# FUNCTIONAL DESCRIPTIONS

## DIVIDE FACTOR OF DIVIDER

Serial data of binary code is input to Data pin. On rising edge of clock shifts one bit of data into the shift registers. Input data consists of 16-bit data and 1-bit of control data. The control data determines which latch is activated. When control bit is high, 16-bit latch is selected. When low, 6-bit latch and 10-bit latch is selected.

The serial data is input to 16-bit shift registers and 1-bit control register. When load enable is high, the data from the shift register is latched into the programmable reference divider (binary 16-bit programmable reference counter) or programmable divider (binary 6-bit swallow counter and binary 10-bit programmable counter) depending upon a control bit setting.

### STAND-BY MODE

When all zero of 16-bit serial data is input, the MB87014A goes to stand-by mode. During stand-by mode, internal circuit stops operation and  $t_{IN}$  and  $OSC_{IN}$  are forced to high level. Thus, low supply current is achieved. Stand-by mode is released, when the data except all zero data is input.

### SERIAL DATA INPUT TIMING

**Notes:** Data: Serial data input is used for setting divide factor of programmable reference divider or programmable divider.

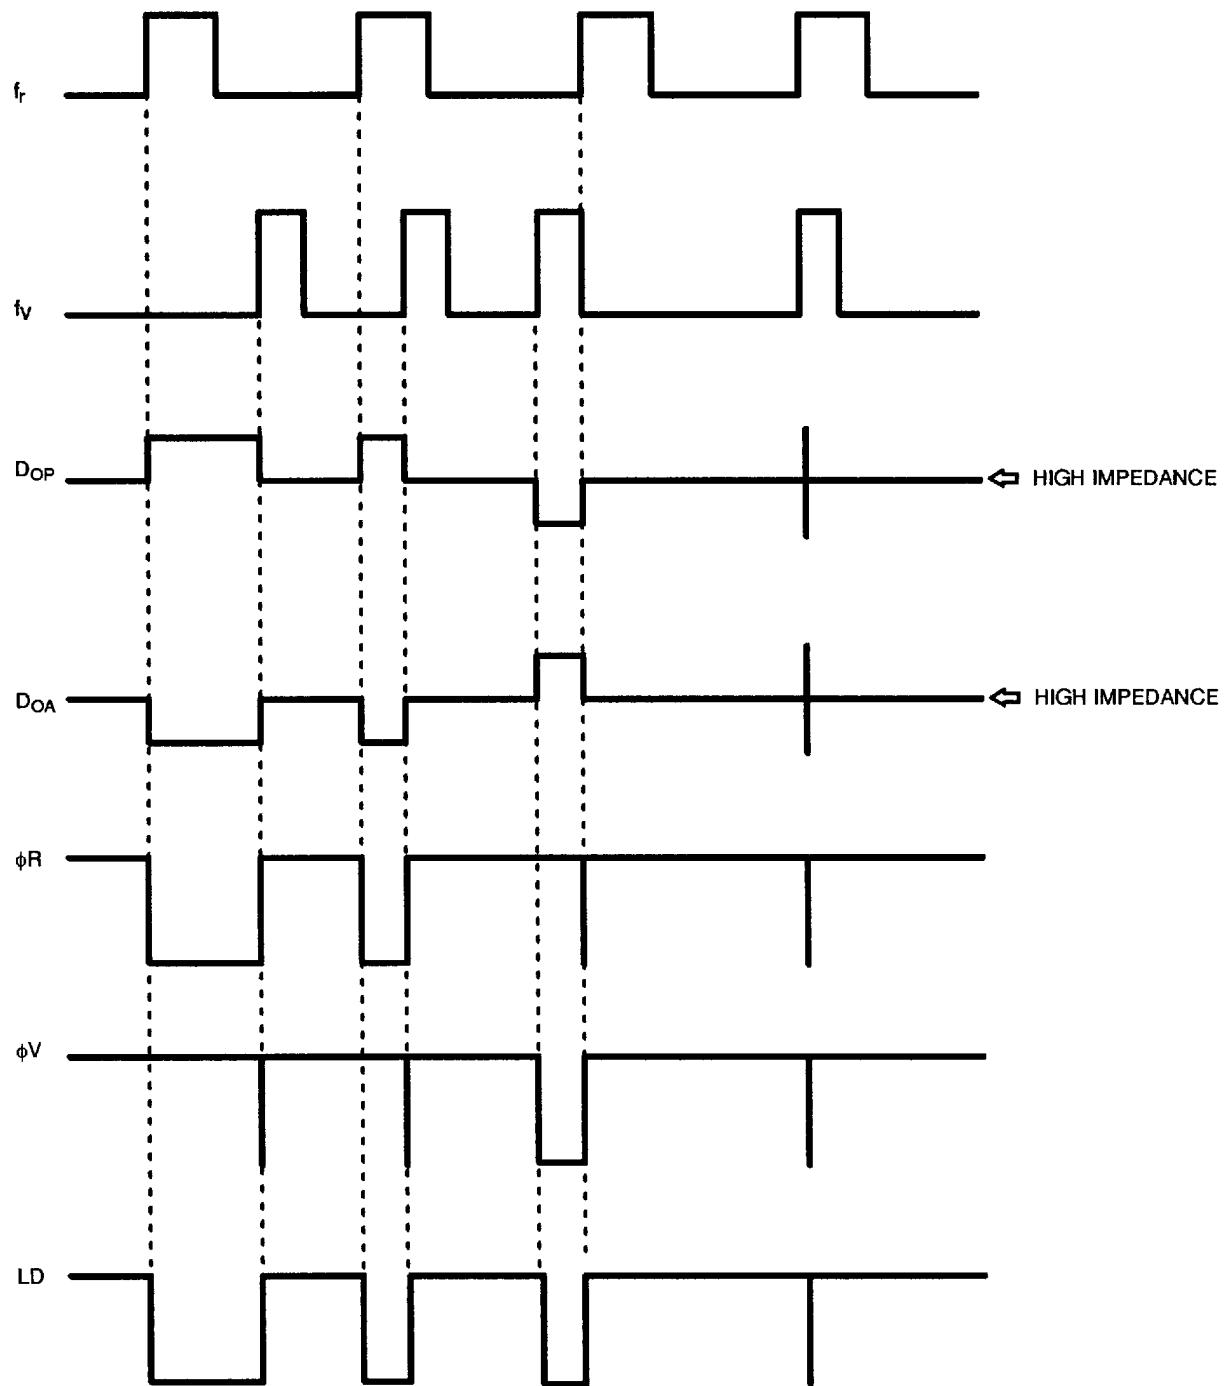

Data is input from MSB and last bit data is control bit.

Control bit is high level when divide factor of programmable reference divider is set. Control bit is set low level when divide factor of programmable divider is set.

Clock: Clock input for 16-bit shift registers and control register. Data is input into internal shift registers by rising edge of the clock.

LE: Load enable input:

When LE is high, the data from shift register is latched into programmable reference divider or programmable divider depending upon the control bit setting.
