# EV2106DQ/DK-00A

## 2.6V to 15V IN, 1.5A OUT Synchronous Buck Converter Evaluation Board

### GENERAL DESCRIPTION

The EV2106DQ/DK-00A is an evaluation board designed to demonstrate the abilities of the MP2106DQ and MP2106DK synchronous buck converters, respectively. It can convert an input voltage with a range of 2.6V to 15V to a lower output voltage from 0.9V while delivering 1.5A to the load. The output voltage is preset to 1.8V, but can be easily be adjusted to other levels from 0.9V.

Fault condition protection includes cycle-by-cycle current limiting, thermal shutdown and under voltage lockout. The part's current mode control, high switching frequency and integrated high-side and low-side power MOSFETs, combined with tiny 10-pin MSOP or QFN packages, provide a solution requiring a minimum of components, board area and cost.

### ELECTRICAL SPECIFICATIONS

Parameter	Symbol	Value	Units
Input Voltage	$V_{IN}$	2.6 to 15	V
Output Current	$I_{LOAD}$	1.5	A

### FEATURES

- Up to 1.5A Continuous Output Current
- Wide 2.6V to 15V Operating Input Range
- Internal Power Switches
- 800KHz Fixed Switching Frequency
- All Ceramic Input and Output Capacitors
- Programmable Soft-Start
- Programmable Input Under Voltage Lockout

### APPLICATIONS

- SOHO Routers, PCMCIA Cards, Mini PCI
- Handheld Computers
- PDAs
- Cellular Phones
- Digital Still and Video Cameras
- Small LCD Displays

"MPS" and "The Future of Analog IC Technology", are Registered Trademarks of Monolithic Power Systems, Inc.

## QUICK START GUIDE

The output voltage of this board is set to 1.8V. The board layout accommodates most commonly used inductors and output capacitors.

1. Attach positive end and negative end of load to OUT and GND pins, respectively.
2. Attach input voltage ( $2.6V \leq V_{IN} \leq 13.5V$ ) and input ground to IN and GND pins, respectively.
3. A pull-up resistor has connected the EN pin to the IN pin, so the MP2106 will startup automatically without applying an external voltage to the EN pin.
4. The output voltage  $V_{OUT}$  can be changed by varying R3. Calculate the new value using the formula:

$$R3 = R4 \times \left( \frac{V_{OUT}}{V_{FB}} - 1 \right)$$

where  $V_{FB} = 0.9V$  and  $R4 = 10k\Omega$ .

For example, for  $V_{OUT} = 2.5V$ :

$$R3 = R4 \times \left( \frac{V_{OUT}}{V_{FB}} - 1 \right) = 10k\Omega \times \left( \frac{2.5V}{0.9V} - 1 \right) = 17.78k\Omega \sim 17.8k\Omega$$

for the closest standard 1% value.

See Maximum Duty Cycle limits to determine allowable output voltages.
