#### **Design Considerations**

The LM78L series regulators have thermal overload protection from excessive power, internal short-circuit protection which limits each circuit's maximum current, and output transistor safe-area protection for reducing the output current as the voltage across each pass transistor is increased.

Although the internal power dissipation is limited, the junction temperature must be kept below the maximum specified temperature ( $125^{\circ}$ C) in order to meet data sheet specifications. To calculate the maximum junction temperature or heat sink required, the following thermal resistance values should be used:

Package	Тур <sup>θ</sup> јс	Max <sup>θ</sup> JC	Тур <sup><i>Ө</i>ЈА</sup>	Max θ <sub>JA</sub>
TO-92			160	160

# **Thermal Considerations**

The TO-92 molded package is capable of unusually high power dissipation due to the lead frame design. However, its thermal capabilities are generally overlooked because of a lack of understanding of the thermal paths from the semiconductor junction to ambient temperature. While thermal resistance is normally specified for the device mounted 1 cm above an infinite heat sink, very little has been mentioned of the options available to improve on the conservatively rated thermal capability.

An explanation of the thermal paths of the TO-92 will allow the designer to determine the thermal stress he is applying in any given application.

# The TO-92 Package

The TO-92 package thermal paths are complex. In addition to the path through the molding compound to ambient temperature, there is another path through the leads, in parallel with the case path, to ambient temperature, as shown in *Figure 1*.

The total thermal resistance in this model is then:

$$\theta_{\rm JA} = \frac{\left(\theta_{\rm JC} + \theta_{\rm CA}\right)\left(\theta_{\rm JL} + \theta_{\rm LA}\right)}{\theta_{\rm JC} + \theta_{\rm CA} + \theta_{\rm JL} + \theta_{\rm LA}} \tag{1}$$

Where:

- $\theta_{JC}$  = thermal resistance of the case between the regulator die and a point on the case directly above the die location.
- $\theta_{CA} =$  thermal resistance between the case and air at ambient temperature.
- $\theta_{JL}$  = thermal resistance from regulator die through the input lead to a point  $1/_{16}$  inch below the regulator case.
- $\theta_{LA}$  = total thermal resistance of the input/output ground leads to ambient temperature.
- $\theta_{JA}$  = junction to ambient thermal resistance.

# Methods of Heat Sinking

With two external thermal resistances in each leg of a parallel network available to the circuit designer as variables, he can choose the method of heat sinking most applicable to his particular situation. To demonstrate, consider the effect of placing a small 72 °C/W flag type heat sink, such as the Staver F1-7D-2, on the LM78L00 molded case. The heat sink effectively replaces the  $\theta_{CA}$  (*Figure 2*) and the new thermal resistance,  $\theta'_{JA}$ , equals 145 °C/W (assuming, 0.125 inch lead length).

The net change of 15 °C/W increases the allowable power dissipation to 0.86W with a minimal inserted cost. A still further decrease in  $\theta_{JA}$  could be achieved by using a heat sink rated at 46 °C/W, such as the Staver FS-7A. Also, if the case sinking does not provide an adequate reduction in total  $\theta_{JA}$ , the other external thermal resistance,  $\theta_{LA}$ , may be reduced by shortening the lead length from package base to mounting medium. However, one point must be kept in mind. The lead thermal path includes a thermal resistance,  $\theta_{SA}$ , from the leads at the mounting point to ambient, that is, the mounting medium.  $\theta_{LA}$  is then equal to  $\theta_{LS} + \theta_{SA}$ . The new model is shown in *Figure 2*.

In the case of a socket,  $\theta_{SA}$  could be as high as 270 °C/W, thus causing a net increase in  $\theta_{JA}$  and a consequent decrease in the maximum dissipation capability. Shortening the lead length may return the net  $\theta_{JA}$  to the original value, but lead sinking would not be accomplished.

In those cases where the regulator is inserted into a copper clad printed circuit board, it is advantageous to have a maximum area of copper at the entry points of the leads. While it would be desirable to rigorously define the effect of PC board copper, the real world variables are too great to allow anything more than a few general observations.

The best analogy for PC board copper is to compare it with parallel resistors. Beyond some point, additional resistors are not significantly effective; beyond some point, additional copper area is not effective.

(2)

Where it is necessary to operate a LM78L00 regulator with a large input/output differential voltage, the addition of series resistor R1 will extend the output current range of the device by sharing the total power dissipation between R1 and the regulator.

$$R1 = \frac{V_{IMin} - V_O - 2.0V}{I_{IMax} + I_O}$$

where:

I<sub>Q</sub> is the regulator quiescent current.

Regulator power dissipation at maximum input voltage and maximum load current is now

$$P_{D Max} = (V_1 - V_0) I_{L Max} + V_1 I_Q$$
 (3) where:

$$V_1 = V_{I \text{ Max}} - (I_{L \text{ Max}} + I_Q) \text{ R1}$$

The presence of R1 will affect load regulation according to the equation:

oad regulation (at constant 
$$V_l$$
) (4)  
= load regulation (at constant  $V_1$ )

+ line regulation (mV per V)  $\times$  (RI)  $\times$  ( $\Delta I_L$ ).

Ŀ

As an example, consider a 15V regulator with a supply voltage of 30  $\pm5.0V$ , required to supply a maximum load current of 30 mA. IQ is 4.3 mA, and minimum load current is to be 10 mA.

$$\mathsf{R1} = \frac{25 - 15 - 2}{30 + 4.3} = \frac{8}{34.3} \approx 240\Omega \tag{5}$$

 $V_1 = 35 - (30 + 4.3) 0.24 = 35 - 8.2 = 26.8V$ 

$$P_{D\;Max}=$$
 (26.8  $-15)$  30  $+26.8$  (4.3)

= 354 + 115

 = 470 mW, which permit operation up to 70°C in most applications.

Line regulation of this circuit is typically 110 mV for an input range of  $25V{-}35V$  at a constant load current; i.e. 11 mV/V.

Load regulation = constant V<sub>1</sub> load regulation (6)  
(typically 10 mV, 10 mA-30 mA 
$$I_L$$
)

 $20 \text{ mA at a constant V}_{I} \text{ of } 30\text{V}.$ 

# **Typical Applications**

TL/H/10051-8

Note 1: To specify an output voltage, substitute voltage value for "00". Note 2: Bypass capacitors are recommended for optimum stability and transient response and should be located as close as possible to the regulator.
