

Description

The μPD70008 and μPD70008A are power saving, high performance, general purpose 8-bit microprocessor. It is a CMOS-process part with a standby mode that greatly reduces power consumption.

Features

- High performance μPD780 instruction set
- Instruction cycle:
 1 μs at 4 MHz (μPD70008, μPD70008A-4)
 0.66 μs at 6 MHz (μPD70008A-6)
- Direct addressing of up to 64 K bytes of memory
- Memory refresh function
- Interrupt functions:
 – Maskable external interrupt (INT)
 – Nonmaskable external interrupt (NMI)
- Low-power standby mode (HALT)
- CMOS standby mode (HALT)
- Single power supply

Ordering Information

Part Number	Package Type	Max Frequency of Operation
μPD70008C	40-pin plastic DIP	4 MHz
μPD70008AC-4	40-pin plastic DIP	4 MHz
μPD70008AC-6	40-pin plastic DIP	6 MHz
μPD70008AG-4	44-pin plastic miniflat	4 MHz
μPD70008AG-6	44-pin plastic miniflat	6 MHz
μPD70008AL-6	44-pin PLCC	6 MHz

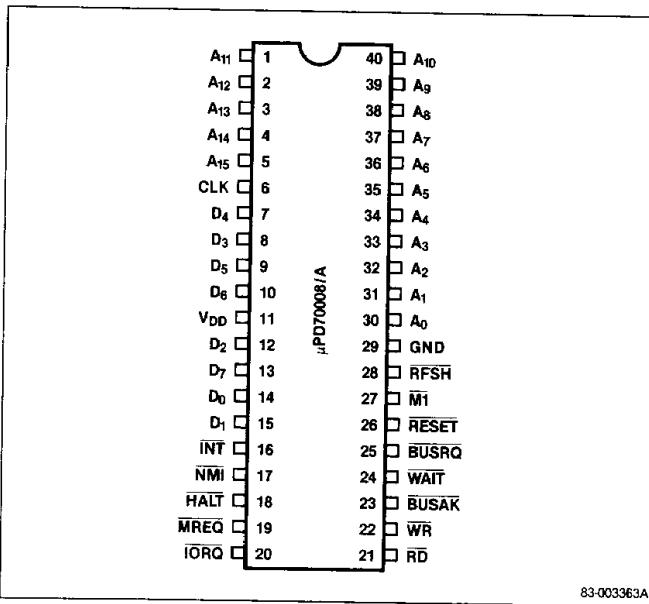

Absolute Maximum Ratings

T _A = 25°C	
Power supply voltage, V _{DD}	-0.3 V to +7 V
Input voltage, V _{IN}	-0.3 V to V _{DD} + 0.3 V
Output voltage, V _O	-0.3 V to V _{DD} + 0.3 V
Operating temperature, T _{OPT}	
μPD70008	-10°C to +70°C
μPD70008A	-45°C to +85°C
Storage temperature, T _{STG}	-65°C to +150°C

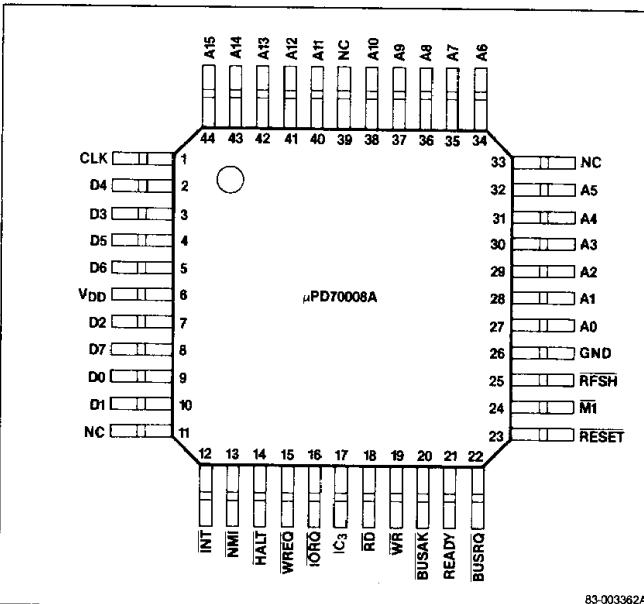

Comment: Exposing the device to stresses above those listed in Absolute Maximum Ratings could cause permanent damage. The device is not meant to be operated under conditions outside the limits described in the operational sections of the specification. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Pin Configurations

44-Pin Plastic Miniflat

Pin Identification**40-Pin Plastic DIP**

No.	Symbol	Function
1-5	A ₁₁ -A ₁₅	Address bus, high bits, outputs
6	CLK	Clock input
7-10	D ₃ -D ₆	Data bus, bits 3-6, inputs /outputs
11	V _{DD}	Power supply
12	D ₂	Data bus, bit 2, input /output
13	D ₇	Data bus, bit 7, input /output
14, 15	D ₀ , D ₁	Data bus, bits 0, 1, inputs /outputs
16	INT	Interrupt input
17	NMI	Nonmaskable interrupt input
18	HALT	Halt / standby mode output
19	MREQ	Memory request output
20	IORQ	I/O request output
21	RD	Read strobe output
22	WR	Write strobe output
23	BUSAK	Bus acknowledge output
24	WAIT	Wait input
25	BUSRQ	Bus request input
26	RESET	Reset input
27	M1	Machine cycle 1 output
28	RFSH	Refresh request output
29	GND	Ground
30-40	A ₀ -A ₁₀	Address bus, low bits, outputs

Pin Functions**A₁₅-A₀ (Address Bus)**

These three-state output pins form a 16-bit address bus for addressing memory or peripheral devices. The address bus enters the high impedance state when bus acknowledge is active. In the standby mode, these pins output high- or low-level signals.

D₇-D₀ (Data Bus)

These three-state pins form an 8-bit bidirectional data bus. On this bus data is transferred between the μ PD70008/A and memory or peripheral devices. This bus enters the high impedance state when bus acknowledge is active. In the standby mode, these pins are high-level.

INT (Interrupt)

This pin is an active-low interrupt input which can be masked by software. NMI has a lower priority than NMI and BUSRQ. INT releases the standby mode.

44-Pin Plastic Miniflat

No.	Symbol	Function
40-44	A ₁₁ -A ₁₅	Address bus, high bits, outputs
1	CLK	Clock input
2-5	D ₃ -D ₆	Data bus, bits 3-6, inputs /outputs
6	V _{DD}	Power supply
7	D ₂	Data bus, bit 2, input /output
8	D ₇	Data bus, bit 7, input /output
9-10	D ₀ , D ₁	Data bus, bits 0, 1, inputs /outputs
12	INT	Interrupt input
13	NMI	Nonmaskable interrupt input
14	HALT	Halt / standby mode output
15	MREQ	Memory request output
16	IORQ	I/O request output
18	RD	Read strobe output
19	WR	Write strobe output
20	BUSAK	Bus acknowledge output
21	WAIT	Wait input
22	BUSRQ	Bus request input
23	RESET	Reset input
24	M1	Machine cycle 1 output
25	RFSH	Refresh request output
26	GND	Ground
28-32, 34-38	A ₀ -A ₁₀	Address bus, low bits, outputs
17	IC	Internally connected
11, 33, 39	NC	Not connected

NMI (Nonmaskable Interrupt)

This pin inputs an interrupt which is not maskable by software. NMI is active-low in the μ PD70008, and is falling edge triggered in the μ PD70008A. NMI has a higher priority than INT, but a lower priority than BUSRQ and RESET. NMI releases the standby mode.

MREQ (Memory Request)

This three-state pin is an active-low output. The μ PD70008/A asserts MREQ to indicate that the information on the address bus is a memory address. This pin enters the high impedance state when bus acknowledge is active. MREQ is inactive (high) in the standby mode.

Pin Functions (cont)**IORQ (I/O Request)**

This three-state pin is an active-low output. The μPD70008/A asserts IORQ to indicate that the information on the address bus is a peripheral device address. IORQ is also asserted during a maskable interrupt service to request the interrupting device to output its interrupt vector to the data bus. This pin enters the high impedance state when bus acknowledge is active. IORQ is inactive (high) in the standby mode.

RD (Read Strobe)

This three-state active-low output provides a read strobe for the memory and peripheral devices. The pin enters the high impedance state when the bus acknowledge is active. RD is inactive (high) in the standby mode.

WR (Write Strobe)

This three-state active-low output provides a write strobe for the memory and peripheral devices. This pin enters the high impedance state when bus acknowledge is active. WR is inactive (high) in the standby mode.

BUSRQ (Bus Request)

This is an active-low input. Peripheral devices assert BUSRQ to request the μPD70008/A to release control of the address bus (A₁₅-A₀), data bus (D₇-D₀) and control bus (MREQ, IORQ, RD and WR) and assert bus acknowledge. BUSRQ has a higher priority than either INT or NMI, but is lower in priority than RESET. BUSRQ will temporarily suspend the standby mode. The μPD70008/A leaves standby mode when BUSRQ is asserted, but returns to the standby mode when BUSRQ is released.

BUSAK (Bus Acknowledge)

This active-low output indicates that the data bus (D₇-D₀), address bus (A₁₅-A₀), and control bus (MREQ, IORQ, RD and WR) have entered the high impedance state. This releases the buses from CPU control and makes them available to the peripheral devices for data exchange. This state cannot be released by NMI or INT, but responds only to RESET or the release of BUSRQ.

HALT (Halt/Standby Mode)

This active-low output is asserted after the halt command has been executed and indicates that the μPD70008/A has entered the standby mode.

WAIT (Wait)

This pin is an active-low input. Memory and peripheral devices assert this signal to increase read or write access time. When WAIT is asserted, the μPD70008/A inserts wait states (TW) into the machine cycle until WAIT is released.

RESET (Reset)

This active-low input is used to reset the μPD70008/A. The standby mode is released on Reset. Reset has the highest priority.

INTI < NMI < BUSRQ < RESET

3

RFSH (Refresh Request)

This pin is an active-low output. The μPD70008/A asserts RFSH to trigger the external memory refresh operation. When RFSH is low, the lower seven bits of the address bus (A₆-A₀) are a refresh address. This pin is inactive (high) in the standby mode.

M1 (Machine Cycle 1)

This pin is an active-low output. When M1 is asserted, it indicates that the μPD70008/A is in the opcode fetch cycle, M1.

CLK (Clock)

This pin is the system clock input.

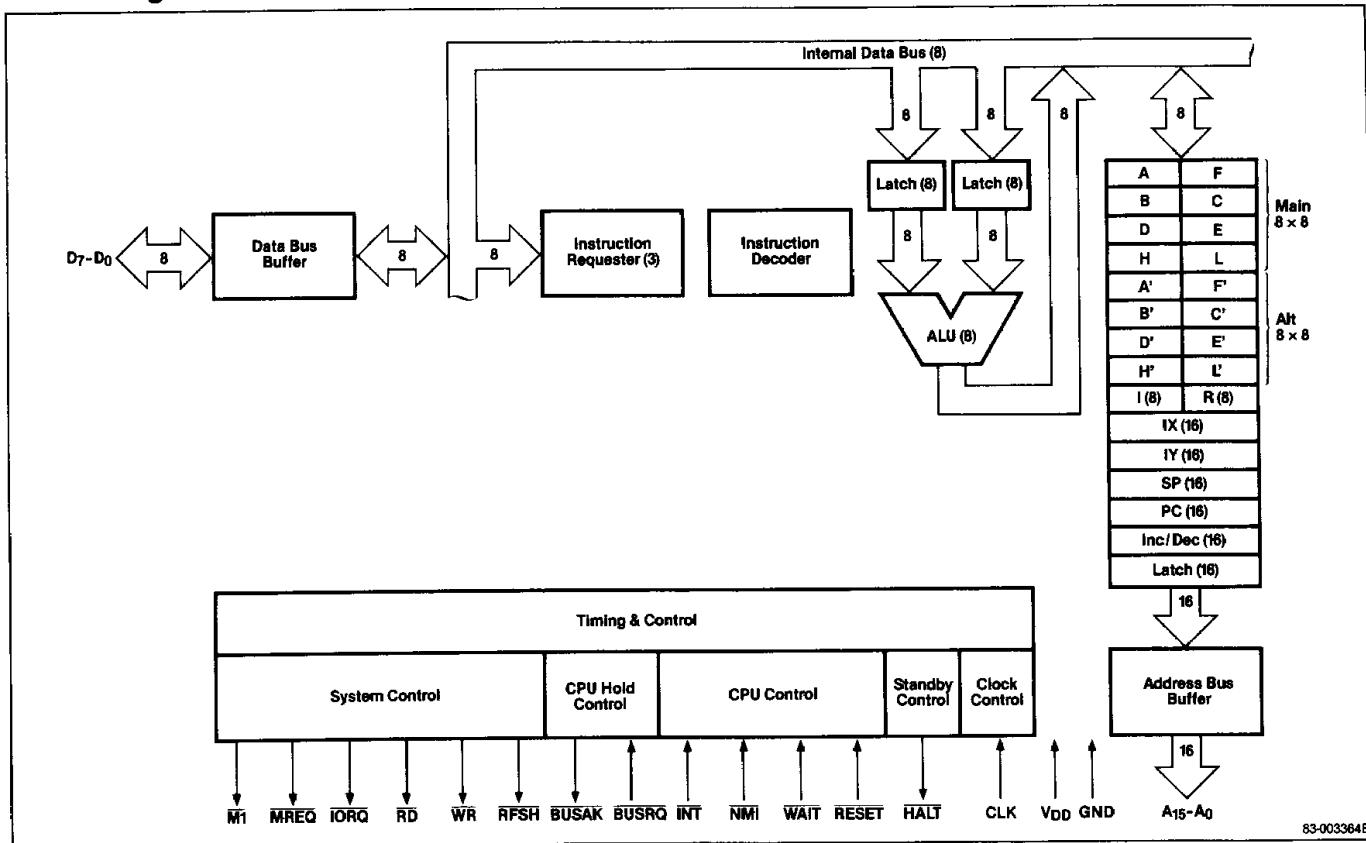

VDD (Power Supply)

This pin is the +5 V power supply input.

GND (Ground)

This pin is the ground pin.

	RD delay from CLK \downarrow to RD high	t_{DKFRH}		85		70	ns	$C_L = 100\text{ pF}$

Note:

(1) $t_{CYK} = t_{KKH} + t_{KKL} + t_{KR} + t_{KF}$

(2) $t_{SAM} = t_{KKH} + t_{KF} - 65$

(3) $t_{HRA} = t_{KKL} + t_{HR} - 50$

(4) $t_{FCA} = t_{KKL} + t_{KR} - 45$

(5) $t_{FCD} = t_{KKL} + t_{KR} - 70$

(6) $t_{MMH} = t_{KKH} + t_{KF} - 20$

(7) $t_{SM1I} = 2t_{CYK} + t_{KKH} + t_{KF} - 65$

(8) $t_{CYK} = t_{KKH} + t_{KKL} + t_{KR} + t_{KF}$

(9) $t_{SAM} = t_{KKH} + t_{KF} - 50$

(10) $t_{SAI} = t_{CYK} - 55$

(11) $t_{HRA} = t_{KKL} + t_{KR} - 50$

(12) $t_{FCA} = t_{KKL} + t_{KR} - 40$

(13) $t_{SMDW} = t_{CYK} - 140$

(14) $t_{SIDW} = t_{KKL} + t_{KR} - 140$

(15) $t_{FCD} = t_{KKL} + t_{KR} - 55$

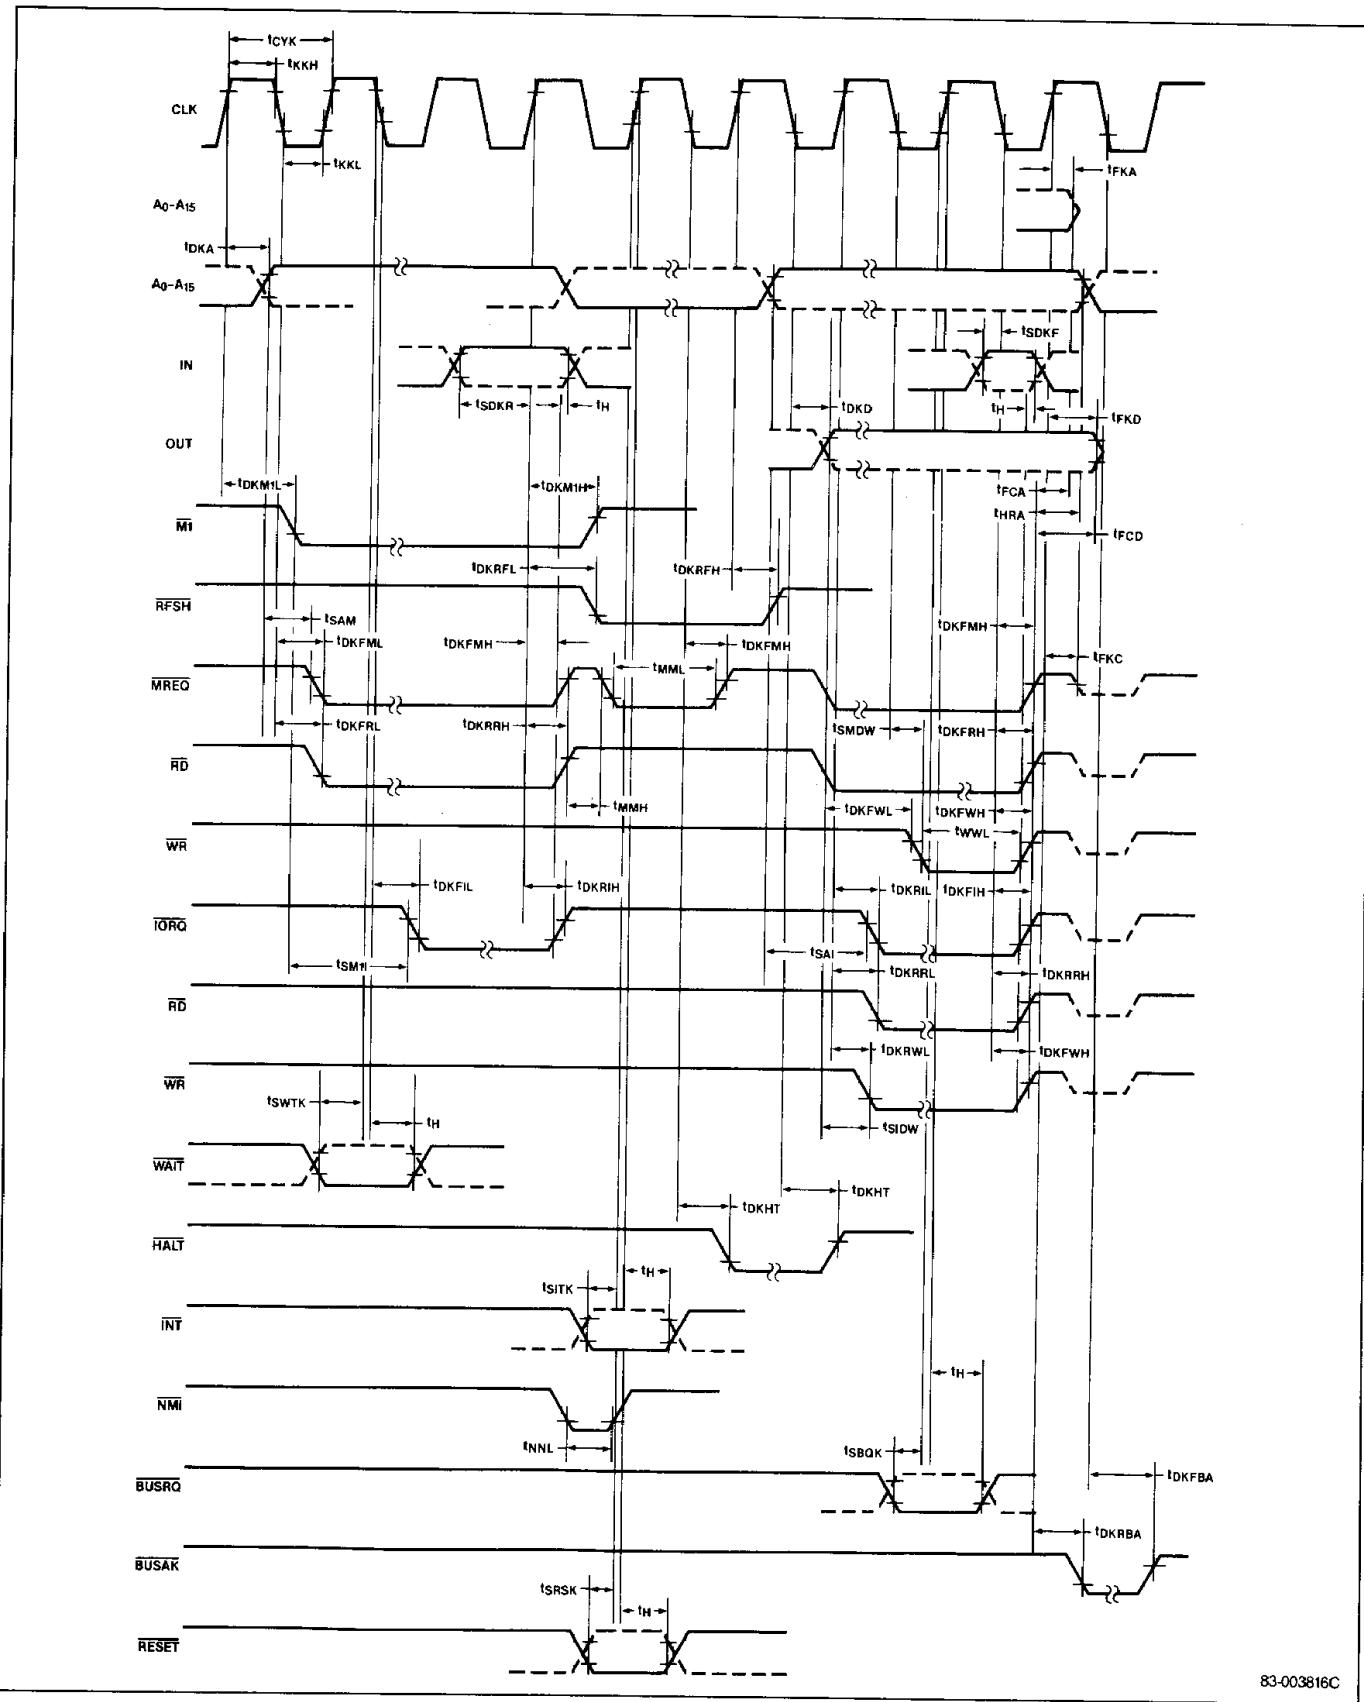

(16) $t_{MML} = t_{CYK} - 30$

(17) $t_{MMH} = t_{KKH} + t_{KF} - 20$

(18) $t_{WWL} = t_{CYK} - 30$

(19) $t_{SM1I} = 2t_{CYK} + t_{KKH} + t_{KF} - 50$

Timing Waveforms

3

Register Configuration

Program Counter (PC)

The 16-bit program counter contains the address of the next instruction to be fetched and executed. It is set to 0000H at reset.

Stack Pointer (SP)

The 16-bit stack pointer stores the first address of the portion of main memory used as a LIFO stack. SP is decremented when a CALL or PUSH is executed, or when an interrupt occurs. It is incremented when a RET, POP, or interrupt return is executed.

Index Registers (IX, IY)

These two 16-bit registers are used to perform indexed addressing.

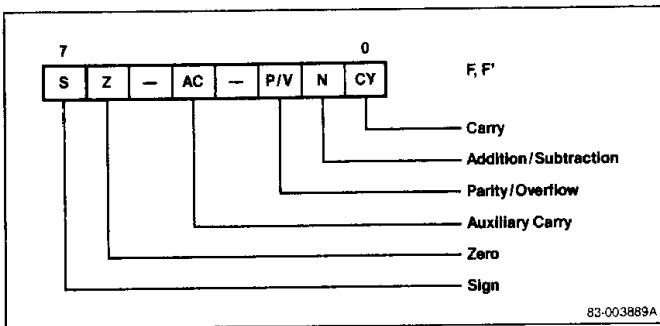

Accumulators (A, A')

The μPD70008/A has two 8-bit accumulators: the main accumulator (A) which is used to perform arithmetic and logic operations, and an alternate accumulator (A'). The contents of the main and alternate accumulators can be exchanged using the (EX) instruction. The alternate accumulator can be used for background operation, or to save the data in the main accumulator when an interrupt is processed.

Flag Registers (F, F')

The μPD70008/A has two 8-bit flag registers: main (F) and alternate (F') of the format shown in figure 1. The main flag register (F) has the status flags resulting from normal operation. The contents of the main and alternate registers can be exchanged using the exchange (EX) instruction. The alternate (F') register can be used for background operation, or to save the state of the main flag register when an interrupt is processed.

Figure 1. Flag Register Format

General Purpose Registers

The μPD70008/A has twelve 8-bit general purpose registers: six main registers (B, C, D, E, H, and L) and six alternate registers (B', C', D', E', H', and L'). Each register can be used individually as an 8-bit register, or can be used in pairs as 16-bit registers (BC, B'C', DE, D'E', HL, and H'L').

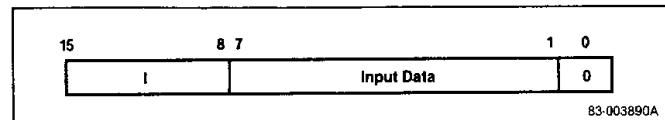

The main registers are used when instructions are executed normally. The contents of the main and alternate registers are exchanged using the EX instruction. The alternate registers may be used for background operation or to save the contents of the main registers when an interrupt is processed.

Interrupt Page Address Register (I)

This 8-bit register is used to generate addresses in maskable interrupt mode 2. See figure 2. These addresses are used with externally input data to reference an interrupt start address table.

This register is cleared to 00H at reset.

Figure 2. Interrupt Reference Address

Memory Refresh Register (R)

This 7-bit register retains the refresh address for the external dynamic memory. The contents of this register are automatically incremented in each opcode fetch (M1) cycle. The contents of this register are output on the lower 7 bits of the address bus (A₆-A₀).

This register is cleared to 00H at reset.

Timing

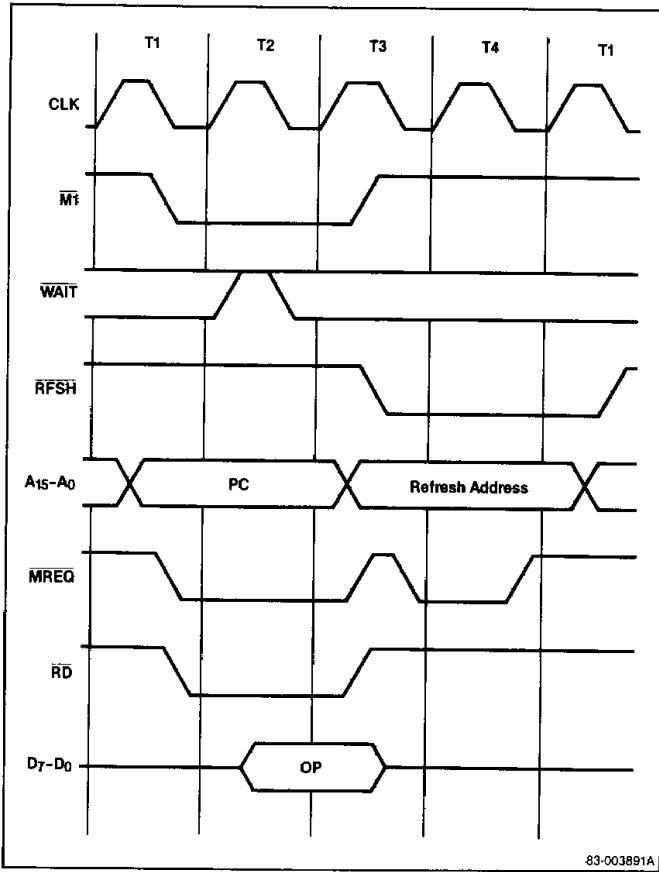

This section describes read and write timing for memory and I/O devices in connection with CPU operation timing. A single clock cycle (from one leading edge to the next) is defined as one timing state. The nth state is represented as T_n. A single instruction consists of two to six machine cycles. A single machine cycle requires three to six timing states. The nth machine cycle is represented as M_n.

Table 1 lists the number of states normally required by each cycle.

Table 1. Timing States per Cycle

Cycle	Number of States per Machine Cycle
Opcode fetch	4
Memory read	3
Memory write	3
I/O read	4
I/O write	4

The four states for I/O read and write include a single wait state (TW). The μ PD70008/A inserts one wait state in every I/O read or write. Slower external devices may assert the WAIT signal to request longer read and write access times. This time will be added to the original number of clock states. The WAIT signal is monitored on the trailing edge of clock state T2. If WAIT is asserted, a wait state (TW) is generated. The μ PD70008/A continues to monitor WAIT on the clock's trailing edge, and supplies additional wait states as long as that signal is asserted. When WAIT is released the μ PD70008/A proceeds to the T3 state.

Figure 3. Opcode Fetch Cycle

83-003891A

Opcode Fetch Cycle

The first machine cycle of each instruction, M1, is the opcode fetch cycle. See figure 3. The opcode is fetched from memory during the first half of this cycle, and the dynamic memory is refreshed during the latter half.

The memory outputs the opcode to the data bus when MREQ, RD, or M1 is asserted. It is then read into the CPU at the leading edge of clock state T3.

The CPU outputs a refresh address onto A₆-A₀ during T3. It is applied to the dynamic memory when RFSH or MREQ are asserted.

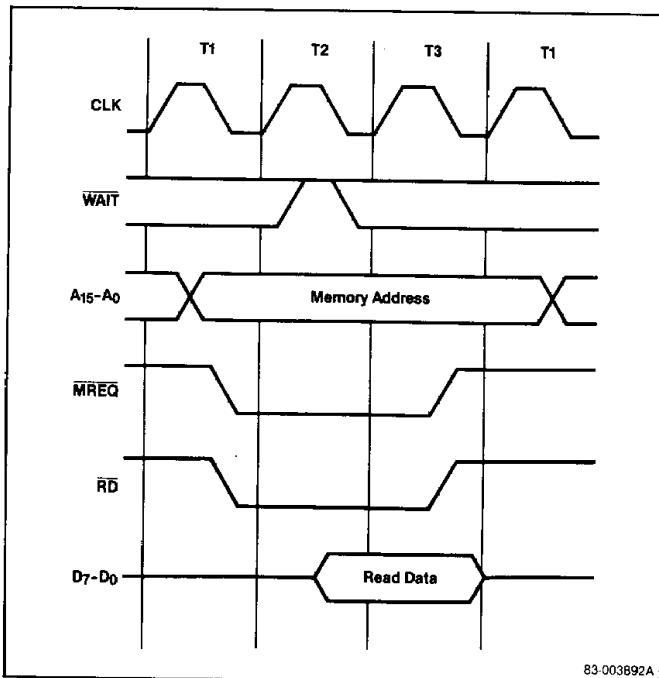

3

Memory Read Cycle

The memory contents are read out to the data bus when MREQ or RD is asserted. The μ PD70008/A reads data from the data bus on the trailing edge of T3. See figure 4.

Memory Write Cycle

Write data is output to the data bus between the last half of state T1 of the current machine cycle and the first half of state T1 of the next cycle. It is written to memory when WR or MREQ is asserted. See figure 5.

Figure 4. Memory Read Cycle

83-003892A

Figure 5. Memory Write Cycle

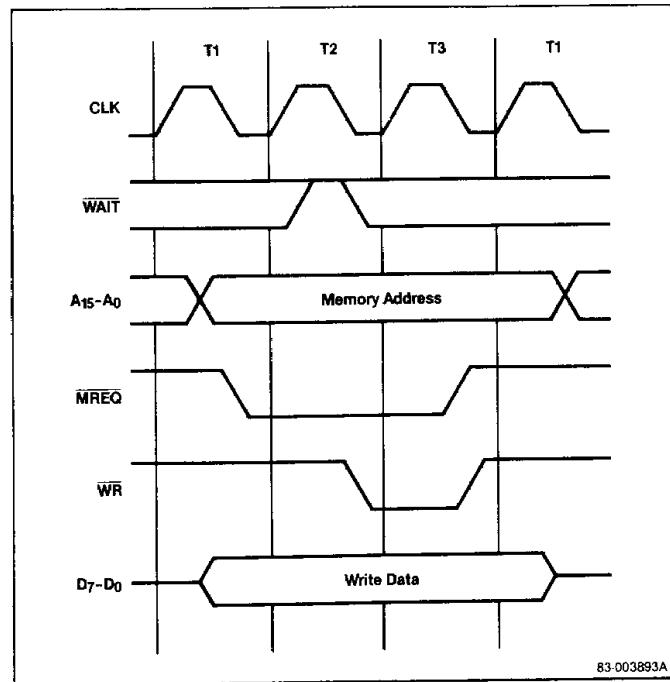

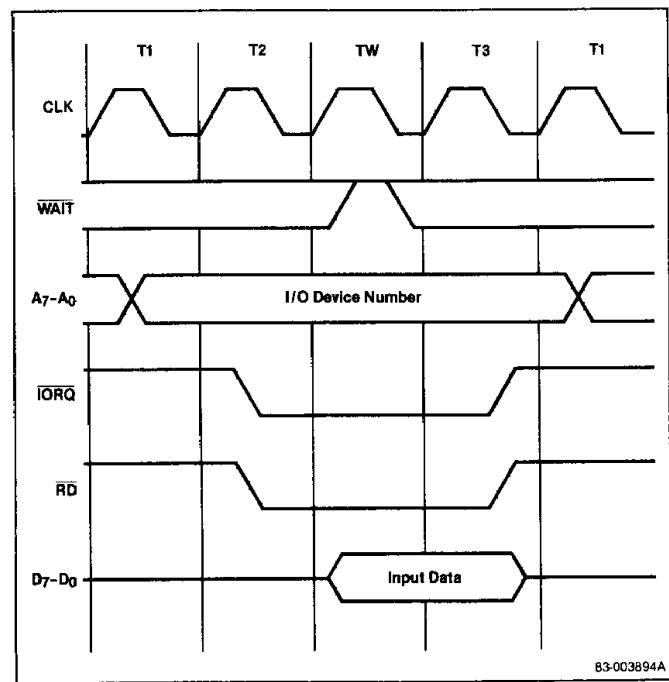

Figure 6. I/O Read Cycle

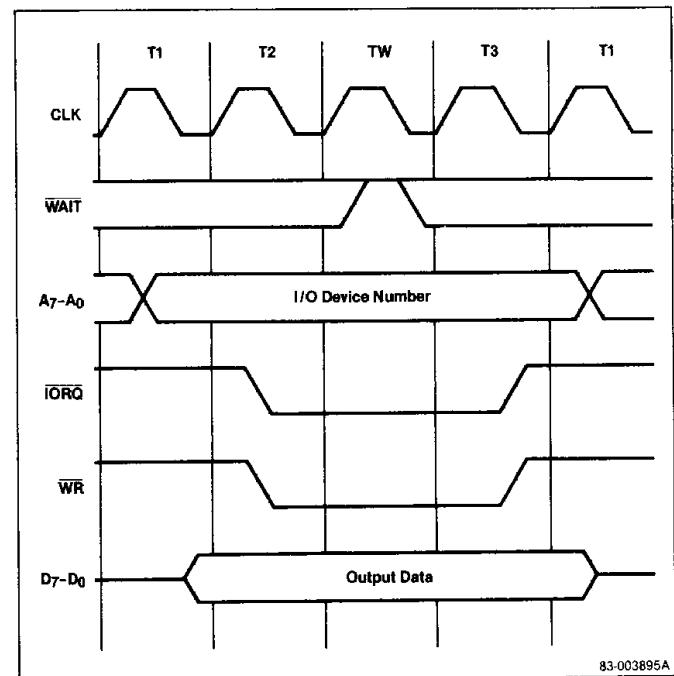

I/O Read Cycle

The contents of an I/O device are read out to the data bus when **IORQ** or **RD** is asserted. The μPD70008/A reads the data bus on the trailing edge of the T3 clock state. See figure 6. To compensate for I/O devices with longer access times, the μPD70008/A generates one wait state (TW) regardless of the condition of the **WAIT** signal. To extend the access time, the CPU must detect the **WAIT** signal asserted at the falling edge of TW.

I/O Write Cycle

Write data is output to the data bus between the last half of state T1 of the current machine cycle and the first half of T1 of the next machine cycle. It is written to an I/O device when **IORQ** or **WR** is asserted. As in the I/O read cycle, one wait state is automatically inserted in the I/O write cycle. See figure 7. The **WAIT** signal is used to insert additional wait states in the I/O write cycle in exactly the same way as in the read cycle.

Figure 7. I/O Write Cycle

Bus Request State

The bus request causes the μPD70008/A address bus ($A_{15}-A_0$), data bus (D_7-D_0), and control bus (MREQ, IORQ, RD, and WR) pins to enter the high impedance state. This makes the buses available to external devices for DMA access.

The bus request state is controlled by the bus request (BUSRQ) signal. See figure 8. The μPD70008/A detects BUSRQ at the rising edge of the last state of each machine cycle. If it is active (low) the μPD70008/A does not move on the next machine cycle, but enters the bus request state. The μPD70008/A asserts BUSAK to indicate that the BUSRQ signal has been received, and the three buses have entered the high impedance state.

BUSRQ is checked at the rising edge of all clock states. When it becomes inactive the μPD70008/A leaves the bus request state, and proceeds to the next cycle.

BUSRQ temporarily suspends the standby mode. When BUSRQ is asserted, the μPD70008/A leaves the standby mode and enters the bus request state. When BUSRQ is released the μPD70008/A returns to the standby mode.

Interrupts are disabled during the bus request state.

Interrupts

The μPD70008/A has two types of interrupt: maskable (INT) and nonmaskable (NMI). The nonmaskable interrupt request cannot be masked by software. It will be acknowledged unless the μPD70008/A is in the bus

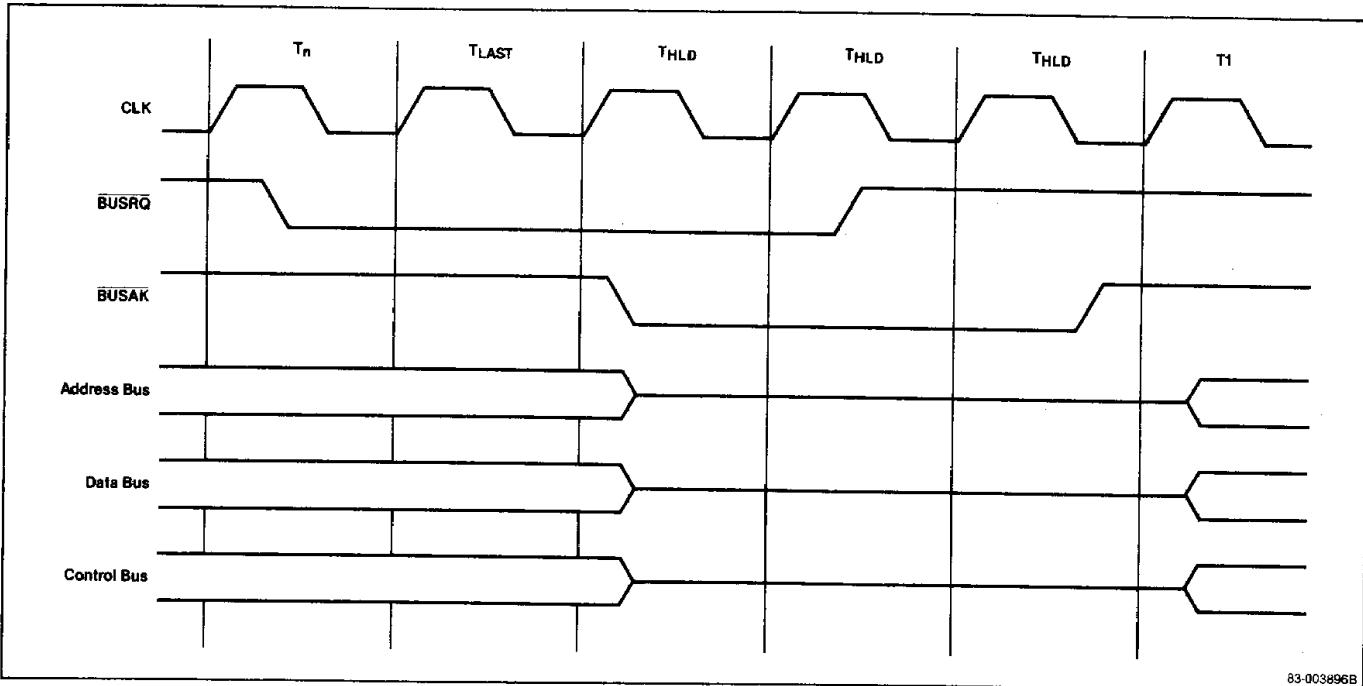

request state. The maskable interrupt can be masked by software. It is controlled by setting or resetting the interrupt enable flip-flop (IFF) using the EI or DI instructions. INT has a lower priority than the nonmaskable interrupt. The maskable interrupt will therefore not be acknowledged if there is a nonmaskable interrupt, or if the μPD70008/A is in the bus request state.

INTI < NMI < BUSRQ < RESET

Nonmaskable Interrupt Operation

The falling edge of NMI always sets the nonmaskable interrupt flip-flop. The μPD70008/A checks the flip-flop at the rising edge of the last clock state of an instruction. If it is set, the μPD70008/A transfers control to the nonmaskable interrupt service routine. The interrupt process starts at the opcode fetch cycle, (M1, 5 states) but the opcode fetched at this point is ignored. The contents of the PC are stored on the stack in the next two machine cycles (M2, 3 states and M3, 3 states). At the same time, the address 0066H is loaded into the PC, and the state of the interrupt enable flip-flop is saved to an exclusive flip-flop. The entire interrupt routine requires 3 machine cycles (11 states). The contents of the PC and IFF are restored by the execution of the RETN instruction at the end of the interrupt procedure.

Figure 8. Bus Request State

83-003896B

Maskable Interrupt Operation

Maskable interrupts are processed in three modes. In each mode, the INT signal is detected at the rising edge of the last clock state of each instruction. The M1 instruction specifies which mode is to be used.

Mode 0. In this mode, the data placed on the bus by the interrupting device is treated as an instruction. It is fetched in the opcode fetch cycle (M1, 7 states) and executed. The instruction used in this mode is usually a CALL (3 bytes) or RST (1 byte).

If a 1-byte RST instruction is executed, the contents of the PC are saved to the stack. A fixed address specified by the opcode is loaded into the PC during the next M2 (3 states) and M3 (3 states). The execution of this interrupt requires 3 machine cycles or 13 states.

If a 3-byte CALL instruction is executed, the second and third bytes are fetched during the M2 and M3 cycles (3 states each). During M4 and M5 (3 states each), the contents of the PC are saved to the stack and the second and third bytes of the CALL instruction are loaded into the PC. This interrupt requires 5 machine cycles and a total of 19 clock states.

Mode 1. In this mode, the data fetched during M1 (7 states) is ignored, and the μPD70008/A proceeds to the next cycle. During the M2 and M3 machine cycles (3 states each), the contents of the PC are saved to the stack and replaced by the interrupt address 0038H. This interrupt requires 3 machine cycles or 13 states.

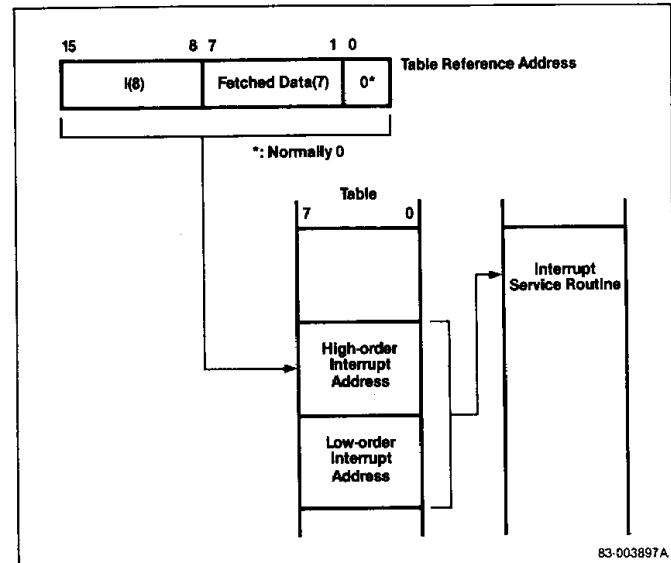

Mode 2. In this mode, the data fetched from the interrupting device and the contents of the interrupt page register (I) are used to reference an interrupt start address table. Program execution jumps to the 16-bit address referenced by the table. See figure 9. The data is fetched during the opcode fetch cycle (M1, 7 states). During M2 and M3 (3 states each) the contents of the PC are saved to the stack. During the M4 and M5 cycles, (3 states each) the table is referenced and the contents of the table location are loaded into the PC. This interrupt requires 5 machine cycles or 19 states.

Standby Mode

The μPD70008/A is provided with a standby mode (HALT). In the standby mode, power consumption is approximately 2% of normal operating power consumption. The standby mode is set by executing the HALT instruction.

In the standby mode, the state of the μPD70008/A is retained. The contents of all registers and the state of all flags are retained as well. Clock signals are supplied only to indispensable circuits in the μPD70008/A to minimize power consumption.

Figure 9. Interrupt Address Table

83-003897A

External operations such as memory access and memory refresh are not performed in the standby mode.

Table 2 shows the state of each output pin in the standby mode.

Table 2. Standby Mode

Pin	Status
Data bus	High level, pulled up through internal resistance
D ₇ -D ₀	High or low level signals
Address bus	High level (inactive)
A ₁₅ -A ₀	High level (inactive)
Control bus	RD, WR, MREQ, IORQ, M ₁
RFSH	High level (inactive)
HALT	Low level (active)

The standby mode is released when a reset or an interrupt occurs. The standby mode is temporarily suspended by a bus request, but not released.

RESET in Standby Mode

When the RESET signal becomes active (low) the standby mode is released and a normal reset is performed.

NMI in Standby Mode

When the NMI signal is asserted (low) the standby mode is released and normal nonmaskable interrupt processing is performed. The interrupt is not performed in the bus request state.

INT in Standby Mode

When the INT signal is asserted (low) the standby mode is released. If the interrupt is enabled, normal interrupt processing is performed. If the interrupt is disabled, execution resumes at the instruction following the HALT instruction.

BUSRQ in Standby Mode

The BUSRQ signal is detected at the rising edge of each clock in the standby mode. If the BUSRQ signal is active (low) the μ PD70008/A leaves the standby mode, and enters the bus request state. When BUSRQ is released, the standby mode is resumed. The standby mode is not released by the BUSRQ signal.

RESET

The RESET signal must be asserted (low) for over 3 clock cycles to be recognized. The following steps are the reset initialization process:

- The program counter (PC) is cleared to 0000H.
- The interrupt enable flip-flop (IFF) is reset to 0, disabling maskable interrupts. The interrupt mode is set to 0.
- The interrupt page address register (I) is cleared to 00H.
- The memory refresh register (R) is cleared to 00H.
- The address bus ($A_{15}-A_0$) and data bus (D_7-D_0) are set to high impedance.
- All control outputs are set in their inactive state.
- The standby mode is released.

The following registers are undefined at reset:

Stack pointer (SP)
 Accumulators (A, A')
 Flag registers (F, F')
 General purpose registers
 (B, B', C, C', D, D', E, E', H, H', L, L')
 Index registers (IX, IY)

When RESET is released the program will begin execution from location 0000H.

Instruction Set

Each operand should be written in the operand column of an instruction according to the description in table 3. Capital letters are keywords and should be written as they appear.

Table 3. Operand Description

Identifier	Description
addr	16-bit immediate data or label
faddr	00H, 08H, 10H, 18H, 20H, 28H, 30H, 38H immediate data or label
word	16-bit immediate data or label
byte	8-bit immediate data or label
bit	3-bit immediate data or label (bit specification of 8-bit register / memory)
d	8-bit displacement (signed 2's complement)
r	A, B, C, D, E, H, L
r'	A', B', C', D', E', H', L'
rp	BC, DE, HL, AF
rp1	BC, DE, HL, SP
rp2	BC, DE, IX, SP
rp3	BC, DE, IY, SP
e	Displacement for relative jump (signed 2's complement)

Selection of Register and Condition

rp	qq	rpl	ss, dd	rp2	pp	rp3	rr
BC	00	BC	00	BC	00	BC	00
DE	01	DE	01	DE	01	DE	01
HL	10	HL	10	IX	10	IY	10
AF	11	SP	11	SP	11	SP	11

r, r'	r, r'	bit	b	faddr	t
B B'	000	0	000	00H	000
C C'	001	1	001	08H	001
D D'	010	2	010	10H	010
E E'	011	3	011	18H	011
H H'	100	4	100	20H	100
L L'	101	5	101	28H	101
A A'	111	6	110	30H	110
		7	111	38H	111

Flag Operation

(Blank): Flag not affected

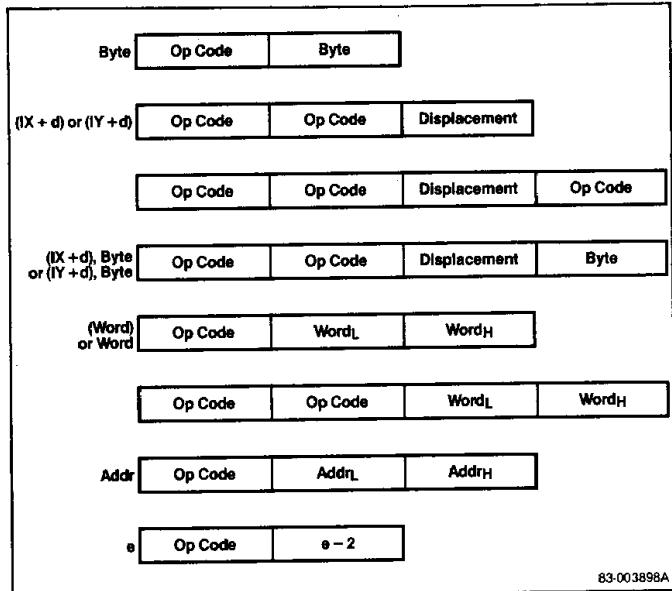

0: Flag reset

1: Flag set

X: Flag affected according to result of operation

U: Flag unknown
