

## 4-Channel And 6-Channel High Speed, Auto-direction Sensing Logic Level Translators

The ISL3034E, ISL3035E, ISL3036E 4- and 6-channel bi-directional, auto-direction sensing, level translators provide the required level shifting in multi-voltage systems at data transfer rates up to 100Mbps. The auto-direction sensing feature makes the ISL3034E, ISL3035E, ISL3036E ideally suited for memory-card level translation (or for generic four to six channel level translation) especially if bit-by-bit direction control is desired. The  $V_{CC}$  and  $V_L$  supply voltages set the logic levels on either side of the device. Logic signals present on the IC's  $V_L$  side appear as higher voltage logic signals on the IC's  $V_{CC}$  side and vice versa. The ISL3035E features a CLK\_RET output that returns the same clock signal applied to the CLK\_VL input, but with timing that mimics the data returning from the I/OV<sub>CC</sub> inputs.

The ISL3034E, ISL3035E, ISL3036E operate at full speed with external input drivers that source as little as 4mA output current. Each I/O channel is pulled up to  $V_{CC}$  or  $V_L$  by an internal 30 $\mu$ A current source, allowing the ISL3034E, ISL3035E, ISL3036E to be driven by either push-pull or open-drain drivers.

The ISL3034E and ISL3036E include an enable (EN) input that when driven low places the IC into a low-power shutdown mode, with all I/O lines tri-stated. All versions feature an automatic shutdown mode, that places the part in the same shutdown state when  $V_{CC}$  is less than  $V_L$ . The states of I/OV<sub>CC</sub> and I/OV<sub>L</sub> during shutdown are chosen by selecting the appropriate product (see Table 1).

The ISL3034E, ISL3035E, ISL3036E operate with  $V_{CC}$  voltages from +2.2V to +3.6V and  $V_L$  voltages from +1.35V to +3.2V, making them ideal for data transfer between low-voltage microcontrollers or ASICs and higher voltage components.

**TABLE 1. SUMMARY OF FEATURES**

PART NUMBER	DATA RATE (Mbps)	NUMBER OF CHANNELS	EN PIN?	I/OV <sub>L</sub> SHDN STATE	I/OV <sub>CC</sub> SHDN STATE
ISL3034E	100	6	YES	16.5k $\Omega$ to $V_L$	16.5k $\Omega$ to $V_{CC}$
ISL3035E	100	6	NO	75k $\Omega$ to $V_L$	High Impedance
ISL3036E	100	4	YES	16.5k $\Omega$ to $V_L$	16.5k $\Omega$ to $V_{CC}$

## Features

- Best-In-Class ESD Protection:  $\pm 15$ kV IEC61000-4-2 ESD Protection on ALL Input, Output, and I/O Lines
- 100Mbps Guaranteed Data Rate
- Four (ISL3036) or Six (ISL3034, ISL3035) Bi-directional Channels
- Auto-direction Sensing Eliminates Direction Control Logic Pins
- Enable Input (ISL3034E, ISL3036E) for Logic Control of Low Power SHDN Mode
- Clock Return Output (ISL3035E)
- Compatible with 4mA Input Drivers or Larger
- +1.35V  $\leq V_L \leq$  +3.2V and +2.2V  $\leq V_{CC} \leq$  +3.6V Supply Voltage Range
- Pb-Free (RoHS Compliant)
- 16Ld  $\mu$ TQFN (2.6mmx1.8mm), 16 Ld TQFN (3mmx3mm), and 14 Ld QFN (3.5mmx3.5mm) Packages

## Applications

- Simplifies the Interface Between Two Logic ICs Operating at Different Supply Voltages
- SD Card and MiniSD Card Level Translation
- MMC (Multi Media Card) Level Translation
- Memory Stick Card Level Translation

## Typical Operating Circuit

NOTES:

1. These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
2. These Intersil Pb-free plastic packaged products employ special Pb-free material sets; molding compounds/die attach materials and NiPdAu plate - e4 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.
3. Please refer to TB347 for details on reel specifications.

## Application Information

### Overview

The ISL3034E, ISL3035E, ISL3036E are 100Mbps, bi-directional voltage level translating ICs for multi-supply voltage systems. These products shift lower voltage levels on one interface side (supplied by  $V_L$ ) to a higher voltage level on the other interface side (supplied by  $V_{CC}$ ), or vice versa.  $V_{OH}$  of the  $I/OV_L$  pins tracks the  $V_L$  supply, while  $V_{OH}$  of the  $I/OV_{CC}$  pins tracks the  $V_{CC}$  supply.

These ICs feature bit-by-bit auto-direction sensing to increase flexibility, and to eliminate the need for direction control pins. On chip pull-up current sources in the active mode, and pull-up resistors in SHDN mode, eliminate the need for most external bus resistors. Drivers interfacing with these level translators may be open-drain or push-pull types, and all three versions may also be used for unidirectional level shifting.

The three versions share the same architecture, but the ISL3034E is a general purpose 6-Channel version, while the 6-Channel ISL3035E specifically targets SD Card and other memory card applications. The 4-channel ISL3036 targets nibble and byte based applications, as well as 4-wire SPI interfaces. Power supply ranges allow level shifting between 1.5V, 1.8V, and 2.5V powered devices on the  $V_L$  side to 2.5V, and 3.3V devices on the  $V_{CC}$  side.

### Principles of Operation

When enabled, these level shifters detect transitions on an I/O pin, and drive the appropriate logic level on the corresponding I/O pin on the other "side". If the transition was low-to-high, the channel shifts the voltage up to  $V_{CC}$  (for transitions on an  $I/OV_L$  pin) or down to  $V_L$  (for transitions on an  $I/OV_{CC}$  pin), and then drives the shifted level on the other side. The ISL3035E enables whenever  $V_{CC} > V_L + 200\text{mV}$ , while the ISL3034E and ISL3036E enable if  $EN = 1$  AND  $V_{CC} > V_L + 200\text{mV}$ .

Upon detecting a transition on either I/O pin, that channel's accelerator circuitry actively drives the opposite side's (output) pin to GND or the output's supply rail, and then turns off. Weak hold circuitry then maintains the logic state until the input is 3-stated, or until another active transition occurs on either I/O pin for that channel. Figure 5 shows the simplified block diagram of one level shifting channel. The accelerator circuitry comprises high and low threshold detectors, one shots with level shifters and large output drivers. A transition on one of the  $I/OV_L$  or  $I/OV_{CC}$  pins momentarily defines that pin as an input. When the high or low threshold is crossed, a one-shot fires either the PMOS or NMOS driver, respectively, on the opposite side (effectively the output). These drivers are large enough to quickly drive the output node to its respective supply or to GND. Note that this transition on the "output" trips the transition detector on that pin, firing its accelerator, which feeds back to the "input" to help reinforce slow transitions, such as those from an

**FIGURE 5. ONE CHANNEL SIMPLIFIED SCHEMATIC**  
open-drain type driver. Once the one-shot - and thus the accelerator - times out (approximately 3ns to 4ns), the large output drivers tri-state and the pins are weakly held in the last state by the small NMOS transistor between  $I/OV_L$  and  $I/OV_{CC}$  (for a low) or by the small current sources (for a high). In this static state, the I/O pins are easily overdriven by the next transition from an external driver. Having large pull-up and pull-down devices in the accelerator (vs just an active pull-up) nearly eliminates the concern about the external driver's output impedance, and that impedance's effect on  $V_{OL}$ , fall times and data rate.

The weak pull-up current sources on each I/O pin and the NMOS pass transistors, remain ON whenever the IC is enabled. If a channel's external driver tri-states, the weak pull-up currents either keep the I/O pins high, or if the last state was a low the current sources pull the I/O pins high. In the latter case, each channel's accelerators will once again fire when either the  $I/OV_L$  or the  $I/OV_{CC}$  voltage crosses the accelerator's high threshold level.

### Auto Direction Sensing

Each level translator channel independently and automatically determines the direction of data transfer without any external control signals. As described earlier, a transition on either of the channel's I/O pins momentarily defines that pin as an input, which then translates and drives that input signal to the channel's corresponding pin on the other port (now the output). After a brief period of active driving, both I/O pins return to their weak "hold" mode, where the next transition on either I/O pin determines the direction for the next transfer.

Auto sensing saves valuable processor GPIO pins (three [CLK, CMD, DAT] for SD Card applications, or six for the general purpose hex case), and simplifies the software associated with the peripheral interface.

### Using Open Drain Drivers

These level translators' accelerator based architecture works equally well when driven by push-pull or open drain type drivers (e.g., for the CMD line initialization in MMC

applications). The low static pull-up current is easily overdriven by an active pull-down, and the feedback nature of the accelerators (i.e., the accelerator firing in one direction also triggers the accelerator in the opposite direction) aids the passive pull-up once the input signal passes the accelerator's high threshold. The pull-up current and load capacitance set the input signal rise time, and thus the maximum data rate. For slow data rates the internal pull-up current may suffice, but higher data rates - or more heavily loaded signal lines - may require an external pull-up resistor.

**Using External Bus Resistors**

As mentioned earlier, these level translators incorporate I/O pin pull-up current sources when enabled, and I/O pin pull-up resistors in SHDN (except for the ISL3035E's I/OV<sub>CC</sub> pins). Therefore, external pull-up or pull-down resistors shouldn't be necessary, and aren't recommended, unless using high-speed open drain signaling.

**Power Supplies**

**WIDE SUPPLY RANGE**

These ICs operate from a wide range of supply voltages. V<sub>L</sub> is designed to connect to the supply of 1.5V, 1.8V, and 2.5V powered devices, while V<sub>CC</sub> is targeted for 2.5V, and 3.3V components. Remember that V<sub>CC</sub> must be greater than V<sub>L</sub> for proper operation.

**POWER SUPPLY SEQUENCING**

Either V<sub>CC</sub> or V<sub>L</sub> may be powered up first, but the IC remains in SHDN until V<sub>CC</sub> exceeds V<sub>L</sub> by as much as 200mV. V<sub>L</sub> may exceed V<sub>CC</sub> by as much as 4V without causing any damage.

**I/O PIN INPUT THRESHOLDS VS SUPPLY VOLTAGE**

Even though the "Electrical Specification" table on page 4 shows the I/O pin input thresholds (V<sub>IH</sub>, V<sub>IL</sub>) with a fixed delta from the supplies or GND, the thresholds are better represented as a percentage of the supplies. The typical I/OV<sub>CC</sub> and CLK\_V<sub>CC</sub> V<sub>IH</sub> runs about 55% to 60% of V<sub>CC</sub>, while the corresponding V<sub>IL</sub> runs about 33% of V<sub>CC</sub>. The typical I/OV<sub>L</sub> and CLK\_V<sub>L</sub> V<sub>IH</sub> runs about 60% to 70% of V<sub>L</sub>, while the corresponding V<sub>IL</sub> runs about 25% to 35% of V<sub>L</sub>.

**Low Power SHDN Mode**

This family of level translators features a low power SHDN mode that tri-states all the I/O and output pins, considerably reduces current consumption, and enables any pull-up resistors on a port's I/O pins (see Table 1). The ISL3034E and ISL3036E enter the SHDN mode when the EN input switches low, or automatically when the V<sub>CC</sub> voltage drops below the V<sub>L</sub> voltage. The ISL3035 has no enable pin, so it enters SHDN only if V<sub>CC</sub> drops below V<sub>L</sub>. The V<sub>L</sub> supply powers the EN circuitry.

**ISL3034E and ISL3036E**

The ISL3034E and ISL3036E are general purpose level translators featuring an enable pin, and six or four channels,

respectively. Both products include SHDN mode 16.5kΩ pull-ups on the I/OV<sub>CC</sub> and I/OV<sub>L</sub> pins.

**ISL3035E**

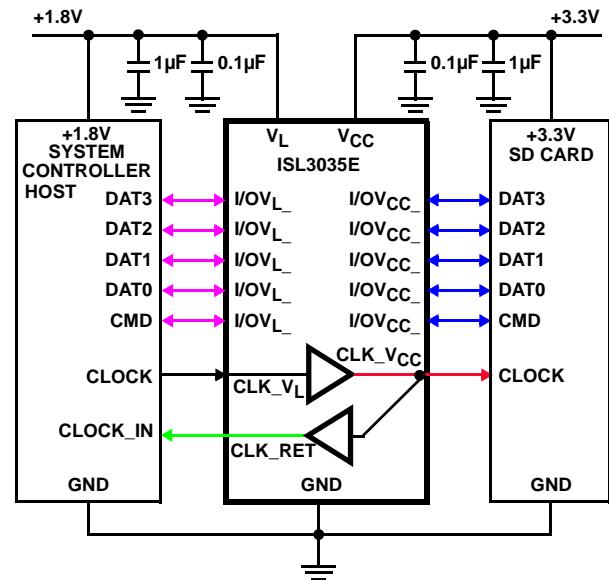

FIGURE 6. ISL3035E IN AN SD CARD APPLICATION

The ISL3035E specifically targets memory card applications, and Figure 6 illustrates its use in an SD Card application. Instead of six general purpose channels, the ISL3035E features five general purpose channels and one dedicated CLK channel. In memory card applications, the CLK channel is a unidirectional signal driven by the host controller and used by the memory card to synchronize data reads and writes. The ISL3035E's CLK channel is unique in that the host CLK applied to the CLK\_V<sub>L</sub> pin routes to the memory card via the CLK\_V<sub>CC</sub> pin, but it also loops back to the host on the CLK\_RET pin. This CLK\_RET signal better mimics the timing of "read" data returned from the memory card (see Figure 21 for signal timing), so using CLK\_RET as the host's input CLK improves the CLK to data timing relationship.

CLK\_RET is strictly an output, and CLK\_V<sub>L</sub> is strictly an input. If an ISL3035E application needs a sixth I/O channel then the user needs to connect CLK\_V<sub>L</sub> and CLK\_RET together. Connected this way, the combination channel has the same architecture as the other I/O channels. Both CLK\_RET and CLK\_V<sub>L</sub> have equivalent pull-up current sources and SHDN pull-up resistors, so connecting these two pins together doubles the pull-up current in either mode.

The bit-by-bit auto direction control eliminates the need for GPIO signals to control the flow of data on the CMD and DAT lines.

The ISL3035E has no enable pin, so it only enters the low power SHDN mode when V<sub>CC</sub> drops below V<sub>L</sub>. There are no SHDN pull-up resistors on the I/OV<sub>CC</sub> and CLK\_V<sub>CC</sub> pins, but there are 75kΩ pull-ups on the I/OV<sub>L</sub>, CLK\_V<sub>L</sub>, and CLK\_RET pins.

**Best-in-Class ESD Protection**

All pins on these devices include class 3 (>12kV) Human Body Model (HBM) ESD protection structures, but the input and I/O pins incorporate advanced structures allowing them to survive ESD events in excess of ±15kV HBM and ±15kV to IEC61000-4-2. The I/OV<sub>CC</sub> pins are particularly vulnerable to ESD damage because they typically connect to an exposed port on the exterior of the finished product. Simply touching the port pins, or connecting a memory card, can cause an ESD event that might destroy unprotected ICs. These new ESD structures protect the device whether or not it is powered up and without degrading the level shifting performance. This built-in ESD protection eliminates the need for board level protection structures (e.g., transient suppression diodes) and the associated, undesirable capacitive load they present. To ensure the full benefit of the built-in ESD protection, connect the IC's GND pin directly to a low impedance GND plane.

**IEC61000-4-2 Testing**

The IEC61000 test method applies to finished equipment, rather than to an individual IC. Therefore, the pins most likely to suffer an ESD event are those that are exposed to the outside world (typically I/OV<sub>CC</sub> pins in memory card applications) but the ISL3034E, ISL3035E, and ISL3036E feature IEC61000 ESD protection on all logic and I/O pins (both I/OV<sub>L</sub> and I/OV<sub>CC</sub>, as well as CLK pins). Unlike HBM and MM methods which only test each pin-to-pin combination without applying power, IEC61000 testing is also performed with the IC in its typical application

configuration (power applied). The IEC61000 standard's lower current limiting resistor coupled with the larger charge storage capacitor yields a test that is much more severe than the HBM test. The extra ESD protection built into these devices' pins allows the design of equipment meeting level 4 criteria without the need for additional board level protection.

**AIR-GAP DISCHARGE TEST METHOD**

For this test method, a charged probe tip moves toward the IC pin until the voltage arcs to it. The current waveform delivered to the IC pin depends on approach speed, humidity, temperature, etc., so it is difficult to obtain repeatable results. All the EN, CLK, and I/O pins withstand ±15kV air-gap discharges, relative to GND.

**CONTACT DISCHARGE TEST METHOD**

During the contact discharge test, the probe contacts the tested pin before the probe tip is energized, thereby eliminating the variables associated with the air-gap discharge. The result is a more repeatable and predictable test, but equipment limits prevent testing devices at voltages higher than ±9kV. Devices in this family survive ±9kV contact discharges (relative to the GND pin) on the EN, CLK, and I/O pins.

**Layout and Decoupling Considerations**

These level translators' high data rates and fast signal transitions require that the accelerators have high transient currents. Thus, short, low inductance supply traces and decoupling within 1/8th inch of the IC are imperative with very low impedance GND return paths.

**Typical Performance Curves**

V<sub>CC</sub> = 3.3V, V<sub>L</sub> = 1.8V, C<sub>L</sub> = 15pF, R<sub>SOURCE</sub> = 150Ω, Data Rate = 100Mbps, push-pull driver, T<sub>A</sub> = +25°C; Unless Otherwise Specified.

NOTES:

1. Dimensioning and tolerancing conform to ASME Y14.5-1994.
2. N is the number of terminals.
3. Nd and Ne refer to the number of terminals on D and E side, respectively.
4. All dimensions are in millimeters. Angles are in degrees.
5. Dimension b applies to the metallized terminal and is measured between 0.15mm and 0.30mm from the terminal tip.
6. The configuration of the pin #1 identifier is optional, but must be located within the zone indicated. The pin #1 identifier may be either a mold or mark feature.
7. Maximum package warpage is 0.05mm.
8. Maximum allowable burrs is 0.076mm in all directions.
9. JEDEC Reference MO-255.
10. For additional information, to assist with the PCB Land Pattern Design effort, see Intersil Technical Brief TB389.
