16-Channel Serial to Parallel Converter with High Voltage Backplane Driver and Push-Pull Outputs

Features

- HVCMOS® technology
- Output voltage up to +200V
- Shift register speed 500kHz @ V_{DD} = 1.7V
- 16 high voltage outputs
- High voltage backplane driver
- CMOS input levels

Applications

- Multiple segment EL display
- Piezoelectric transducer driver
- Braille driver

General Description

The HV528 is a 200V, 16-channel serial to parallel converter. The high voltage outputs and the backplane driver are designed to source and sink ±1.0mA.

The high voltage outputs are controlled by a 16-bit serial shift register, followed by a 16-bit latch. Data is shifted through the shift registers during the low to high clock transition. A data output buffer is provided for cascading multiple devices. Data is transferred to the 16-bit latch when a logic level low is applied to the $\overline{LE}$ input. Data is stored in the latch when $\overline{LE}$ is high. Output states are controlled by the data in the latch and by the $\overline{POL}$ pin.

Absolute Maximum Ratings

Parameter	Value
Logic supply, V_{DD}	-0.5V to 7.0V
High voltage supply, V_{PP}	215V
Translator supply voltage, V_{BIAS}	-0.5V to 7.0V
Logic input levels	-0.5V to V_{DD} +0.5V
Operating junction temperature	-40°C to +125°C
Storage temperature range	-65°C to +150°C

Absolute Maximum Ratings are those values beyond which damage to the device may occur. Functional operation under these conditions is not implied. Continuous operation of the device at the absolute rating level may affect device reliability. All voltages are referenced to device ground.

V_{IH}	High-level input voltage	$0.9V_{DD}$	-	V_{DD}	V	---
V_{IL}	Low-level input voltage	0	-		V	---
T_A	Operating temperature	0	-	+70	°C	---

Notes:

1. *External ground noise reduction circuit will be provided by design upon characterization.*

Power-up sequence should be the following*:

1. Apply ground
2. Apply V_{DD}
3. Set all inputs (D_{IN}, CLK, $\overline{LE}$, $\overline{POL}$) to a known state
4. Apply V_{BIAS}
5. Apply V_{PP}

Power-down sequence should be the reverse of the above

*This power up sequence requires an external high voltage diode between V_{DD} and V_{PP}. Without the diode, power up V_{PP} to a V_{DD} level first to bias the silicon substrate. After all other signals are powered, finish raising the V_{PP} to its final level.

V_{BIAS} SUPPLY

The V_{BIAS} supply operates from 5.4 to 6.6V. It is the gate drive voltage for all of the output N-channel MOSFETs. This allows the output peak current sink to be set by varying the V_{BIAS} voltage. A higher V_{BIAS} voltage will increase the current sinking capability.

The operating V_{DD} range is 1.7 to 5.5V. A plot showing the typical characteristics of I_{SINK} vs V_{BIAS} is shown below.
