Architecture Overview

The QuickRAM™ family of Embedded Standard Products (ESP) offer FPGA logic in combination with Dual-Port SRAM modules. The QuickRAM family of ESPs have up to 90,000 usable PLD gates. QuickRAM ESPs are fabricated on a 0.35 µm four-layer metal process using QuickLogic's patented ViaLink™ technology to provide a unique combination of high performance, high density, low cost, and extreme ease-of-use.

The QuickRAM family contains a range of 160 to 1,584 logic cells and 8 to 22 dual port RAM Modules (see **Figure 1**). Each RAM Module has 1,152 RAM bits, for a total ranging from 9,216 to 25,344 bits (see **Table 1**). RAM Modules are dual port (one read port, one write port) and can be configured into one of four modes: 64 (deep) x18 (wide), 128x9, 256x4, or 512x2 (see **Figure 2**). With a maximum of 308 I/Os, the QuickRAM family of ESPs are available in many device/package combinations (see **Table 2**).

Designers can cascade multiple RAM Modules to increase the depth or width allowed in single modules by connecting corresponding address lines together and dividing the words between modules (see **Figure 3**). This approach allows up to 512-deep configurations as large as 16 bits wide in the smallest QuickRAM device and 44 bits wide in the largest device.

Software support for the complete QuickRAM family is available through two basic packages. The turnkey QuickWorks™ package provides the most complete ESP software solution from design entry to logic synthesis, to place and route, to simulation. The QuickTools™ packages provides a solution for designers who use Cadence, Exemplar, Mentor, Synopsys, Synplicity, Viewlogic, Aldec, or other third-party tools for design entry, synthesis, or simulation.

The QuickLogic variable grain logic cell features up to 16 simultaneous inputs and 5 outputs within a cell that can be fragmented into 5 independent cells. Each cell has a fan-in of 29 including register and control lines (see **Figure 4**).

Power-Up Sequencing

Figure 8: Power-Up Requirements

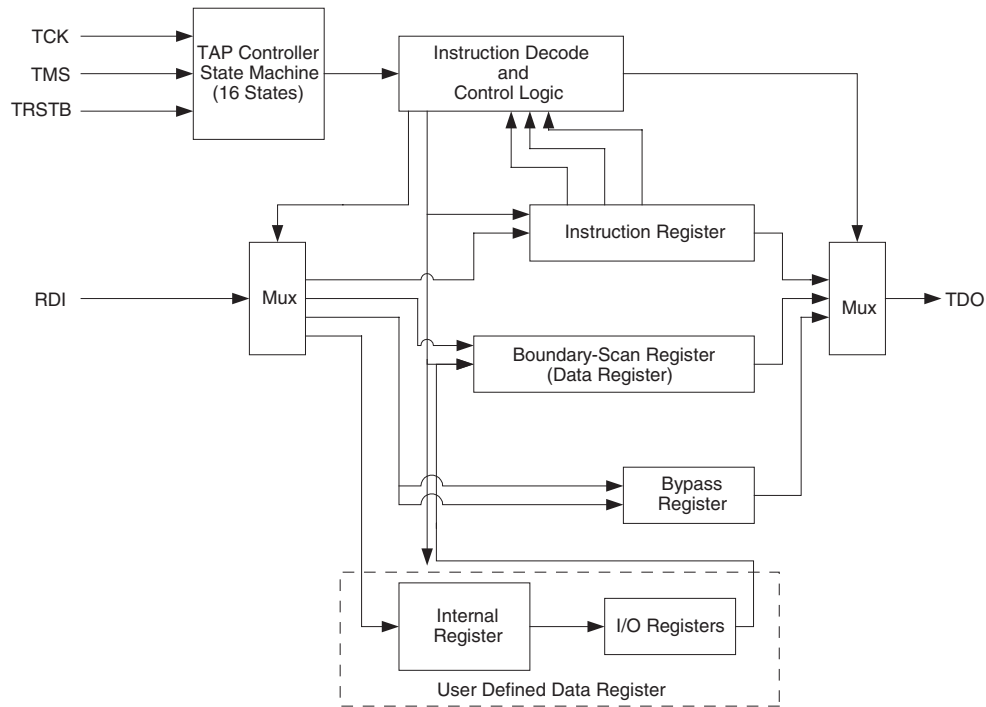

When powering up a device, the V_{CC}/V_{CCIO} rails must take 400 μs or longer to reach the maximum value (refer to **Figure 7**).

NOTE: Ramping V_{CC}/V_{CCIO} to the maximum voltage faster than 400 μs can cause the device to behave improperly.

For users with a limited power budget, keep $(V_{CCIO} - V_{CC})_{MAX} \leq 500 \text{ mV}$ when ramping up the power supply.

JTAG

Figure 9: JTAG Block Diagram

Microprocessors and Application Specific Integrated Circuits (ASICs) pose many design challenges, not the least of which concerns the accessibility of test points. The Joint Test Access Group (JTAG) formed in response to this challenge, resulting in IEEE standard 1149.1, the Standard Test Access Port and Boundary Scan Architecture.

The JTAG boundary scan test methodology allows complete observation and control of the boundary pins of a JTAG-compatible device through JTAG software. A Test Access Port (TAP) controller works in concert with the Instruction Register (IR); these allow users to run three required tests, along with several user-defined tests.

JTAG tests allow users to reduce system debug time, reuse test platforms and tools, and reuse subsystem tests for fuller verification of higher level system elements.

The 1149.1 standard requires the following three tests:

- **Exttest Instruction.** The Exttest Instruction performs a Printed Circuit Board (PCB) interconnect test. This test places a device into an external boundary test mode, selecting the boundary scan register to be connected between the TAP Test Data In (TDI) and Test Data Out (TDO) pins. Boundary scan cells are preloaded with test patterns (via the Sample/Preload Instruction), and input boundary cells capture the input data for analysis.
- **Sample/Preload Instruction.** The Sample/Preload Instruction allows a device to remain in its functional mode, while selecting the boundary scan register to be connected between the TDI and TDO pins. For this test, the boundary scan register can be accessed via a data scan operation, allowing users to sample the functional data entering and leaving the device.

- **Bypass Instruction.** The Bypass Instruction allows data to skip a device boundary scan entirely, so the data passes through the bypass register. The Bypass instruction allows users to test a device without passing through other devices. The bypass register is connected between the TDI and TDO pins, allowing serial data to be transferred through a device without affecting the operation of the device.
