Synchronous DRAM Module

MT18LSDF6472 – 512MB

For the latest data sheet, refer to Micron's Web site: www.micron.com/products/modules

Features

- 168-pin, dual in-line memory module (DIMM)
- PC133-compliant
- Registered inputs with one-clock delay
- Phase-lock loop (PLL) clock driver to reduce loading
- Utilizes 133 MHz SDRAM components
- Supports ECC error detection and correction
- 512MB (64 Meg x 72)
- Single +3.3V power supply
- Fully synchronous; all signals registered on positive edge of PLL clock
- Internal pipelined operation; column address can be changed every clock cycle
- Internal SDRAM banks for hiding row access/ precharge
- Programmable burst lengths: 1, 2, 4, 8, or full page
- Auto precharge, includes concurrent auto precharge
- Auto refresh mode
- Self refresh mode: 64ms, 8,192-cycle refresh
- LVTTL-compatible inputs and outputs
- Serial presence-detect (SPD)
- Gold edge contacts

Table 1: Timing Parameters
CL = CAS (READ) latency

Module Marking	Clock Frequency	Access Time		Setup Time	Hold Time
		CL = 2	CL = 3		
-13E	133 MHz	5.4ns	–	1.5	0.8
-133	133 MHz	–	5.4ns	1.5	0.8

Figure 2: 168-Pin DIMM Pin Locations

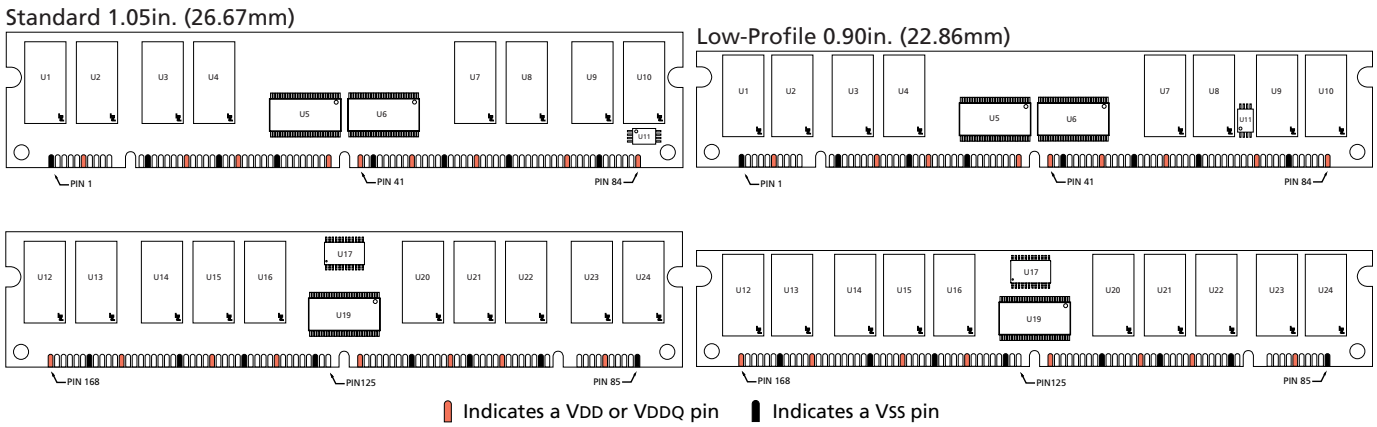

Table 5: Pin Descriptions

Pin numbers not listed in correct order; for more information, see Pin Assignment tables on page 3

Pins	Symbol	Type	Description
27, 111, 115	WE#, CAS#, RAS#	Input	Command inputs: WE#, CAS#, and RAS# (along with S#) define the command being entered.
42	CK0	Input	Clock: CK is distributed through an on-board PLL to all devices.
128	CKE0	Input	Clock enable: CKE activates (HIGH) and deactivates (LOW) the CK signal. Deactivating the clock provides POWER-DOWN and SELF REFRESH operation (all device banks idle) or CLOCK SUSPEND operation (burst access in progress). CKE is synchronous except after the device enters power-down and self refresh modes, where CKE becomes asynchronous until after exiting the same mode. The input buffers, including CKE, are disabled during power-down and self refresh modes, providing low standby power.
30, 45	S0#, S2#	Input	Chip select: S# enables (registered LOW) and disables (registered HIGH) the command decoder. All commands are masked when S# is registered HIGH. S# is considered part of the command code.
28, 29, 46, 47, 112, 113, 130, 131	DQMB0–DQMB7	Input	Input/Output mask: DQMB is an input mask signal for write accesses and an output enable signal for read accesses. Input data is masked when DQMB is sampled HIGH during a WRITE cycle. The output buffers are placed in a High-Z state (two-clock latency) when DQMB is sampled HIGH during a READ cycle.
39, 122	BA0, BA1	Input	Bank address: BA0 and BA1 define to which device bank the ACTIVE, READ, WRITE, or PRECHARGE command is being applied.
33–38, 117–121, 123, 126	A0–A12	Input	Address inputs: Provide the row address for ACTIVE commands, and the column address and auto precharge bit (A10) for READ/WRITE commands, to select one location out of the memory array in the respective device bank. A10 sampled during a PRECHARGE command determines whether the PRECHARGE applies to one device bank (A10 LOW, device bank selected by BA0, BA1) or all device banks (A10 HIGH). The address inputs also provide the op-code during a MODE REGISTER SET command. BA0 and BA1 define which mode register (mode register or extended mode register) is loaded during the LOAD MODE REGISTER command.
83	SCL	Input	Serial clock for presence-detect: SCL is used to synchronize the presence-detect data transfer to and from the module.
166, 167, 168	SA0–SA2	Input	Presence-Detect address inputs: These pins are used to configure the presence-detect device.
147	REGE	Input	Register enable.
2–5, 7–11, 13–17, 19, 20, 55–58, 60, 65–67, 69–82, 74–77, 86–89, 91–95, 97–101, 103, 104, 139–142, 144, 149–151, 153–156, 158–161	DQ0–DQ63	Input/ Output	Data I/Os: Data bus.
21, 22, 52, 53, 105, 106, 136, 137	CB0–CB7	Input/ Output	ECC check bits.
82	SDA	Input/ Output	Serial presence-detect data: SDA is a bidirectional pin used to transfer addresses and data into and data out of the presence-detect portion of the module.

Table 5: Pin Descriptions

Pin numbers not listed in correct order; for more information, see Pin Assignment tables on page 3

Pins	Symbol	Type	Description
6, 18, 26, 40, 41, 49, 59, 72, 84, 90, 102, 110, 124, 133, 143, 157, 168	VDD	Supply	Power supply: +3.3V ±0.3V.
1, 12, 23, 32, 43, 54, 64, 68, 78, 85, 96, 107, 116, 127, 138, 148, 152, 162	VSS	Supply	Ground.
24, 25, 31, 44, 48, 50, 51, 61, 62, 63, 79, 80, 81, 108, 109, 114, 125, 129, 132, 134, 135, 145, 146, 163, 164	NC	–	Not connected: These pins are not connected on this module.

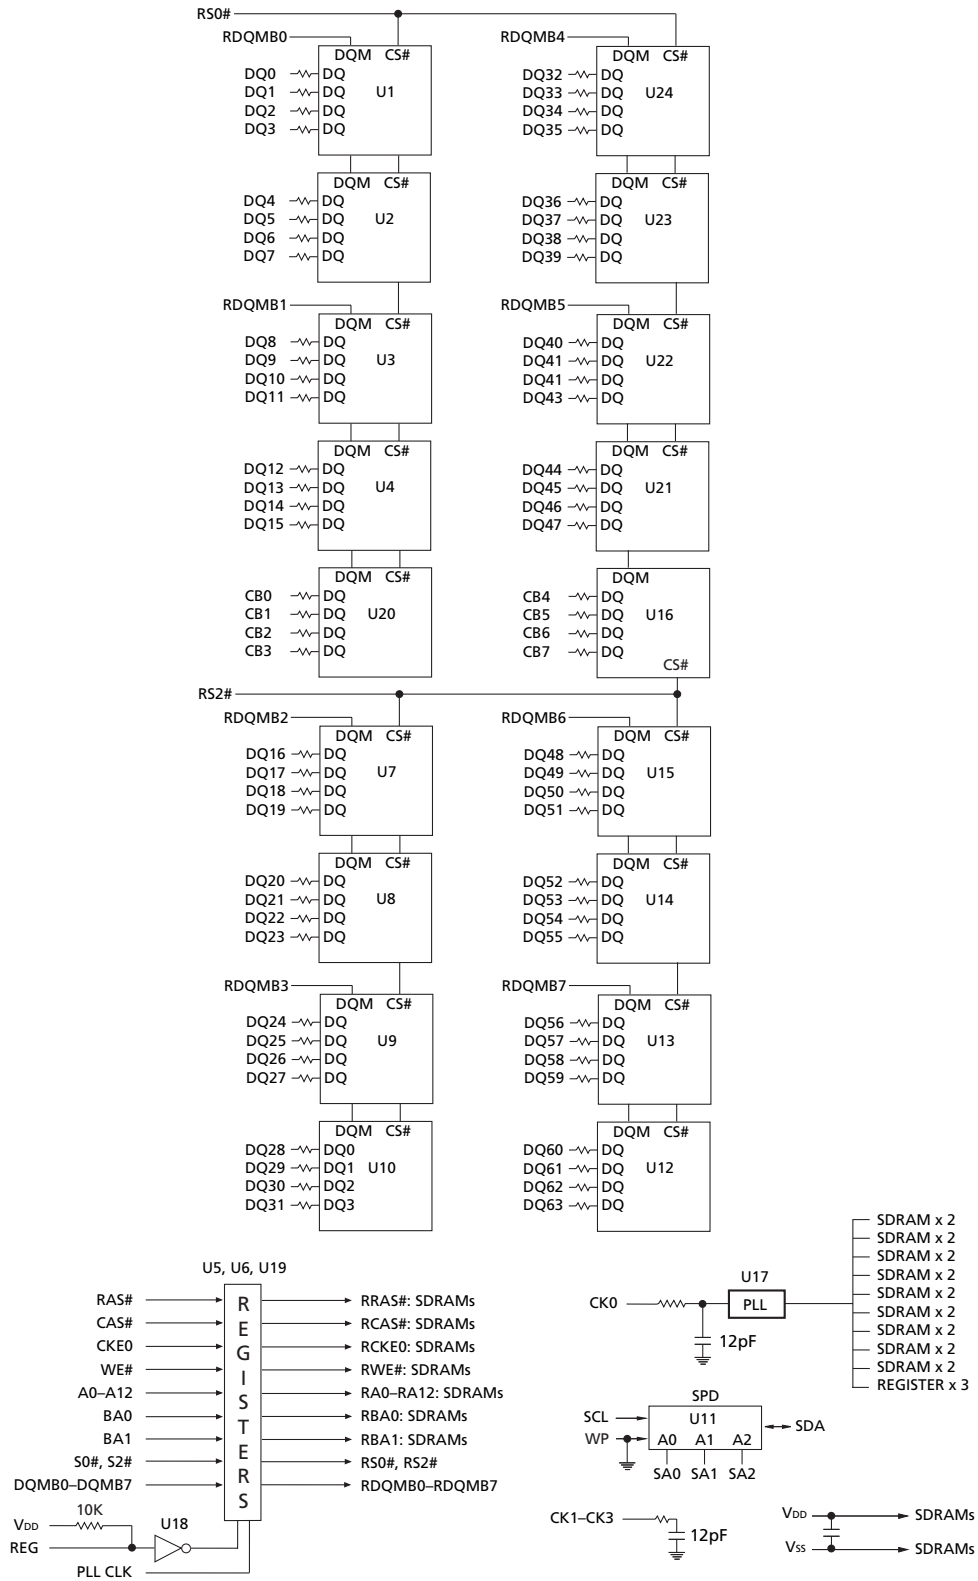
Functional Block Diagram

Per industry standard, Micron modules utilize various component speed grades, as referenced in the module part number guide at www.micron.com/support/numbering.html.

Standard modules use the following SDRAM devices: MT48LC64M4A2FB (512MB).

Lead-free modules use the following SDRAM devices: MT48LC64M4A2BB (512MB).

Figure 3: Functional Block Diagram



Note: All resistor values are 10Ω unless otherwise specified.

General Description

The MT18LSDF6472 is a high-speed CMOS, dynamic random-access, 512MB memory module organized in a x72 (ECC) configuration. This module uses internally configured quad-bank SDRAMs with a synchronous interface (all signals are registered on the positive edge of the clock signal).

Read and write accesses to SDRAM modules are burst oriented; accesses start at a selected location and continue for a programmed number of locations in a programmed sequence. Accesses begin with the registration of an ACTIVE command, which is then followed by a READ or WRITE command. The address bits registered coincident with the ACTIVE command are used to select the device bank and row to be accessed (BA0, BA1 select the device bank; A0–A12 select the device row). The address bits registered coincident with the READ or WRITE command are used to select the starting device column location for the burst access.

SDRAM modules provide for programmable read or write BL of 1, 2, 4, or 8 locations, or full page, with a burst terminate option. An auto precharge function may be enabled to provide a self-timed row precharge that is initiated at the end of the burst sequence.

SDRAM modules use an internal pipelined architecture to achieve high-speed operation. This architecture is compatible with the 2*n* rule of prefetch architectures, but it also allows the device column address to be changed on every clock cycle to achieve a high-speed, fully random access. Precharging one device bank while accessing one of the other three device banks will hide the PRECHARGE cycles and provide seamless, high-speed, random-access operation.

SDRAM modules are designed to operate in +3.3V ±0.3V, low-power memory systems. An auto refresh mode is provided, along with a power-saving, power-down mode. All inputs and outputs are LVTTL-compatible.

SDRAM modules offer substantial advances in DRAM operating performance, including the ability to synchronously burst data at a high data rate with automatic column-address generation, the ability to interleave between device banks in order to hide precharge time, and the capability to randomly change device column addresses on each clock cycle during a burst access. For more information regarding SDRAM operation, refer to the 256Mb SDRAM component data sheet.

PLL and Register Operation

SDRAM modules can be operated in either registered mode (REGE pin HIGH), where the control/address input signals are latched in the register on one rising clock edge and sent to the SDRAM devices on the following rising clock edge (data access is delayed by one clock), or in buffered mode (REGE pin LOW) where the input signals pass through the register/buffer to the SDRAM devices on the same clock. A phase-lock loop (PLL) on the modules is used to redrive the clock signals to the SDRAM devices to minimize system clock loading (CK0 is connected to the PLL, and CK1, CK2, and CK3 are terminated).

Serial Presence-Detect Operation

SDRAM modules incorporate serial presence-detect (SPD). The SPD function is implemented using a 2,048-bit EEPROM. This nonvolatile storage device contains 256 bytes. The first 128 bytes can be programmed by Micron to identify the module type and various SDRAM organizations and timing parameters. The remaining 128 bytes of storage are available for use by the customer. System READ/WRITE operations between the master (system logic) and the slave EEPROM device (DIMM) occur via a standard I^2C

bus using the DIMM's SCL (clock) and SDA (data) signals, together with SA (2:0), which provide eight unique DIMM/EEPROM addresses. Write protect (WP) is tied to ground on the module, permanently disabling hardware write protect.

Initialization

SDRAMs must be powered up and initialized in a predefined manner. Operational procedures other than those specified may result in undefined operation. Once power is applied to VDD and VDDQ (simultaneously) and the clock is stable (stable clock is defined as a signal cycling within timing constraints specified for the clock pin), the SDRAM requires a 100µs delay prior to issuing any command other than a COMMAND INHIBIT or NOP. Starting at some point during this 100µs period and continuing at least through the end of this period, Command Inhibit or NOP commands should be applied.

Once the 100µs delay has been satisfied with at least one Command Inhibit or NOP command having been applied, a PRECHARGE command should be applied. All device banks must then be precharged, thereby placing the device in the all banks idle state.

Once in the idle state, two AUTO refresh cycles must be performed. After the AUTO refresh cycles are complete, the SDRAM is ready for mode register programming. Because the mode register will power up in an unknown state, it should be loaded prior to applying any operational command.

Mode Register Definition

The mode register is used to define the specific mode of operation of the SDRAM device. This definition includes the selection of BL, a burst type, CL, an operating mode and a write burst mode, as shown in the Mode Register Definition Diagram. The mode register is programmed via the LOAD MODE REGISTER command and will retain the stored information until it is programmed again or the device loses power.

Mode register bits M0–M2 specify BL, M3 specifies the type of burst (sequential or interleaved), M4–M6 specify CL, M7 and M8 specify the operating mode, M9 specifies the write burst mode, and M10 and M11 are reserved for future use. A12 (M12) is undefined, but should be driven LOW during loading of mode register.

The mode register must be loaded when all device banks are idle, and the controller must wait the specified time before initiating the subsequent operation. Violating either of these requirements will result in unspecified operation.

Burst Length

Read and write accesses to the SDRAM are burst oriented, with the BL being programmable, as shown in Figure 4 on page 9. BL determines the maximum number of column locations that can be accessed for a given READ or WRITE command. BL of 1, 2, 4, or 8 locations are available for both the sequential and the interleaved burst types, and a full-page burst is available for the sequential type. The full-page burst is used in conjunction with the BURST TERMINATE command to generate arbitrary BL.

Reserved states should not be used, as unknown operation or incompatibility with future versions may result.

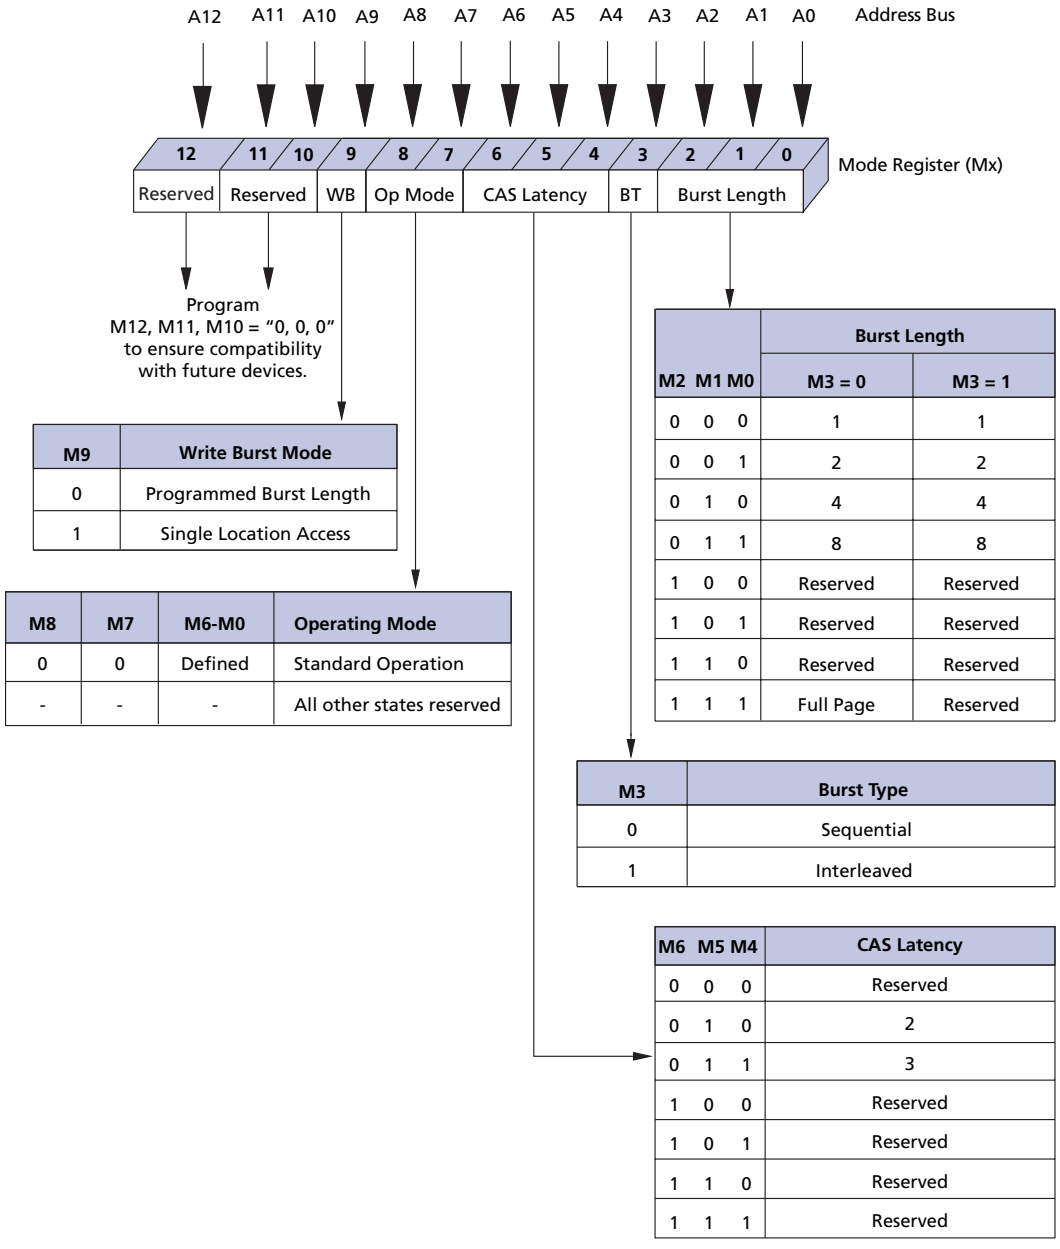
When a READ or WRITE command is issued, a block of columns equal to BL is effectively selected. All accesses for that burst take place within this block, meaning that the burst will wrap within the block if a boundary is reached, as shown in Figure 6 on page 10. The block is uniquely selected by A1–A9, A11 when BL = 2; A2–A9, A11 when BL = 4; and by A3–A9, A11 when BL is = 8. The remaining (least significant) address bit(s) is (are) used to select the starting location within the block. Full-page bursts wrap within the page if the boundary is reached, as shown in Table 6.

The ordering of accesses within a burst is determined by BL, the burst type and the starting column address, as shown in Table 6.

Burst Type

Accesses within a given burst may be programmed to be either sequential or interleaved; this is referred to as the burst type and is selected via bit M3.

Figure 4: Mode Register Definition Diagram



M9	Write Burst Mode
0	Programmed Burst Length
1	Single Location Access

M8	M7	M6-M0	Operating Mode
0	0	Defined	Standard Operation
-	-	-	All other states reserved

M2	M1	M0	Burst Length M3 = 0	Burst Length M3 = 1
0	0	0	1	1
0	0	1	2	2
0	1	0	4	4
0	1	1	8	8

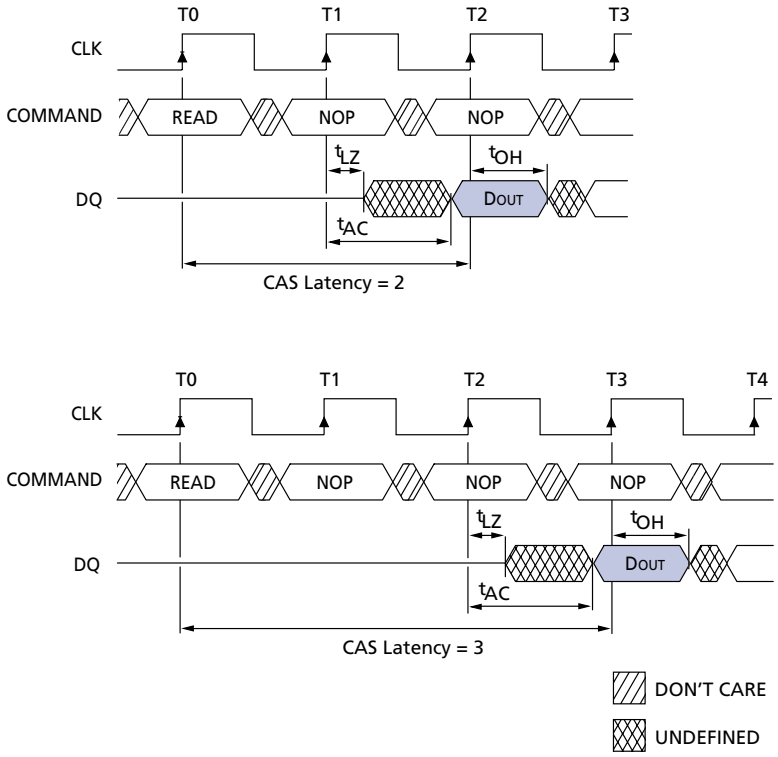
0	0	0	Reserved
0	1	0	2
0	1	1	3
1	0	0	Reserved
1	0	1	Reserved
1	1	0	Reserved
1	1	1	Reserved

Table 6: Burst Definition Table

Burst Length	Starting Column Address			Order of Accesses Within a Burst	
				Type = Sequential	Type = Interleaved
2			A0		
			0	0-1	0-1
			1	1-0	1-0
4		A1	A0		
		0	0	0-1-2-3	0-1-2-3
		0	1	1-2-3-0	1-0-3-2
		1	0	2-3-0-1	2-3-0-1
		1	1	3-0-1-2	3-2-1-0
8	A2	A1	A0		
	0	0	0	0-1-2-3-4-5-6-7	0-1-2-3-4-5-6-7
	0	0	1	1-2-3-4-5-6-7-0	1-0-3-2-5-4-7-6
	0	1	0	2-3-4-5-6-7-0-1	2-3-0-1-6-7-4-5
	0	1	1	3-4-5-6-7-0-1-2	3-2-1-0-7-6-5-4
	1	0	0	4-5-6-7-0-1-2-3	4-5-6-7-0-1-2-3
	1	0	1	5-6-7-0-1-2-3-4	5-4-7-6-1-0-3-2
	1	1	0	6-7-0-1-2-3-4-5	6-7-4-5-2-3-0-1
	1	1	1	7-0-1-2-3-4-5-6	7-6-5-4-3-2-1-0
Full Page (y)	n= A0–A9 (location 0-y)			Cn, Cn+1, Cn+2 Cn+3, Cn+4... ...Cn-1, Cn...	Not Supported

Notes:
1. For full-page accesses: y = 2,048.
2. For BL = 2, A1–A9, A11 select the block-of-two burst; A0 selects the starting column within the block.
3. For BL = 4, A2–A9, A11 select the block-of-four burst; A0–A1 select the starting column within the block.
4. For BL = 8, A3–A9, A11 select the block-of-eight burst; A0–A2 select the starting column within the block.
5. For a full-page burst, the full row is selected and A0–A9, A11 select the starting column.
6. Whenever a boundary of the block is reached within a given sequence above, the following access wraps within the block.
7. For BL = 1, A0–A9, A11 select the unique column to be accessed, and mode register bit M3 is ignored.

Figure 5: CAS Latency Diagram



CAS Latency

CL is the delay, in clock cycles, between the registration of a READ command and the availability of the first piece of output data. The latency can be set to two or three clocks.

If a READ command is registered at clock edge *n*, and the latency is m clocks, the data will be available by clock edge *n* + *m*. DQ will start driving as a result of the clock edge one cycle earlier (*n* + *m* - 1), and provided that the relevant access times are met, the data will be valid by clock edge *n* + *m*. For example, assuming that the clock cycle time is such that all relevant access times are met, if a read command is registered at T0 and the latency is programmed to two clocks, DQ will start driving after T1 and the data will be valid by T2, as shown in Figure 5. Table 6 on page 12, indicates the operating frequencies at which each CL setting can be used.

Reserved states should not be used as unknown operation or incompatibility with future versions may result.

Operating Mode

The normal operating mode is selected by setting M7 and M8 to zero; the other combinations of values for M7 and M8 are reserved for future use and/or test modes. The programmed BL applies to both read and write bursts.

Test modes and reserved states should not be used because unknown operation or incompatibility with future versions may result.

Write Burst Mode

When M9 = 0, the BL programmed via M0–M2 applies to both read and write bursts; when M9 = 1, the programmed BL applies to read bursts, but write accesses are single-location (nonburst) accesses.

Figure 6: CAS Latency Table
Registered mode adds one clock cycle to CL

Speed	Allowable Operating Clock Frequency (MHz)	
	CL = 2	CL = 3
-13E	≤ 133	≤ 143
-133	≤ 100	≤ 133

Commands

Table 7, provides a quick reference of available commands. This is followed by written description of each command. For a more detailed description of commands and operations, refer to the 256Mb SDRAM component data sheet.

Table 7: SDRAM Commands and DQMB Operation Truth Table
CKE is HIGH for all commands shown except SELF REFRESH

Name (Function)	CS#	RAS#	CAS#	WE#	DQMB	ADDR	DQ	Notes
COMMAND INHIBIT (NOP)	H	X	X	X	X	X	X	
NO OPERATION (NOP)	L	H	H	H	X	X	X	
ACTIVE (Select bank and activate row)	L	L	H	H	X	Bank/Row	X	1
READ (Select bank and column, and start READ burst)	L	H	L	H	L/H	Bank/Col	X	2
WRITE (Select bank and column, and start WRITE burst)	L	H	L	L	L/H	Bank/Col	Valid	2
BURST TERMINATE	L	H	H	L	X	X	Active	
PRECHARGE (Deactivate row in bank or banks)	L	L	H	L	X	Code	X	3
AUTO REFRESH or SELF REFRESH (Enter self refresh mode)	L	L	L	H	X	X	X	4, 5
LOAD MODE REGISTER	L	L	L	L	X	Op-code	X	6
Write Enable/Output Enable	–	–	–	–	L	–	Active	7
Write Inhibit/Output High-Z	–	–	–	–	H	–	High-Z	7

Notes:
1. A0–A12 provide row address; BA0–BA1 determine which device bank is made active.
2. A0–A9, A11 provide column address; A10 HIGH enables the auto-precharge feature (non-persistent), while A10 LOW disables the auto-precharge feature; BA0–BA1 determine which device bank is being read from or written to.
3. A10 LOW: BA0–BA1 determine which device bank is being precharged. A10 HIGH: all device banks are precharged and BA0, BA1 are "Don't Care."
4. This command is AUTO REFRESH if CKE is HIGH, SELF REFRESH if CKE is LOW.
5. Internal refresh counter controls row addressing; all inputs and I/Os are "Don't Care" except for CKE.
6. A0–A11 define the op-code written to the mode register and A12 should be driven LOW.
7. Activates or deactivates DQ during WRITEs (zero-clock delay) and READs (two-clock delay).

Electrical Specifications

Stresses greater than those listed may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

Figure 7: Absolute Maximum Ratings

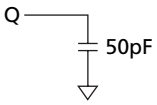
	CL = 2	tROH(2)	2	2	tCK	17, 33

Notes

1. All voltages referenced to V_{SS}.
2. This parameter is sampled. V_{DD}, $V_{DD}Q$ = +3.3V; f = 1 MHz; T_A = 25°C; pin under test biased at 1.4V.
3. I_{DD} is dependent on output loading and cycle rates. Specified values are obtained with minimum cycle time and the outputs open.
4. Enables on-chip refresh and address counters.
5. The minimum specifications are used only to indicate cycle time at which proper operation over the full temperature range is ensured (0°C ≤ T_A ≤ 55°C).
6. An initial pause of 100µs is required after power-up, followed by two AUTO REFRESH commands, before proper device operation is ensured. (V_{DD} and $V_{DD}Q$ must be powered up simultaneously. V_{SS} and $V_{SS}Q$ must be at same potential.) The two AUTO REFRESH command wake-ups should be repeated any time the ^{t}REF refresh requirement is exceeded.
7. AC characteristics assume ^{t}T = 1ns.
8. In addition to meeting the transition rate specification, the clock and CKE must transit between V_{IH} and V_{IL} (or between V_{IL} and V_{IH}) in a monotonic manner.
9. Outputs measured at 1.5V with equivalent load:



10. ^{t}HZ defines the time at which the output achieves the open circuit condition; it is not a reference to V_{OH} or V_{OL}. The last valid data element will meet ^{t}OH before going High-Z.
11. AC timing and I_{DD} tests have V_{IL} = 0V and V_{IH} = 3V, with timing referenced to 1.5V crossover point. If the input transition time is longer than 1ns, then the timing is referenced at V_{IL} (MAX) and V_{IH} (MIN) and no longer at the ISV crossover point.
12. Other input signals are allowed to transition no more than once every two clocks and are otherwise at valid V_{IH} or V_{IL} levels.
13. I_{DD} specifications are tested after the device is properly initialized.
14. Timing actually specified by ^{t}CKS; clock(s) specified as a reference only at minimum cycle rate.
15. Timing actually specified by ^{t}WR plus ^{t}RP; clock(s) specified as a reference only at minimum cycle rate.
16. Timing actually specified by ^{t}WR.
17. Required clocks are specified by JEDEC functionality and are not dependent on any timing parameter.
18. The I_{DD} current will increase or decrease proportionally according to the amount of frequency alteration for the test condition.
19. Address transitions average one transition every two clocks.
20. CLK must be toggled a minimum of two times during this period.
21. Based on ^{t}CK = 7.5ns for -133 and -13E.
22. V_{IH} overshoot: V_{IH} (MAX) = $V_{DD}Q$ + 2V for a pulse width ≤ 3ns, and the pulse width cannot be greater than one third of the cycle rate. V_{IL} undershoot: V_{IL} (MIN) = -2V for a pulse width ≤ 3ns.

23. The clock frequency must remain constant (stable clock is defined as a signal cycling within timing constraints specified for the clock pin) during access or precharge states (READ, WRITE, including ^{t}WR, and PRECHARGE commands). CKE may be used to reduce the data rate.
24. Auto precharge mode only. The precharge timing budget (^{t}RP) begins at 7ns for -13E; and 7.5ns for -133 after the first clock delay, after the last WRITE is executed. May not exceed limit set for precharge mode.
25. Precharge mode only.
26. JEDEC specifies three clocks.
27. ^{t}AC for -133/-13E at CL = 3 with no load is 4.6ns and is guaranteed by design.
28. Parameter guaranteed by design.
29. For -13E, CL = 2 and ^{t}CK = 7.5ns; and for -133, CL = 3 and ^{t}CK = 7.5ns
30. CKE is HIGH during refresh command period ^{t}RFC (MIN) else CKE is LOW. The IDD6 limit is actually a nominal value and does not result in a fail value.
31. Refer to device data sheet for timing waveforms.
32. The value of ^{t}RAS used in -13E speed grade modules is calculated from ^{t}RC - ^{t}RP = 45ns.
33. This AC timing function will show an extra clock cycle when input register is in registered mode.
34. Leakage number reflects the worst case leakage possible through the module pin, not what each memory device contributes.

PLL and Register Specifications

Table 13: Register Timing Requirements and Switching Characteristics

Register	Symbol	Parameter	Condition	0°C ≤ T_A ≤ 55°C VDD = +3.3V ±0.3V		Units
				Min	Max	
SSTL bit pattern by JESD82-2	f_{clock}	Clock frequency		150	240	MHz
	t_{pd1}	Propagation delay, Single rank (CK to output)	50pF to GND and 50Ω to VTT	1.4	3.5	ns
	t_{pd2}	Propagation delay, Dual rank (CK to output)	30pF to GND and 50Ω to VTT	0.7	2.4	ns
	t_w	Pulse duration	CK, HIGH or LOW	3.3	-	ns
	t_{su}	Setup time	Data before CK HIGH	.75	-	ns
	t_h	Hold time	Data after CK HIGH	.75	-	ns

Table 14: PLL Clock Driver Timing Requirements And Switching Characteristics

Parameter	Symbol	0°C ≤ T_A ≤ 55°C VDD = +3.3V ±0.3V		Units	Notes
		Min	Max		
Operating clock frequency	^{f}CK	50	140	MHz	
Input duty cycle	^{t}DC	44	55	%	
Cycle to cycle jitter	$^{t}JIT_{cc}$	-75	75	ps	
Static phase offset	$^{t}\varnothing$	-150	150	ps	
SSC induced skew	^{t}SSC	–	150	ps	1, 2
Output to output skew	$^{t}SK_{O}$	–	150	ps	

Notes: 1. SSC = Spread spectrum clock. The use of SSC synthesizers on the system motherboard will reduce EMI.
2. Skew is defined as the total clock skew between any two outputs and is therefore specified as a maximum only.

Serial Presence-Detect

SPD Clock and Data Conventions

Data states on the SDA line can change only during SCL LOW. SDA state changes during SCL HIGH are reserved for indicating start and stop conditions (as shown in Figure 8, and Figure 9 on page 20).

SPD Start Condition

All commands are preceded by the start condition, which is a HIGH-to-LOW transition of SDA when SCL is HIGH. The SPD device continuously monitors the SDA and SCL lines for the start condition and will not respond to any command until this condition has been met.

SPD Stop Condition

All communications are terminated by a stop condition, which is a LOW-to-HIGH transition of SDA when SCL is HIGH. The stop condition is also used to place the SPD device into standby power mode.

SPD Acknowledge

Acknowledge is a software convention used to indicate successful data transfers. The transmitting device, either master or slave, will release the bus after transmitting eight bits. During the ninth clock cycle, the receiver will pull the SDA line LOW to acknowledge that it received the 8 bits of data (as shown in Figure 10 on page 20).

The SPD device will always respond with an acknowledge after recognition of a start condition and its slave address. If both the device and a WRITE operation have been selected, the SPD device will respond with an acknowledge after the receipt of each subsequent 8-bit word. In the read mode the SPD device will transmit eight bits of data, release the SDA line and monitor the line for an acknowledge. If an acknowledge is detected and no stop condition is generated by the master, the slave will continue to transmit data. If an acknowledge is not detected, the slave will terminate further data transmissions and await the stop condition to return to standby power mode.

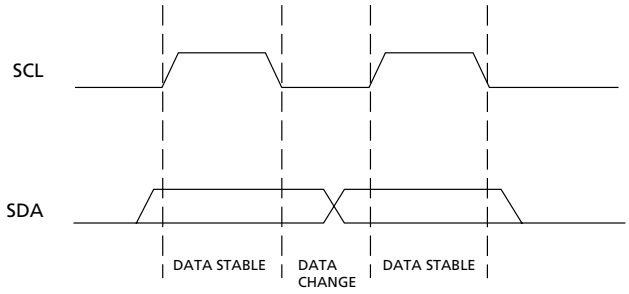

Figure 9: Definition of Start and Stop

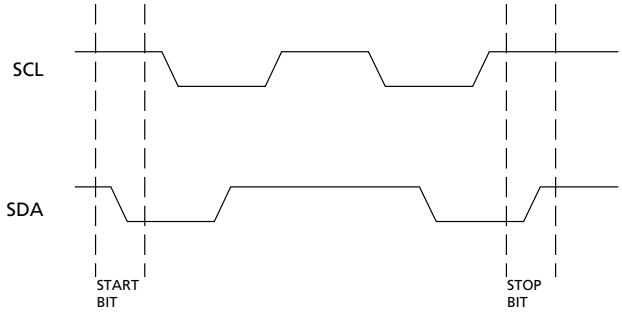

Figure 10: Acknowledge Response From Receiver

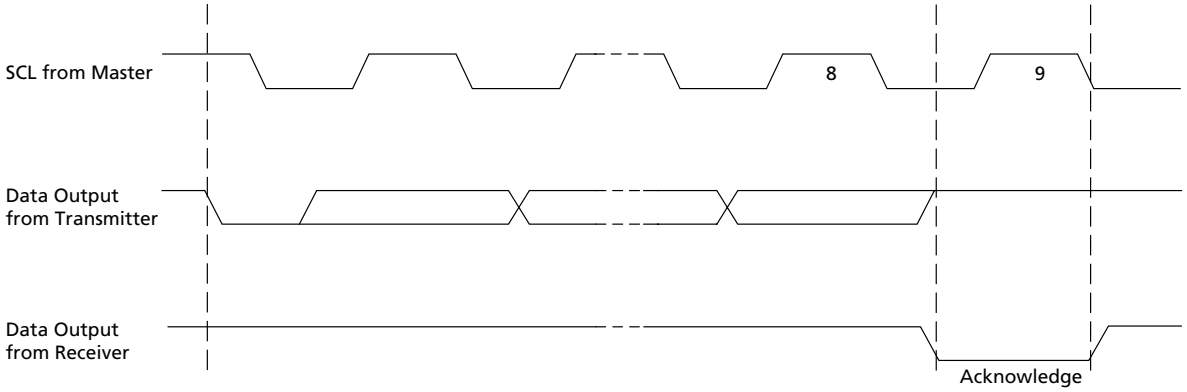

Table 15: EEPROM Device Select Code

The most significant bit (b7) is sent first

Select Code	Device Type Identifier				Chip Enable			RW
	b7	b6	b5	b4	b3	b2	b1	b0
Memory area select code (two arrays)	1	0	1	0	SA2	SA1	SA0	RW
Protection register select code	0	1	1	0	SA2	SA1	SA0	RW

Table 16: EEPROM Operating Modes

Mode	RW Bit	WC	Bytes	Initial Sequence
Current address read	1	VIH or VIL	1	Start, Device select, RW = 1
Random address read	0	VIH or VIL	1	Start, Device select, RW= 0, Address
	1	VIH or VIL		Restart, Device select, RW= 1
Sequential read	1	VIH or VIL	≥ 1	Similar to current or random address read
Byte write	0	VIL	1	Start, Device select, RW = 0
Page write	0	VIL	≤ 16	Start, Device select, RW = 0

Figure 11: SPD EEPROM Timing Diagram

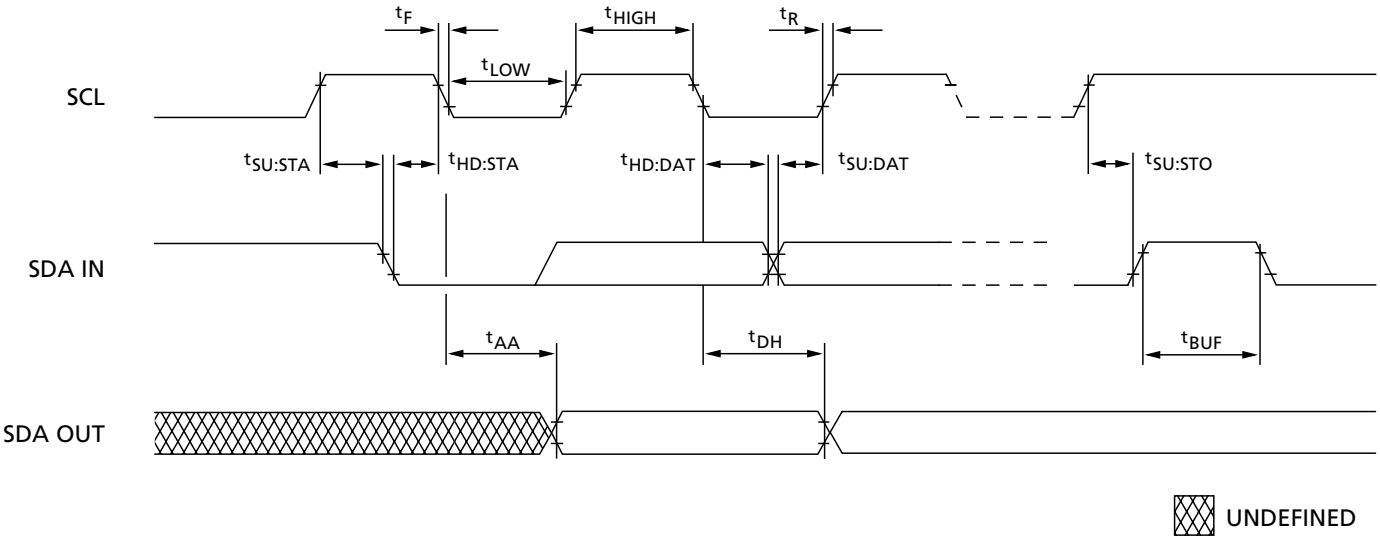

Table 17: Serial Presence-Detect EEPROM DC Operating Conditions
All voltages referenced to V_{SS}; V_{DDSPD} = +3.3V ±0.3V

Parameter/Condition	Symbol	Min	Max	Units
Supply voltage	V_{DD}	3	3.6	V
Input high voltage: Logic 1; All inputs	V_{IH}	V_{DD} x 0.7	V_{DD} + 0.5	V
Input low voltage: Logic 0; All inputs	V_{IL}	-1	V_{DD} x 0.3	V
Output low voltage: I_{OUT} = 3mA	V_{OL}	–	0.4	V
Input leakage current: V_{IN} = GND to V_{DD}	I_{LI}	-10	10	µA
Output leakage current: V_{OUT} = GND to V_{DD}	I_{LO}	-10	10	µA
Standby current: SCL = SDA = V_{DD} - 0.3V; All other inputs = V_{SS} or V_{DD}	I_{CCS}	–	30	µA
Power supply current	I_{CC} Write	–	3	mA
	I_{CC} Read	–	1	mA

Table 18: Serial Presence-Detect EEPROM AC Operating Conditions

All voltages referenced to V_{SS}; V_{DDSPD} = +3.3V ±0.3V

Parameter/Condition	Symbol	Min	Max	Units	NOTES
SCL LOW to SDA data-out valid	^{t}AA	0.2	0.9	µs	1
Time the bus must be free before a new transition can start	^{t}BUF	1.3		µs	
Data-out hold time	^{t}DH	200		ns	
SDA and SCL fall time	^{t}F		300	ns	2
Data-in hold time	$^{t}HD:DAT$	0		µs	
Start condition hold time	$^{t}HD:STA$	0.6		µs	
Clock HIGH period	$^{t}HIGH$	0.6		µs	
Noise suppression time constant at SCL, SDA inputs	^{t}I		50	ns	
Clock LOW period	^{t}LOW	1.3		µs	
SDA and SCL rise time	^{t}R		0.3	µs	2
SCL clock frequency	^{f}SCL		400	KHz	
Data-in setup time	$^{t}SU:DAT$	100		ns	
Start condition setup time	$^{t}SU:STA$	0.6		µs	3
Stop condition setup time	$^{t}SU:STO$	0.6		µs	
WRITE cycle time	^{t}WRC		10	ms	4

Notes:
1. To avoid spurious start and stop conditions, a minimum delay is placed between SCL = 1 and the falling or rising edge of SDA.
2. This parameter is sampled.
3. For a restart condition, or following a WRITE cycle.
4. The SPD EEPROM WRITE cycle time (^{t}WRC) is the time from a valid stop condition of a write sequence to the end of the EEPROM internal erase/program cycle. During the WRITE cycle, the EEPROM bus interface circuit is disabled, SDA remains HIGH due to pull-up resistor, and the EEPROM does not respond to its slave address.
