

INERTIAL SENSOR: 3Axis - 2g/6g DIGITAL OUTPUT LINEAR ACCELEROMETER

PRODUCT PREVIEW

- 2.7V TO 3.6V SINGLE SUPPLY OPERATION
- I2C/SPI DIGITAL OUTPUT INTERFACES
- MOTION ACTIVATED INTERRUPT SOURCE FACTORY TRIMMED DEVICE SENSITIVITY AND OFFSET
- EMBEDDED SELF TEST
- HIGH SHOCK SURVIVABILITY

DESCRIPTION

The LIS3L02DS is a tri-axis digital output linear accelerometer that includes a sensing element and an IC interface able to take the information from the sensing element and to provide the measured acceleration signals to the external world through an I2C/SPI serial interface.

The sensing element, capable to detect the acceleration, is manufactured using a dedicated process called THELMA (Thick Epi-Poly Layer for Microactuators and Accelerometers) developed by ST to produce inertial sensors and actuators in silicon.

The IC interface instead is manufactured using a CMOS process that allows high level of integration to design a dedicated circuit which is factory trimmed to better match the sensing element characteristics.

The LIS3L02DS has a user selectable full scale of 2g, 6g and it is capable of measuring accelerations

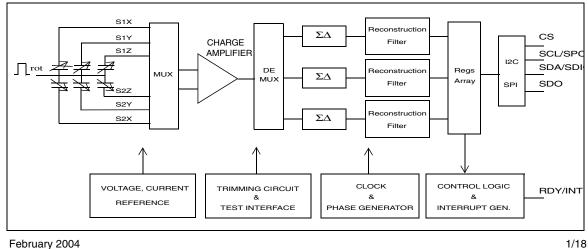

over a maximum bandwidth of 2.0 KHz for the X, Y axis and Z axis. The device bandwidth may be programmed accordingly to the application requirements. A self-test capability allows the user to check the functioning of the system.

The device may be configured to generate an inertial wake-up/interrupt signal when a programmable acceleration threshold is exceeded along one of the three axis.

The LIS3L02DS is available in plastic SMD package and it is specified over a temperature range extending from -40°C to +85°C.

The LIS3L02DS belongs to a family of products suitable for a variety of applications:

- Antitheft systems and Inertial navigation
- Virtual reality input devices
- Vibration Monitoring, recording and compensation
- Robotics and Appliance control

February 2004

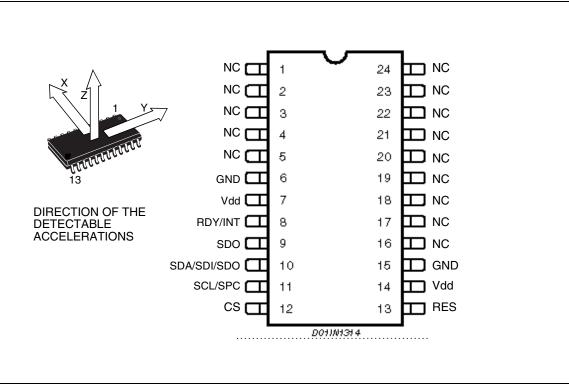

BLOCK DIAGRAM

This is preliminary information on a new product now in development. Details are subject to change without notice.

PIN DESCRIPTION

N°	Pin	Function
1 to 5	NC	Internally not connected
6	GND	OV supply
7	Vdd	Power supply
8	RDY/INT	Data ready/inertial wake-up interrupt
9	SDO	SPI Serial Data Output
10	SDA/ SDI/ SDO	I2C Serial Data (SDA) SPI Serial Data Input (SDI) 3-wire Interface Serial Data Output (SDO)
11	SCL/SPC	I2C Serial Clock (SCL) SPI Serial Port Slock (SPC)
12	CS	SPI enable I2C/SPI mode selection (1: I2C mode; 0: SPI enabled)
13	RES	Reserved. Either leave unconnected or connect to Vdd
14	Vdd	Power supply
15	GND	0V supply
16 to 24	NC	Internally not connected

PIN CONNECTION (Top view)

ELECTRICAL CHARACTERISTCS (Temperature range -40°C to +85°C)

All the parameters are specified @ Vdd=3.3V and T=25°C unless otherwise noted

Symbol	Parameter	Test Condition	Min.	Typ. ¹	Max.	Unit
Vdd	Supply voltage		2.7		3.6	V
ldd	Supply current	T = 25°C		1	1.5	mA
lddPdn	Current consumption in power-down mode	T = 25°C			10	μA
BW	Digital Filter Cut-Off frequency (-3dB)			70	1150	Hz
FS	Measurement range ²	FS bit set to 0		±2.0		g
		FS bit set to 1		±6.0		g
FSAcc	Full-scale accuracy	T = 25°C Full-scale = 2g	FS-10%	FS	FS+10%	g
		T = 25°C Full-scale = 6g	FS-15%	FS	FS+15%	g
So	Device Resolution	T = 25°C Full-scale = 2g BW=56Hz		1		mg
0g-Offset	Zero g level	T = 25°C Full-scale = 2g	-50		50	mg
NL	Non Linearity	Best fit straight line X, Y axis Full-scale = 2g BW=56Hz		±1		% FS
		Best fit straight line Z axis Full-scale = 2g BW=56Hz		±3		% FS
DR1	Output data rate	Dec factor = 128		280		Hz
DR2	Output data rate	Dec factor = 64		560		Hz
DR3	Output data rate	Dec factor = 32		1120		Hz
DR4	Output data rate	Dec factor = 8		4480		Hz
Ton	Turn-on time			50		ms

Notes

¹ Typical specifications are not guaranteed ² Guaranteed by wafer level test and measurement of initial offset and sensitivity

ABSOLUTE MAXIMUM RATING

Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device under these conditions is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

Symbol	Ratings	Maximum Value	Unit
Vdd	Supply voltage	-0.3 to 6	V
Vin	Input voltage on any control pin (CS, SCL/SPC, SDA/SDI/SDO, SDO, RDY/INT)	Vss -0.3 to Vdd +0.3	V
A _{POW}	Acceleration (Any axis, Powered, Vdd=3.3V)	3000g for 0.5 ms	
AUNP	Acceleration (Any axis, Unpowered)	3000g for 0.5 ms	
T _{OP}	Operating Temperature Range	-40 to +85	°C
T _{STG}	Storage Temperature Range	-40 to +105	°C

1 FUNCTIONALITY

1.1 Sensing element

The THELMA process is utilized to create a surface micro-machined accelerometer. The technology allows to carry out suspended silicon structures which are attached to the substrate in a few points called anchors and free to move on a plane parallel to the substrate itself. To be compatible with the traditional packaging techniques a cap is placed on top of the sensing element to avoid blocking the moving parts during the molding phase.

The equivalent circuit for the sensing element is shown in the below figure; when a linear acceleration is applied, the proof mass displaces from its nominal position, causing an imbalance in the capacitive halfbridge. This imbalance is measured using charge integration in response to a voltage pulse applied to the sense capacitor.

The nominal value of the capacitors, at steady state, is few pF and when an acceleration is applied the maximum variation of the capacitive load is few tenth of pF.

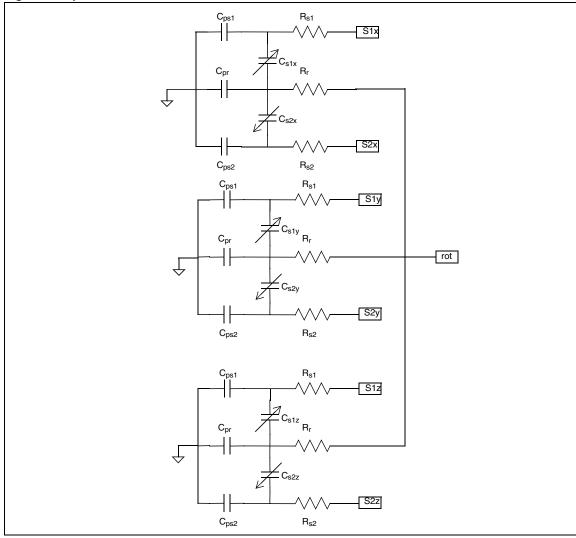

Figure 1. Equivalent electrical circuit

1.2 IC Interface

The complete measurement chain is composed by a low-noise capacitive amplifier which converts into an analog voltage the capacitive unbalancing of the MEMS sensor and by three $\Sigma\Delta$ analog-to-digital converters, one for each axis, that translates the produced signal into a digital bitstream.

The $\Sigma\Delta$ converters are tigthly coupled with dedicated reconstruction filters which removes the high frequency components of the quantization noise and provides low rate and high resolution digital words.

The charge amplifier and the $\Sigma\Delta$ converters are operated respectively at 107.5 KHz and 35.8 KHz.

The data rate at the output of the reconstruction depends on the user selected Decimation Factor (DF) and span from 280 Hz to 4.48 KHz.

The acceleration data may be accessed through an I2C/SPI interface thus making the device particularly suitable for direct interfacing with a microcontroller.

The LIS3L02DS features a Data-Ready signal (DRY) which indicated when a new set of measured acceleration data is available thus simplifying data synchronization in digital system employing the device itself.

The LIS3L02DS may also be configured to generate an inertial wake-up/interrupt signal when a programmable acceleration threshold is exceeded along one of the three axis.

1.3 Factory calibration

The IC interface is factory calibrated to provide to the final user a device ready to operate. The parameters which are trimmed are: gain, offset, common mode and internal clock frequency.

The trimming values are stored inside the device by a non volatile structure. Any time the device is turned on, the trimming parameters are downloaded into the registers to be employed during the normal operation thus allowing the final user to employ the device without any need for further calibration

2 DIGITAL INTERFACES

The registes embedded inside the LIS3L02DS may be accessed through both the 2C and SPI serial interfaces. The latter may be SW configured to operate either in SPI mode or in 3-wire interface mode. The serial interfaces are mapped onto the same pads. To select/exploit the I2C interface, CS line must be tied high (i.e connected to Vdd).

PIN Name	PIN Description
CS	SPI enable I2C/SPI mode selection (1: I2C mode; 0: SPI enabled)
SCL/SPC	I2C Serial Clock (SCL) SPI Serial Port Slock (SPC)
SDA/SDI/SDO	I2C Serial Data (SDA) SPI Serial Data Input (SDI) 3-wire Interface Serial Data Output (SDO)
SDO	SPI Serial Data Output (SDO)

Table 1. Serial Interface Pin Description

2.1 I2C Serial Interface

The LIS3L02DS I2C is a bus slave. The I2C is employed to write the data into the registers whose content can also be read back.

The relevant I²C terminology is given in the table below

 Table 2. Serial Interface Pin Description

Term	Description
Transmitter	The device which sends data to the bus
Receiver	The device which receives data from the bus
Master	The device which initiates a transfer, generates clock signals and terminates a transfer
Slave	The device addressed by the master

There are two signals associated with the I^2C bus: the Serial Clock Line (SCL) and the Serial DAta line (SDA). The latter is a bidirectional line used for sending and receiving the data to/form the interface. Both the lines are connected to Vdd through a pull-up resistor embedded inside the LIS3L02DS. When the bus is free both the lines are high.

2.1.1 I²C Operation

The transaction on the bus is started through a START signal. A START condition is defined as a HIGH to LOW transition on the data line while the SCL line is held HIGH. After this has been transmitted by the Master, the bus is considered busy. The next byte of data transmitted after the start condition contains the address of the slave in the first 7 bits and the eighth bit tells whether the Master is receiving data from the slave or transmitting data to the slave. When an address is sent, each device in the system compares the first seven bits after a start condition with it's address. If they match, the device considers itself addressed by the Master. The address can be made up of a programmable part and a fixed part, thus allowing more than one device of the same type to be connected to the I^2C bus.

The Slave ADdress (SAD) associated to the LIS3L02DS is 0011101.

Data transfer with acknowledge is mandatory. The transmitter must release the SDA line during the ac-

knowledge pulse. The receiver must then pull the data line LOW so that it remains stable low during the HIGH period of the acknowledge clock pulse. A receiver which has been addressed is obliged to generate an acknowledge after each byte of data has been received.

The I²C embedded inside the Gengine ASIC behaves like a slave device and the following protocol must be adhered to. After the start condition (ST) a salve address is sent, once a slave acknowledge has been returned, a 8-bit sub-address will be transmitted: the 7 LSB represent the actual register address while the MSB enables address autoincrement. If the MSB of the SUB field is 1, the SUB (register address) will be automatically incremented to allow multiple data read/write.

If the LSB of the slave address was '1' (read), a repeated START condition will have to be issued after the two sub-address bytes; if the LSB is '0' (write) the Master will transmit to the slave with direction unchanged.

Transfer when Master is writing one byte to slave

Master	ST	SAD + W		SUB		DATA		SP
Slave			SAK		SAK		SAK	

Transfer when Master is writing multiple bytes to slave:

Master	ST	SAD + W		SUB		DATA		DATA		SP
Slave			SAK		SAK		SAK		SAK	

Transfer when Master is receiving (reading) one byte of data from slave:

Ма	ster	ST	SAD + W		SUB		SR	SAD + R			NMAK	SP
Sla	ive			SAK		SAK			SAK	DATA		

Transfer when Master is receiving (reading) multiple bytes of data from slave

Master	ST	SAD + W		SUB		SR	SAD + R			MAK
Slave			SAK		SAK			SAK	DATA	

Master	SR		MAK		NMAK	SP
Slave		DATA		DATA		

Data are transmitted in byte format. Each data transfer contains 8 bits. The number of bytes transferred per transfer is unlimited. Data is transferred with the Most Significant Bit (MSB) first. If a receiver can't receive another complete byte of data until it has performed some other function, it can hold the clock line, SCL LOW to force the transmitter into a wait state. Data transfer only continues when the receiver is ready for another byte and releases the data line. If a slave receiver doesn't acknowledge the slave address (i.e. it is not able to receive because it is performing some real time function) the data line must be left HIGH by the slave. The Master can then abort the transfer. A LOW to HIGH transition on the SDA line while the SCL line is HIGH is defined as a STOP condition. Each data transfer must be terminated by the generation of a STOP condition.

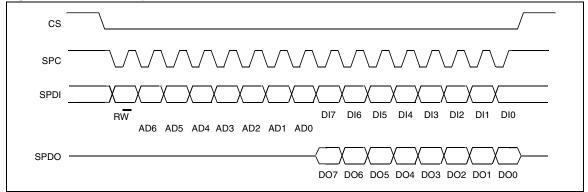

In order to read multiple bytes, it is necessary to assert the most significant bit of the sub-address field. In other words, SUB(7) must be equal to 1 while SUB(6-0) represents the address of first register to read.

2.2 SPI Bus Interface

The Gengine SPI is a bus slave. The SPI allows to write and read the registers of the device. The Serial Interface interacts with the outside world with 4 wires: CS, SPC, SPDI and SPDO.

2.2.1 Read & Write registers

Figure 2. Read & write protocol

CS is the Serial Port Enable and it is controlled by the SPI master. It goes low at the start of the transmission and goes back high at the end. SPC is the Serial Port Clock and it is controlled by the SPI master. It is stopped high when CS is high (no transmission). SPDI and SPDO are respectively the Serial Port Data Input and Output. Those lines are driven at the falling edge of SPC and should be captured at the rising edge of SPC.

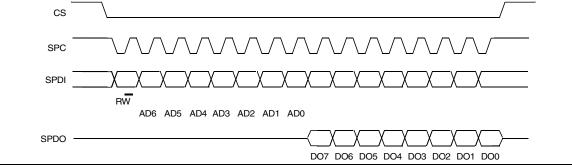

Both the Read Register and Write Register commands are completed in 16 clocks pulses. Bit duration is the time between two falling edges of SPC. The first bit (bit 0) starts at the first falling edge of SPC after the falling edge of CS while the last bit (bit 15) starts at the last falling edge of SPC just before the rising edge of CS.

- bit 0: RW bit. When 0, the data DI(7:0) is written into the device. When 1, the data DO(7:0) from the device is read. In latter case, the chip will drive SPDO at the start of bit 8.
- bit 1-7: address AD(6:0). This is the address field of the indexed register.
- bit 8-15: data DI(7:0) (write mode). This is the data that will be written into the device (MSb first).
- bit 8-15: data DO(7:0) (read mode). This is the data that will be read from the device (MSb first).

2.2.2 SPI Read

Figure 3. SPI Read protocol

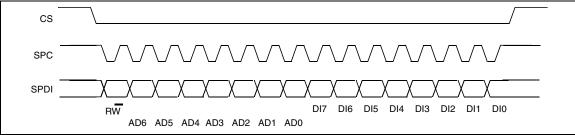

The SPI Read command consists is performed with 16 clocks pulses:

- bit 0: READ bit. The value is 1.
- bit 1-7: address AD(6:0). This is the address field of the indexed register.
- bit 8-15: data DO(7:0) (read mode). This is the data that will be read from the device (MSb first).

2.2.3 SPI Write

Figure 4. SPI Write protocol

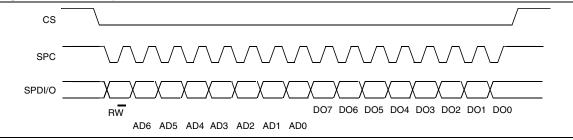

The SPI Write command consists is performed with 16 clocks pulses.

- bit 0: WRITE bit. The value is 0.
- bit 1-7: address AD(3:0). This is the address field of the indexed register.
- bit 8-15: data DI(7:0) (write mode). This is the data that will be written inside the device (MSb first).

2.2.4 SPI Read in 3-wires mode

3-wires mode is entered by setting to 1 bit SIM (SPI Serial Interface Mode selection) in A_IF_CTRL2.

Figure 5. SPI Read protocol in 3-wires model

The SPI Read command consists is performed with 16 clocks pulses:

- bit 0: READ bit. The value is 1.
- bit 1-7: address AD(6:0). This is the address field of the indexed register.
- bit 8-15: data DO(7:0) (read mode). This is the data that will be read from the device (MSb first).

ZYXDA	X, Y and Z	X, Y and Z axis new Data Available							
ZDA	Z axis new	Z axis new Data Available							
YDA	Y axis nev	Y axis new Data Available							
XDA	X axis nev	v Data Av	ailable						

4.13 OUTX_L (28h)

|--|

XD7, XD0

X axis acceleration data LSb

4.14 OUTX_H (29h)

When reading the register in "12 bit right justified" mode the most significant bits (7:4) are replaced with bit 3 (i.e. XD15-XD12=XD11, XD11, XD11, XD11).
