

# DAC-7134B, DAC-7134U

## 14-Bit Microprocessor-compatible Multiplying D/A Converters

T-51-09-90

**FEATURES**

- 14-Bit linearity (0.003% FSR)
- Microprocessor-compatible with doubled-buffered inputs
- 3 Microsecond maximum output current settling time (0.9μS typical)
- Low power dissipation
- Full four-quadrant multiplication
- Gain Tempco of +/-8ppm/degree C maximum
- PROM-controlled correction circuits

**GENERAL DESCRIPTION**

The DAC-7134 achieves true 14-bit linearity by combining a four-quadrant, multiplying DAC with on-chip, PROM-controlled correction circuits. The DAC uses thin-film resistors and CMOS circuitry for stability while the PROM-controlled correction circuit eliminates errors introduced by the thermal stresses of packaging.

There are two versions of the DAC-7134, both represented by the block diagram, Figure 1. The DAC-7134U is programmed for unipolar operation while the DAC-7134B is programmed for bipolar applications. Microprocessor bus interfacing is easy using standard memory write cycle timing and control signals. Two input buffer registers are separately loaded with the 8 least significant bits (LS register) and the 6 most significant bits (MS register). Their contents are then transferred to the 14-bit DAC register, which controls the output switches. The DAC register can also be loaded directly from the data inputs.

There are two reference voltage inputs feeding the resistor ladder network. The  $V_{REF}$  input to the most significant bit of the DAC is separated from the reference input to the remainder of the ladder.

For unipolar use, the two reference inputs are tied together. For bipolar applications, the polarity of the MSB reference is reversed through an external operational amplifier. This flexibility gives the DAC a true 2's complement input transfer function. The DAC-7134 contains two resistors used along with the external op-amp to invert the reference. The PROM is coded to correct for errors in these resistors as well as the inversion of the MSB.

Operating Temperature Range	0	-	+70	°C
Storage Temperature Range	-65	-	+150	°C
Package	28-pin Cerdip only			

The timing diagram represented in Figure 2 shows the relationships between the various bus interface signals. These AC characteristics are listed in Table 1.

## DETAILED DESCRIPTION

The DAC-7134 consists of a 14-bit primary DAC, two PROM-controlled correction DAC's, input buffer registers, and microprocessor interface logic (refer back to Figure 1). The 14-bit primary DAC is an R-2R thin film resistor ladder with N-channel MOS SPDT current steering switches. Precise balancing of the switch resistances, and all other resistances in the ladder, results in excellent temperature stability.

True 14-bit linearity is achieved by programming a floating polysilicon gate PROM array which controls two correction DAC circuits. A 6-bit gain correction DAC (G-DAC) diverts up to 2% of the feedback resistor's current to analog ground and reduces the gain error to less than 1 LSB, or 0.006%.

The 5 most significant outputs of the DAC register address a 31-word PROM array that controls a 12-bit linearity correction DAC (C-DAC). For every combination of the primary DAC's most significant bits, a different C-DAC code is selected. This corrects summation errors (caused when more than one bit is turned on simultaneously) and voltage non-linearity in the feedback resistor.

**PIN DESCRIPTIONS**

The input and output pins for both the analog and digital signals used by the DAC-7134 are listed in Table 2 and shown in Figure 3.

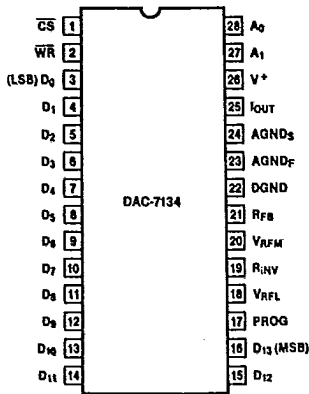

Figure 3. DAC-7134 Pin Configuration

**ANALOG SECTION**

The DAC-7134 provides both unipolar and bipolar operation. The bipolar application circuit (Figure 4) requires one additional operational amplifier, but no external resistors. Two on-chip resistors (R<sub>INV1</sub>, R<sub>INV2</sub>), together with the op-amp, form a voltage inverter which drives the MSB reference terminal (V<sub>REFM</sub>) to -V<sub>REF</sub>.

V<sub>REF</sub> is the voltage applied at the less significant bits' reference terminal, V<sub>REFL</sub>. This reverses the weight of the MSB, and gives the DAC a 2's complement transfer function. The op-amp and reference connection to V<sub>REFM</sub> and V<sub>REFL</sub> can be reversed, without affecting linearity, but a small gain error will be introduced. For unipolar operation the V<sub>REFM</sub> and V<sub>REFL</sub> terminals are both tied to V<sub>REF</sub>, and the R<sub>INV</sub> pin is left unconnected.

Figure 4. Bipolar Operation, with Inverted V<sub>REF</sub> to MSB

2

**DAC-7134B, DAC-7134U**

Since the PROM correction codes required are different for bipolar and unipolar operation, the DAC-7134 is available in two different versions; the DAC-7134U, which is corrected for unipolar operation, and the DAC-7134B, which is programmed for bipolar application. The feedback resistance is also different in the two versions, and is switched under PROM control from "R" in the unipolar device to "2R" in the bipolar part. These feedback resistors have a dummy (always ON) switch in series to compensate for the effect of the ladder switches. This greatly improves the gain temperature coefficient and the power supply rejection of the device.

**DIGITAL SECTION**

Two levels of input buffer registers allow loading of data from an 8-bit or 16-bit data bus. The A<sub>0</sub> and A<sub>1</sub> pins select one of four operations:

1. Load the LS buffer register with the data at inputs D<sub>0</sub> to D<sub>7</sub>,
2. Load the MS buffer register with the data at inputs D<sub>8</sub> to D<sub>15</sub>,
3. Load the DAC register with the contents of the MS and LS buffer registers, and,
4. Load the DAC register directly from the data input pins. (See Table 3).

The CS and WR pins must be low to allow data transfer to occur. When direct loading is selected (CS, WR, A<sub>0</sub> and A<sub>1</sub> low), the registers are transparent and the data input pins control the DAC output directly. The other modes of operation allow double buffered loading of the DAC from an 8-bit bus.

These input data pins are also used to program the PROM under control of the PROG pin. This is done in manufacturing, and for normal read-only use the PROG pin should be tied to V<sup>+</sup> (+5V dc).

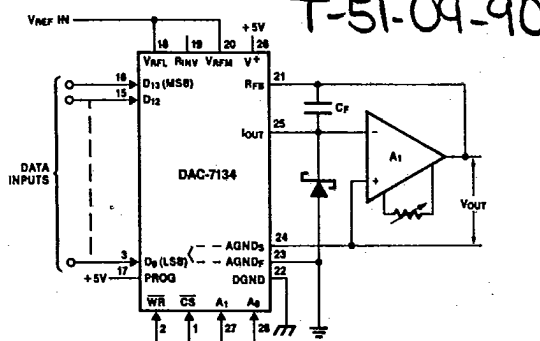

**Table 3. Data Loading Controls**

CONTROL LINES				DAC-7134 OPERATION
A <sub>0</sub>	A <sub>1</sub>	CS	WR	
X	X	X	1	No operation, device not selected
X	X	1	X	No operation, device not selected
0	0	0	0	Load registers from data bus
0	1	0	0	Load LS register from data bus
1	0	0	0	Load MS register from data bus
1	1	0	0	Load DAC register from MS and LS register

Note: Data is latched on low-to-high transitions of either WR or CS.

**UNIPOLAR BINARY OPERATION**

Figure 5 shows a typical circuit configuration for unipolar mode operation using a DAC-7134U. With positive and negative V<sub>REF</sub> values, the circuit is capable of two-quadrant multiplication. Table 4 presents a digital input code/analog output value reference for unipolar mode operation. The Schottky diode (HP5082-2811 or equivalent) protects I<sub>OUT</sub> from negative excursions which could damage the device, and is only necessary with certain high speed amplifiers.

**Figure 5. Unipolar Binary, Two-Quadrant Multiplying Circuit**

**Table 4. Code Table—Unipolar Binary Operation**

DIGITAL INPUT		ANALOG OUTPUT
MSB	LSB	
1 1 1	1 1 1	- (V <sub>REF</sub> + 1 LSB)
1 1 0	0 0 0	- 0.75 X (V <sub>REF</sub> )
1 0 0	0 0 0	- 0.5 X (V <sub>REF</sub> )
0 1 0	0 0 0	- 0.25 X (V <sub>REF</sub> )
0 0 0	0 0 0	0

**Zero Offset Adjustment**  
(See Figure 5)

1. Connect all data inputs and WR, CS, A<sub>0</sub> and A<sub>1</sub> to DGND. (Connect pins 1 through 16, 27, and 28 to pin 22).
2. Adjust the offset zero-adjust trim-pot of op-amp A2, if used, for a maximum of 0V ±50µV dc at AGND<sub>S</sub>.
3. Adjust the offset zero-adjust trim-pot of output op-amp A1 for a maximum of 0V ±50µV dc at V<sub>OUT</sub>.

**Gain Adjustment (Optional)**

1. Connect all data inputs (pins 1 through 16) to V<sup>+</sup> (pin 26). Connect CS, WR, A<sub>1</sub> and A<sub>0</sub> (pins 1, 2, 27, and 28 respectively) to DGND (pin 22).
2. Monitor V<sub>OUT</sub> for a -(V<sub>REF</sub> + 1 LSB) reading.
3. To decrease V<sub>OUT</sub>, connect a series resistor of 100 ohms or less between the reference voltage and the V<sub>RFB</sub> and V<sub>RFL</sub> terminals (pins 20 and 18).
4. To increase V<sub>OUT</sub>, connect a series resistor of 100 ohms or less between OP-AMP A1's output and the R<sub>FB</sub> terminal (pin 21).

For applications where the output reference ground point is established somewhere other than at the DAC, a circuit similar to that shown in Figure 6 could be used. Here, op-amp A2 removes the slight error due to IR voltage drop between the internal analog ground node and the external ground connection. For 13-bit or lower accuracy, omit A2 and connect AGND<sub>F</sub> and AGND<sub>S</sub> directly to ground through as low a resistance as possible.

T-51-09-90

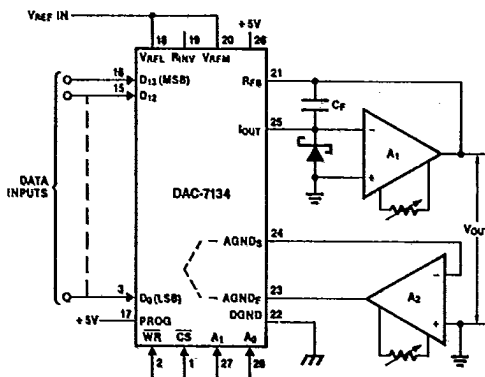

Figure 6. Unipolar Binary Operation with Forced Ground

Table 5. Code Table—Bipolar (2's complement) Operation

DIGITAL INPUT		ANALOG OUTPUT	
MSB	LSB	+VREF	-VREF
0 1 1	1 1 1	+VREF-1LSB	-VREF + 1LSB
0 1 0	0 0 0	0.5(+VREF)	0.5(-VREF)
0 0 0	0 0 0	0	0
1 1 0	0 0 0	0.5(-VREF)	0.5(+VREF)
1 0 0	0 0 0	-VREF	+VREF

**Offset Adjustment**  
(See Figure 7)

1. Connect all data inputs and  $\overline{WR}$ ,  $\overline{CS}$ ,  $A_0$  and  $A_1$  to DGND. (Connect pins 1 through 16, 27, and 28 to pin 22).
2. Set data to 00000...00. Adjust the offset zero adjust trim-pot of output op-amp A1 for a maximum of  $0V \pm 50\mu V$  dc  $V_{OUT}$ .
3. Connect  $D_{13}$  (MSB, pin 16) data input to  $V^+$  (pin 26).
4. Adjust the offset zero-adjust trim-pot of op-amp A2 for a maximum of  $0V \pm 50\mu V$  dc at the  $R_{INV}$  terminal (pin 19).

2

**BIPOLAR (2's COMPLEMENT) OPERATION**

Figure 7 shows a circuit configuration for bipolar mode operation using a DAC-7134B. Using 2's complement digital input codes and positive and negative reference voltage values, four-quadrant multiplication is obtained. Table 5 lists the digital input codes and their respective analog output values for bipolar mode operation.

Amplifier A2, together with internal resistors  $R_{INV1}$  and  $R_{INV2}$ , forms a simple voltage inverter circuit. The MSB ladder leg sees a reference input of approximately  $-V_{REF}$ , so the MSB's weight is reversed from the polarity of the other bits. In addition, the DAC-7134B's feedback resistance switches to  $2R$  under PROM control.

The resultant bipolar output range is  $+V_{REF}$  to  $(-V_{REF} + 1 \text{ LSB})$ . Again, the grounding arrangement of Figure 6 can be used.

**Gain Adjustment (Optional)**

1. Connect  $\overline{CS}$ ,  $\overline{WR}$ ,  $A_1$  and  $A_0$  (pins 1, 2, 27, and 28 respectively) to DGND (pin 22).
2. Connect  $D_0$  through  $D_{12}$  (pins 3 through 15) to  $V^+$  (pin 26). Connect  $D_{13}$  (MSB, pin 16) to DGND (pin 22).
3. Monitor  $V_{OUT}$  for a  $-V_{REF} + 1 \text{ LSB}$  reading.
4. To increase  $V_{OUT}$ , connect a series resistor of 200 ohms or less between op-amp A1's output and the  $R_{FB}$  terminal (pin 21).
5. To decrease  $V_{OUT}$ , connect a series resistor of 100 ohms or less between the reference voltage and the  $V_{RFL}$  terminal (pin 18).

**APPLICATIONS**

**General Recommendations**

**Ground Loops**

Careful consideration must be given to ground loops in any system with 14-bit accuracy. The current into the analog ground point inside the chip varies significantly with the input code value, and the inevitable resistances between this point and any external connection point can lead to significant voltage drop errors. For this reason, two separate leads are brought out from this point on the IC, and  $AGND_F$  and  $AGND_S$  pins. The varying current should be absorbed through the  $AGND_F$  pin, and the  $AGND_S$  pin will then accurately reflect the voltage on the internal current summing point. Thus, output signals should be referenced to the sense pin  $AGND_S$ , as shown in the various application circuits.

**Power Supplies**

The  $V^+$  (pin 25) power supply should have a low noise level, and no transients exceeding 7 volts. Note that the absolute maximum digital input voltage allowed is  $V^+$ , which therefore must be applied before digital inputs are allowed to go high. Unused digital inputs must be connected to GND or  $V^+$  for proper operation.

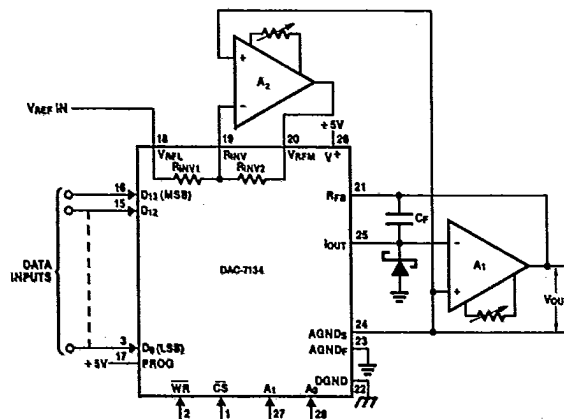

Figure 7. Bipolar (2's Complement), Four-Quadrant Multiplying Circuit

**Operational Amplifier Selection**

To maintain static accuracy, the  $I_{OUT}$  potential must be exactly equal to the  $AGND_S$  potential. Thus, output amplifier selection is critical, in particular low input bias current (less than 2nA), low offset voltage drift (depending on the temperature range) and low offset voltage (less than 25 $\mu$ V) are advisable if the highest accuracy is needed. Maintaining a low input offset over a 0V to 10Vdc range also requires that the output amplifier has a high open loop gain ( $A_{VOL} > 400k$  for effective input offset less than 25 $\mu$ V).

The reference inverting amplifier used in the bipolar mode circuit must also be selected carefully. If 14-bit accuracy is desired without adjustment, low input bias current (less than 1nA), low offset voltage (less than 50 $\mu$ V), and high gain (greater than 400k) are recommended. If a fixed reference voltage is used, the gain requirement can be relaxed. For highest accuracy (better than 13 bits), an additional op-amp may be needed to correct for IR drop on the analog ground line (op-amp  $A_2$  in Figure 6). This op-amp should be selected for low bias current (less than 2nA) and low offset voltage (less than 50 $\mu$ V).

The op-amp requirements can be readily met using an AM-7650 chopper stabilized device. For faster settling time, DATEL's AM-460 or AM-462 can be used with an AM-7650 providing automatic off-set null.

The output amplifier's non-inverting input should be tied directly to  $AGND_S$ . A bias current compensation resistor is of limited use since the output impedance at the summing node depends on the code being converted in an unpredictable way. If gain adjustment is required, low tempco (approximately 50ppm/ $^{\circ}$ C) resistors or trim-pots should be selected.

**PACKAGE DIMENSIONS**

The DAC-7134B and DAC-7134U differ only in the programming instructions. Therefore, the same package dimensions, as shown in Figure 8, apply to both model numbers. The device is available only in a standard 28-pin CERDIP package.

**PACKAGE DIMENSIONS** All dimensions in inches (millimeters)
