

## Green-Mode PWM Controller with Integrated Protections and Adjustable OLP Delay Time

REV: 04

### General Description

The LD7530/LD7530A are specifically designed for the low total system cost by integrating many functions, protections, and the EMI-improved solution in a tiny SOT-26 package which usually need a lot of extra components or circuits on the general designs.

Furthermore, the LD7530/7530A features green mode operation, leading edge blanking time, internal slope compensation and adjustable over load protection (OLP) delay time to minimize the component counts for switching power supply.

And to satisfy different designs, 2 versions of OVP levels are implemented as ---

- LD7530 ---  $28.0V \pm 1.2V$ .
- LD7530A ---  $21.0V \pm 1.2V$ .

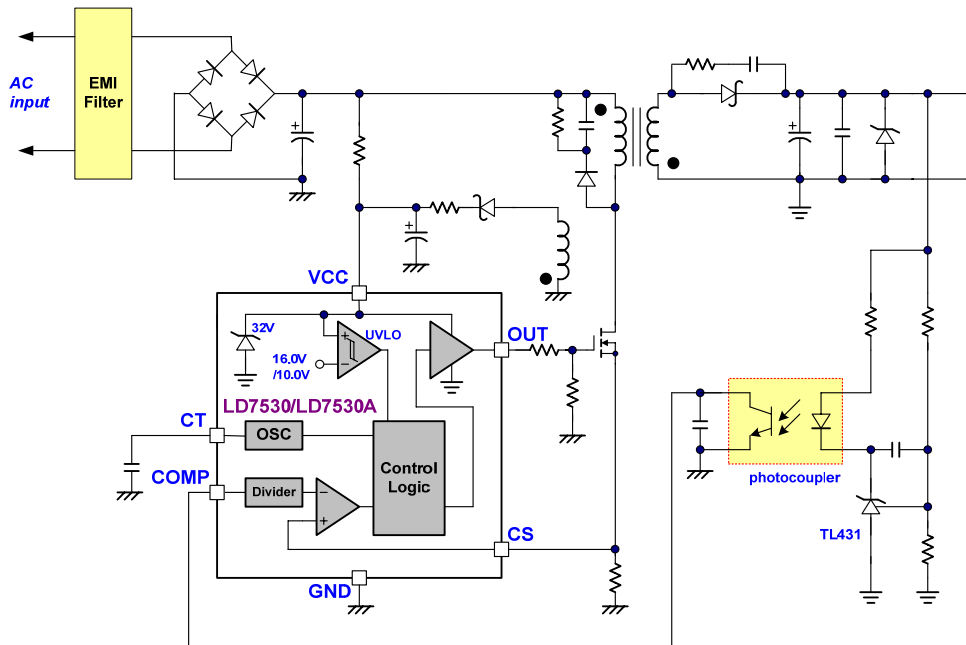

### Features

- High-Voltage CMOS Process with Excellent ESD protection
- Very Low Startup Current ( $<20\mu A$ )
- Current Mode Control
- Non-audible-noise Green Mode Control
- UVLO (Under Voltage Lockout)
- LEB (Leading-Edge Blanking) on CS Pin
- Internal Slope Compensation
- OVP (Over Voltage Protection) on Vcc Pin
- OLP (Over Load Protection)
- 300mA Driving Capability
- Adjustable OLP Delay Time

### Applications

- Switching AC/DC Adaptor and Battery Charger
- Open Frame Switching Power Supply

### Typical Application

Note: The LD7530 and LD7530A are ROHS compliant/ Green Package.

## Pin Descriptions

PIN (SOT-26)	PIN (DIP-8)	NAME	FUNCTION
1	8	GND	Ground
2	7	COMP	Voltage feedback pin (same as the COMP pin in UC384X), by connecting a photo-coupler to close the control loop and achieve the regulation.
3	5	CT	This pin is to program the frequency of the low frequency timer. By connecting a capacitor to ground to set the OLP delay time.
4	4	CS	Current sense pin, connect to sense the MOSFET current
5	2	VCC	Supply voltage pin
6	1	OUT	Gate drive output to drive the external MOSFET

**Block Diagram**

## Absolute Maximum Ratings

Supply Voltage VCC.....	30V
COMP, CT, CS.....	-0.3 ~7V
Junction Temperature.....	150°C
Operating Ambient Temperature.....	-40°C to 85°C
Storage Temperature Range.....	-65°C to 150°C
Package Thermal Resistance (SOT-26).....	250°C/W
Package Thermal Resistance (DIP-8).....	100°C/W
Power Dissipation (SOT-26, at Ambient Temperature = 85°C).....	250mW
Power Dissipation (DIP-8, at Ambient Temperature = 85°C).....	650mW
Lead temperature (Soldering, 10sec).....	260°C
ESD Voltage Protection, Human Body Model.....	2.5 KV
ESD Voltage Protection, Machine Model.....	250 V
Gate Output Current.....	300mA

### Caution:

Stresses beyond the ratings specified in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

## Recommended Operating Conditions

Item	Min.	Max.	Unit
Supply Voltage Vcc (LD7530)	11	25	V
Supply Voltage Vcc (LD7530A)	11	18	V
CT Value	0.047	0.1	μF

## Electrical Characteristics

( $T_A = +25^\circ\text{C}$  unless otherwise stated,  $V_{CC}=15.0\text{V}$ )

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
<b>Supply Voltage (Vcc Pin)</b>					
Startup Current			8	20	$\mu\text{A}$
Operating Current (with 1nF load on OUT pin)	$V_{\text{COMP}}=0\text{V}$		2.0	3.0	$\text{mA}$
	$V_{\text{COMP}}=3\text{V}$		2.5		$\text{mA}$

## Application Information

### Operation Overview

The LD7530/LD7530A meet the green-power requirement and is intended for the use in those modern switching power suppliers and adaptors which demand higher power efficiency and power-saving. It integrated more functions to reduce the external components counts and the size. Its major features are described as below.

### Under Voltage Lockout (UVLO)

An UVLO comparator is implemented in it to detect the voltage on the VCC pin. It would assure the supply voltage enough to turn on the LD7530/LD7530A PWM controllers and further to drive the power MOSFET. As shown in Fig. 13, a hysteresis is built in to prevent the shutdown from the voltage dip during startup. The turn-on and turn-off threshold level are set at 16.0V and 10.0V, respectively.

Fig. 13

### Startup Current and Startup Circuit

The typical startup circuit to generate the LD7530/LD7530A Vcc is shown in Fig. 14. During the startup transient, the Vcc is lower than the UVLO threshold thus there is no gate pulse produced from LD7530/LD7530A to drive power MOSFET. Therefore, the current through R1 will provide the startup current and to charge the capacitor C1. Whenever the Vcc voltage is high enough to turn on the LD7530/LD7530A and further to deliver the gate drive signal, the supply current is provided from the auxiliary winding of the transformer. Lower startup current requirement on the

PWM controller will help to increase the value of R1 and then reduce the power consumption on R1. By using CMOS process and the special circuit design, the maximum startup current of LD7530/LD7530A is only 20μA.

If a higher resistance value of the R1 is chosen, it usually takes more time to start up. To carefully select the value of R1 and C1 will optimize the power consumption and startup time.

Fig. 14

### Current Sensing and Leading-edge Blanking

The typical current mode of PWM controller feedbacks both current signal and voltage signal to close the control loop and achieve regulation. As shown in Fig. 15, the LD7530/LD7530A detect the primary MOSFET current from the CS pin, which is not only for the peak current mode control but also for the pulse-by-pulse current limit. The maximum voltage threshold of the current sensing pin is set at 0.85V. From above, the MOSFET peak current can be obtained from below.

$$I_{PEAK(MAX)} = \frac{0.85V}{R_S}$$

Fig. 15

A 200nS leading-edge blanking (LEB) time is included in the input of CS pin to prevent the false-trigger from the current spike. In the low power application, if the total pulse width of the turn-on spikes is less than 200nS and the negative spike on the CS pin doesn't exceed -0.3V, it could eliminated the R-C filter (as shown in the figure16).

However, the total pulse width of the turn-on spike is decided by the output power, circuit design and PCB layout. It is strongly recommended to adopt a smaller R-C filter (as shown in figure 17) for higher power application to avoid the CS pin being damaged by the negative turn-on spike.

### Output Stage and Maximum Duty-Cycle

An output stage of a CMOS buffer, with typical 300mA driving capability, is incorporated to drive a power MOSFET directly. And the maximum duty-cycle of LD7530/LD7530A is limited to 75% to avoid the transformer saturation.

### Voltage Feedback Loop

The voltage feedback signal is provided from the TL431 at the secondary side through the photo-coupler to the COMP pin of the LD7530/LD7530A. Similar to UC3842, the LD7530/LD7530A would carry 2 diodes voltage offset at the stage to feed the voltage divider at the ratio of 1/3, that is,

$$V_{-(PWM_{COMPARATOR})} = \frac{1}{3} \times (V_{COMP} - 2V_F)$$

A pull-high resistor is embedded internally and can be eliminated externally.

Fig. 16

Fig. 17

### Oscillator and Switching Frequency

The switching frequency of LD7530/LD7530A is fixed as 65 KHz internally to provide the optimized operations by considering the EMI performance, thermal treatment, component sizes and transformer design.

## Internal Slope Compensation

In the conventional application, the problem of the stability is a critical issue for current mode controlling, when it operates in higher than 50% of the duty-cycle. As UC384X, It takes slope compensation from injecting the ramp signal of the RT/CT pin through a coupling capacitor. It therefore requires no extra design for the LD7530/LD7530A since it has integrated it already.

## On/Off Control

The LD7530/LD7530A can be turned off by pulling COMP pin lower than 1.2V. The gate output pin of the LD7530/LD7530A will be disabled immediately under such condition. The off-mode can be released when the pull-low signal is removed.

## Dual-Oscillator Green-Mode Operation

There are many different topologies has been implemented in different chips for the green-mode or power saving requirements such as "burst-mode control", "skipping-cycle mode", "variable off-time control"...etc. The basic operation theory of all these approaches intended to reduce the switching cycles under light-load or no-load condition either by skipping some switching pulses or reduce the switching frequency.

What LD7530/LD7530A use to implement the power-saving operation is Leadtrend Technology's own IP. By using this dual-oscillator control, the green-mode frequency can be well controlled and further to avoid the generation of audible noise.

## OVP (Over Voltage Protection) on Vcc

The  $V_{GS}$  ratings of the nowadays power MOSFETs are often limited up to max. 30V. To prevent the  $V_{GS}$  from the fault condition, LD7530/LD7530A are implemented an OVP function on Vcc. Whenever the Vcc voltage is higher than the OVP threshold voltage, the output gate drive circuit will be shutdown simultaneously thus to stop the switching of the power MOSFET until the next UVLO(on).

The Vcc OVP function in LD7530/LD7530A is an auto-recovery type protection. If the OVP condition, usually caused by the feedback loop opened, is not released, the Vcc will tripped the OVP level again and re-shutdown the output. The Vcc is working as a hiccup mode. The figure 18 shows its operation.

On the other hand, if the OVP condition is removed, the Vcc level will get back to normal level and the output will automatically return to the normal operation.

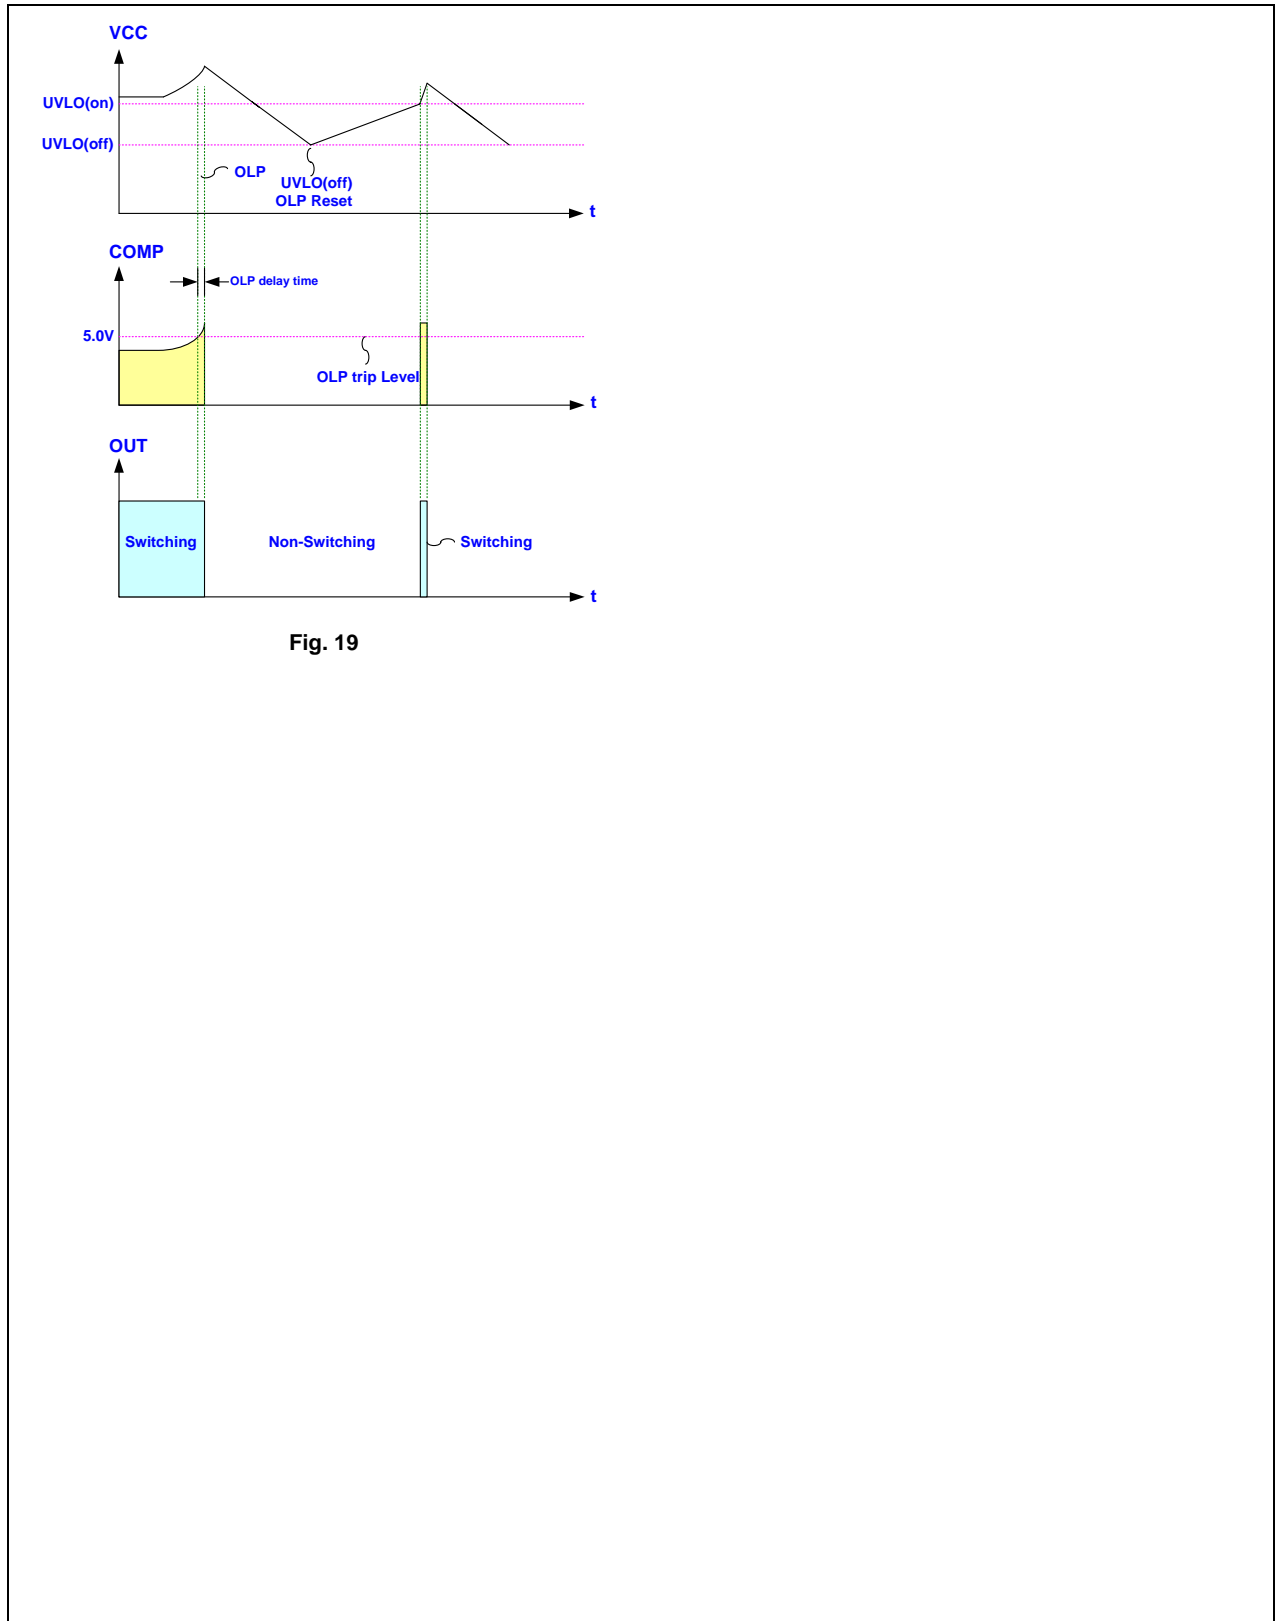

Fig. 18

## Over Load Protection (OLP)

To protect the circuit from being damaged under over load condition or short condition, a smart OLP function is implemented in the LD7530/LD7530A. The figure 19 shows the waveforms of the OLP operation. In this case, the feedback system will force the voltage loop proceed toward the saturation and then pull up the voltage on COMP pin ( $V_{COMP}$ ). Whenever the  $V_{COMP}$  trips up to the OLP threshold 5V and stays longer than the OLP delay time, the protection will activate and then turn off the gate output to stop the switching of power circuit. The OLP delay time, set by CT pin, is to prevent the false trigger from the power-on and turn-off transient. Higher CT value will generate longer OLP delay time. For the recommended CT value, the OLP delay time is around 90mS when  $CT=0.1\mu F$  and will be around 50mS if  $CT=0.047\mu F$ .

By such protection mechanism, the average input power can be reduced to very low level so that the component temperature and stress can be controlled within the safe operating area.

**Fig. 19**
