

20-Bit, Stereo D/A Converter for Digital Audio

Features

- 20-Bit Conversion
- 115 dB Signal-to-Noise-Ratio (EIAJ)
- Complete Stereo DAC System
 - 128X Interpolation Filter
 - Delta-Sigma DAC
 - Analog Post Filter
- 106 dB Dynamic Range
- Low Clock Jitter Sensitivity
- Filtered Line-Level Outputs
 - Linear Phase Filtering
 - Zero Phase Error Between Channels
- Adjustable System Sampling Rates
 - including 32 kHz, 44.1 kHz & 48 kHz
- Digital De-emphasis for 32 kHz, 44.1 kHz, & 48 kHz
- Pin-compatible with the CS4390

Description

The CS4329 is a complete stereo digital-to-analog output system. In addition to the traditional D/A function, the CS4329 includes a digital interpolation filter followed by an 128X oversampled delta-sigma modulator. The modulator output controls the reference voltage input to an ultra-linear analog low-pass filter. This architecture allows for infinite adjustment of sample rate between 1 and 50 kHz while maintaining linear phase response simply by changing the master clock frequency.

The CS4329 also includes an extremely flexible serial port utilizing mode select pins to support multiple interface formats.

The master clock can be either 256, 384, or 512 times the input sample rate, supporting various audio environments.

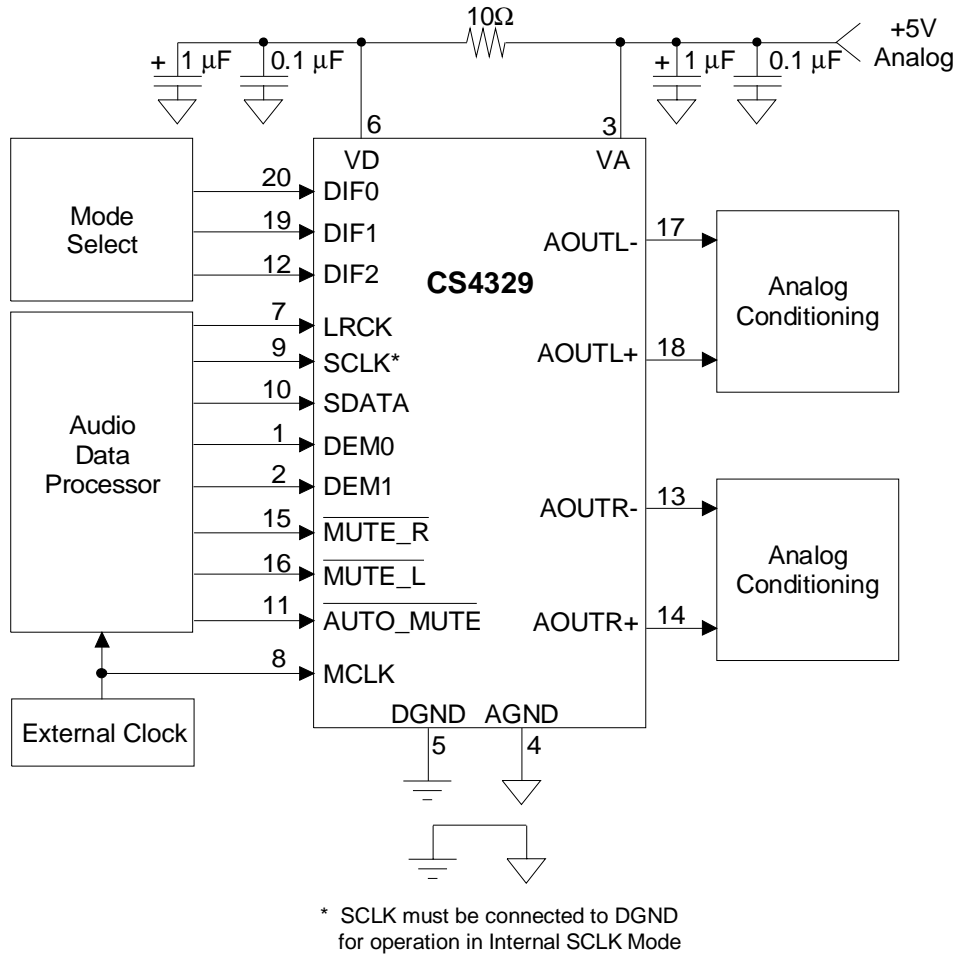

Figure 1. Typical Connection Diagram

GENERAL DESCRIPTION

The CS4329 is a complete stereo digital-to-analog system including $128\times$ digital interpolation, fourth-order delta-sigma digital-to-analog conversion, $128\times$ oversampled one-bit delta-sigma modulator and analog filtering. This architecture provides a high insensitivity to clock jitter. The DAC converts digital data at any input sample rate between 1 and 50 kHz, including the standard audio rates of 48, 44.1 and 32 kHz.

The primary purpose of using delta-sigma modulation techniques is to avoid the limitations of laser trimmed resistive DAC architectures by using an inherently linear 1-bit DAC. The advantages of a 1-bit DAC include: ideal differential linearity, no distortion mechanisms due to resistor matching errors and no linearity drift over time and temperature due to variations in resistor values.

Digital Interpolation Filter

The digital interpolation filter increases the sample rate by a factor of 4 and is followed by a $32\times$ digital sample-and hold to effectively achieve a $128\times$ interpolation filter. This filter eliminates images of the baseband audio signal which exist at multiples of the input sample rate, F_s . This allows for the selection of a less complex analog filter based on out-of-band noise attenuation requirements rather than anti-image filtering. Following the interpolation filter, the resulting frequency spectrum has images

of the input signal at multiples of $128\times$ the input sample rate. These images are removed by the external analog filter.

Delta-Sigma Modulator

The interpolation filter is followed by a fourth-order delta-sigma modulator which converts the 24-bit interpolation filter output into 1-bit data at $128\times F_s$.

Switched-Capacitor Filter

The delta-sigma modulator is followed by a digital-to-analog converter which translates the 1-bit data into a series of charge packets. The magnitude of the charge in each packet is determined by sampling of a voltage reference onto a switched capacitor, where the polarity of each packet is controlled by the 1-bit signal. This technique greatly reduces the sensitivity to clock jitter and is a major improvement over earlier generations of 1-bit digital-to-analog converters where the magnitude of charge in the D-to-A process is determined by switching a current reference for a period of time defined by the master clock.

The CS4329 incorporates a differential output to maximize the output level to minimize the amount of gain required in the output analog stage. The differential output also allows for the cancellation of common mode errors in the differential to singled-ended converter.

Figure 2. Block Diagram

SYSTEM DESIGN

Master Clock

The Master Clock, MCLK, is used to operate the digital interpolation filter and the delta-sigma modulator. MCLK must be either 256 \times , 384 \times or 512 \times the desired Input Sample Rate, Fs. Fs is the frequency at which digital audio samples for each channel are input to the DAC and is equal to the LRCK frequency. The MCLK to LRCK frequency ratio is detected automatically during the initialization sequence by counting the number of MCLK transitions during a single LRCK period. Internal dividers are then set to generate the proper clocks for the digital filter, delta-sigma modulator and switched-capacitor filter. LRCK must be synchronous with MCLK. Once the MCLK to LRCK frequency ratio has been detected, the phase and frequency relationship between the two clocks must remain fixed. If during any LRCK this relationship is changed, the CS4329 will reset. Table 1 illustrates the standard audio sample rates and the required MCLK frequencies.

Fs (kHz)	MCLK (MHz)		
	256x	384x	512x
32	8.1920	12.2880	16.3840
44.1	11.2896	16.9344	22.5792
48	12.2880	18.4320	24.5760

Table 1. Common Clock Frequencies

Serial Data Interface

The Serial Data interface is accomplished via the serial data input, SDATA, serial data clock, SCLK, and the left/right clock, LRCK. The CS4329 supports seven serial data formats which are selected via the digital input format pins DIF0, DIF1 and DIF2. The different formats control the relationship of LRCK to the serial data and the edge of SCLK used to latch the data into the input buffer. Table 2 lists the seven formats, along with the associated figure number. The serial data is represented

in 2's-complement format with the MSB-first in all seven formats.

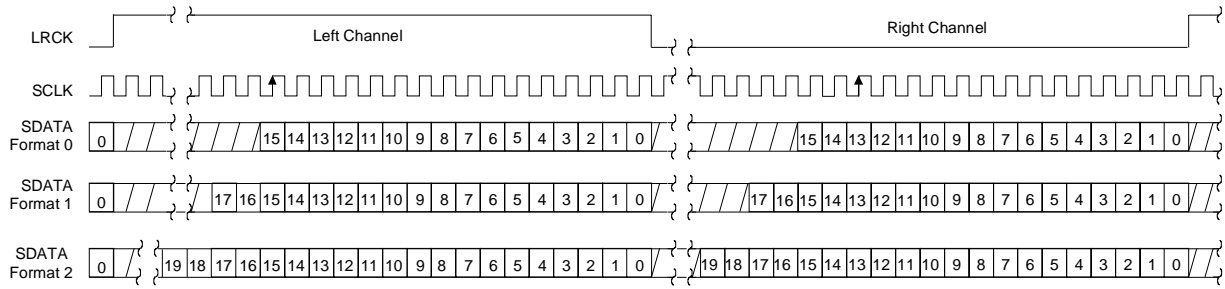

Formats 0, 1 and 2 are shown in Figure 3. The audio data is right-justified, LSB aligned with the trailing edge of LRCK, and latched into the serial input data buffer on the rising edge of SCLK. Formats 0, 1 and 2 are 16, 18 and 20-bit versions and differ only in the number of data bits required.

Formats 3 and 4 are 20-bit left justified, MSB aligned with the leading edge of LRCK, and are identical with the exception of the SCLK edge used to latch data. Data is latched on the falling edge of SCLK in Format 3 and the rising edge of SCLK in Format 4. Both formats will support 16 and 18-bit inputs if the data is followed by four or two zeros to simulate a 20-bit input as shown in Figures 4 and 5. A very small offset will result if the 18 or 16-bit data is followed by static non-zero data.

Formats 5 and 6 are compatible with the I²S serial data protocol and are shown in Figures 6 and 7. Notice that the MSB is delayed 1 period of SCLK following the leading edge of LRCK and LRCK is inverted compared to the previous formats. Data is latched on the rising edge of SCLK. Format 5 is 16-bit I²S while Format 6 is 20-bit I²S. 18-bit I²S can be implemented in Format 6 if the data is followed by two zeros to simulate a 20-bit input as shown in Figure 7. A very small offset will result if the 18-bit data is followed by static non-zero data.

DIF2	DIF1	DIF0	Format	Figure
0	0	0	0	3
0	0	1	1	3

Serial Clock

The serial clock controls the shifting of data into the input data buffers. The CS4329 supports both external and internal serial clock generation modes.

External Serial Clock

The CS4329 will enter the external serial clock mode if 15 or more high\low transitions are detected on the SCLK pin during any phase of the LRCK period. When this mode is enabled, internal serial clock mode cannot be accessed without returning to the power down mode.

Internal Serial Clock

In the Internal Serial Clock Mode, the serial clock is internally derived and synchronous with MCLK. The internal SCLK / LRCK ratio is always 64 and operation in this mode is identical to operation with an external serial clock synchronized with LRCK. The SCLK pin must be connected to DGND for proper operation.

The internal serial clock mode is advantageous in that there are situations where improper serial clock routing on the printed circuit board can degrade system performance. The use of the internal serial clock mode simplifies the routing of the printed circuit board by allowing the serial clock trace to be deleted and avoids possible interference effects.

Mute Functions

The CS4329 includes an auto-mute function which will initiate a mute if 8192 consecutive 0's or 1's are input on both the Left and Right channels. The mute will be released when non-static input data is applied to the DAC. The auto-mute function is useful for applications, such as compact disk players, where the idle channel noise must be minimized. This feature is active only if the $\overline{\text{AUTO_MUTE}}$ pin is low and is independent of the status of MUTE_L and MUTE_R. Either channel can also be muted instantaneously with the MUTE_L or MUTE_R.

De-Emphasis

Implementation of digital de-emphasis requires re-configuration of the digital filter to maintain the filter response shown in Figure 8 at multiple sample rates. The CS4329 is capable of digital de-emphasis for 32, 44.1 or 48kHz sample rates. Table 3 shows the de-emphasis control inputs for DEM 0 and DEM 1.

DEM 1	DEM 0	De-emphasis
0	0	32 kHz
0	1	44.1 kHz
1	0	48 kHz
1	1	OFF

Table 3. De-Emphasis Filter Selection

Figure 8. De-emphasis Filter Response

Initialization, Calibration and Power-Down

Upon initial power-up, the DAC enters the power-down mode. The interpolation filters and delta-sigma modulators are reset, and the internal voltage reference, one-bit D/A converters and switched-capacitor low-pass filters are powered down. The device will remain in the power-down mode until MCLK and LRCK are presented. Once MCLK and LRCK are detected, MCLK occurrences are counted over one LRCK period to determine the MCLK/LRCK frequency ratio. The phase and frequency relationship between the two clocks must remain fixed. If during any LRCK this relationship

is changed, the CS4390 will reset. Power is applied to the internal voltage reference, the D/A converters, switched-capacitor filters and the DAC will then enter a calibration mode to properly set the common mode bias voltage and minimize the differential offset. This initialization and calibration sequence requires approximately 2700 cycles of LRCK.

A offset calibration can also be invoked by taking the Format select pins, DIF0, DIF1 and DIF2, to a logic 1 as shown in Table 2. During calibration, the differential outputs are shorted together and the common-mode voltage appears at the output with approximately an 8 kohm output impedance. Following calibration, the analog output impedance becomes less than 10 ohms and the common mode voltage will move to approximately 2.2 V .

The CS4329 will enter the power-down mode, within 1 period of LRCK, if either MCLK or LRCK is removed. The initialization sequence, as described above, occurs when MCLK and LRCK are restored.

Combined Digital and Analog Filter Response

The frequency response of the combined analog switched-capacitor and digital filters is shown in Figures 9, 10 and 11. The overall response is clock dependent and will scale with Fs. Note that the response plots have been normalized to Fs and can be de-normalized by multiplying the X-axis scale by Fs, such as 48 kHz.

Analog Output and Filtering

The analog output should be operated in a differential mode which allows for the cancellation of common mode errors including noise, distortion and offset voltage. Each output will produce a nominal 2.83 Vpp (1 Vrms) output for a full scale digital input which equates to a 5.66 Vpp (2Vrms) differential signal as shown in Figure 12.

Figure 9. CS4329 Combined Digital and Analog Filter Stopband Rejection

Figure 10. CS4329 Combined Digital and Analog Filter

Figure 11. Combined Digital and Analog Filter

Figure 13 displays the CS4329 output noise spectrum. The noise beyond the audio band can be further reduced with additional analog filtering. The applications note "Design Notes for a 2-Pole Filter with Differential Input " discusses the second-order Butterworth filter and differential to signal-ended converter which was implemented on the CS4329 evaluation board, CDB4329. The CS4329 filter is a linear phase design and does not include phase or amplitude compensation for an external filter. Therefore, the DAC system phase and amplitude response will be dependent on the external analog circuitry.

Figure 12. Full Scale Input Voltage

Figure 13. CS4329 Output Noise Spectrum

Grounding and Power Supply Decoupling

As with any high resolution converter, the CS4329 requires careful attention to power supply and grounding arrangements to optimize performance.

Figure 1 shows the recommended power arrangements with VA connected to a clean +5volt supply. VD should be derived from VA through a 10 Ω resistor. VD should not be used to power additional digital circuitry. All mode pins which require VD should be connected to pin 6 of the CS4329. All mode pins which require DGND should be connected to pin 5 of the CS4329. Pins 4 and 5, AGND and DGND, should be connected together at the CS4329. DGND for the CS4329 should not be confused with the ground for the digital section of the system. The CS4329 should be positioned over the analog ground plane near the digital/analog ground plane split. The analog and digital ground planes must be connected elsewhere in the system. The CS4329 evaluation board, CDB4329, demonstrates this layout technique. This technique minimizes digital noise and insures proper power supply matching and sequencing. Decoupling capacitors should be located as near to the CS4329 as possible.

Performance Plots

The following collection of CS4329 measurement plots were taken from the CDB4329 evaluation board using the Audio Precision Dual Domain System Two.

Figure 14 shows the frequency response at a 48 kHz sample rate. The response is flat to 20 kHz +/-0.1 dB as specified.

Figure 15 shows THD+N versus signal amplitude for a 1 kHz 20-bit dithered input signal. Notice that the there is no increase in distortion as the signal level decreases. This indicates very good low-level linearity, one of the key benefits of delta-sigma digital to analog conversion.

Figure 16 shows a 16 k FFT of a 1 kHz full-scale input signal. The signal has been filtered by a notch filter within the System Two to remove the fundamental component of the signal. This minimizes the distortion created in the analyzer analog-to-digital converter. This technique is discussed by Audio

Precision in the 10th anniversary addition of AUDIO.TST.

Figure 17 shows a 16 k FFT of a 1 kHz -20 dBFS input signal. The signal has been filtered by a notch filter within the System Two to remove the fundamental component of the signal.

Figure 18 shows a 16 k FFT of a 1 kHz -60 dBFS input signal.

Figure 19 shows the fade-to-noise linearity. The input signal is a dithered 20-bit 500 Hz sine wave which fades from -60 to -120 dBFS. During the fade, the output from the CS4329 is measured and compared to the ideal level. Notice the very close tracking of the output level to the ideal, even at low

level inputs. The gradual shift of the plot away from zero at signals levels < -110 dB is caused by the background noise starting to dominate the measurement.

PIN DESCRIPTIONS
PDIP and SSOP

Power Supply Connections
VA - Positive Analog Power, PIN 3.

Positive analog supply. Nominally +5 volts.

VD - Positive Digital Power, PIN 6.

Positive supply for the digital section. Nominally +5 volts.

AGND - Analog Ground, PIN 4.

Analog ground reference.

DGND - Digital Ground, PIN 5.

Digital ground for the digital section.

Analog Outputs
AOUTR+,AOUTR- - Differential Right Channel Analog Outputs, PIN 14, PIN 13.

Analog output connections for the Right channel differential outputs. Nominally 2 Vrms (differential) for full-scale digital input signal.

AOUTL+,AOUTL- - Differential Left Channel Analog Outputs, PIN 18, PIN 17.

Analog output connections for the Left channel differential outputs. Nominally 2 Vrms (differential) for full-scale digital input signal.

Digital Inputs

MCLK - Clock Input, PIN 8.

The frequency must be either 256×, 384× or 512× the input sample rate (Fs).

LRCK - Left/Right Clock, PIN 7.

This input determines which channel is currently being input on the Serial Data Input pin, SDATA. The format of LRCK is controlled by DIF0, DIF1 and DIF2.

SCLK - Serial Bit Input Clock, PIN 9.

Clocks the individual bits of the serial data in from the SDATA pin. The edge used to latch SDATA is controlled by DIF0, DIF1 and DIF2.

SDATA - Serial Data Input, PIN 10.

Two's complement MSB-first serial data of either 16, 18 or 20 bits is input on this pin. The data is clocked into the CS4329 via the SCLK clock and the channel is determined by the LRCK clock. The format for the previous two clocks is determined by the Digital Input Format pins, DIF0, DIF1 and DIF2.

DIF0, DIF1, DIF2 - Digital Input Format, PINS 20, 19, 12

These three pins select one of seven formats for the incoming serial data stream. These pins set the format of the SCLK and LRCK clocks with respect to SDATA. The formats are listed in Table 2.

DEM0, DEM1 - De-Emphasis Select, PINS 1, 2.

Controls the activation of the standard 50/15us de-emphasis filter for either 32, 44.1 or 48 kHz sample rates.

AUTO-MUTE - Automatic Mute on Zero-Data, PIN 11.

When Auto-Mute is low the analog outputs are muted following 8192 consecutive LRCK cycles of static 0 or 1 data. Mute is canceled with the return of non-static input data.

MUTE_R , MUTE_L Mute, PINS 15, 16.

MUTE_L low activates a muting function for the Left channel. MUTE_R low activates a muting function for the Right channel.

PARAMETER DEFINITIONS

Dynamic Range

The ratio of the full scale rms value of the signal to the rms sum of all other spectral components over the specified bandwidth. Dynamic range is a signal-to-noise measurement over the specified bandwidth made with a -60 dBFS signal. 60 dB is then added to the resulting measurement to refer the measurement to full scale. This technique ensures that the distortion components are below the noise level and do not effect the measurement. This measurement technique has been accepted by the Audio Engineering Society, AES17-1991, and the Electronic Industries Association of Japan, EIAJ CP-307.

Total Harmonic Distortion + Noise

The ratio of the rms value of the signal to the rms sum of all other spectral components over the specified bandwidth (typically 10 Hz to 20 kHz), including distortion components. Expressed in decibels.

Idle Channel Noise / Signal-to-Noise-Ratio

The ratio of the rms analog output level with 1kHz full scale digital input to the rms analog output level with all zeros into the digital input. Measured A-weighted over a 10 Hz to 20 kHz bandwidth. Units in decibels. This specification has been standardized by the Audio Engineering Society, AES17-1991, and referred to as Idle Channel Noise. This specification has also been standardized by the Electronic Industries Association of Japan, EIAJ CP-307, and referred to as Signal-to-Noise-Ratio.

Interchannel Isolation

A measure of crosstalk between the left and right channels. Measured for each channel at the converter's output with all zeros to the input under test and a full-scale signal applied to the other channel. Units in decibels.

Frequency Response

A measure of the amplitude response variation from 10 Hz to 20 kHz relative to the amplitude response at 1 kHz. Units in decibels.

De-Emphasis Error

A measure of the difference between the ideal de-emphasis filter and the actual de-emphasis filter response. Measured from 10 Hz to 20 kHz relative to 1 kHz. Units in decibels.

Interchannel Gain Mismatch

The gain difference between left and right channels. Units in decibels.

Gain Error

The deviation from the nominal full scale analog output for a full scale digital input.

Gain Drift

The change in gain value with temperature. Units in ppm/°C.

- Notes:
1. "D" and "E1" are reference datums and do not include mold flash or protrusions, but do include mold mismatch and are measured at the parting line, mold flash or protrusions shall not exceed 0.20 mm per side.
 2. Dimension "b" does not include dambar protrusion/intrusion. Allowable dambar protrusion shall be 0.13 mm total in excess of "b" dimension at maximum material condition. Dambar intrusion shall not reduce dimension "b" by more than 0.07 mm at least material condition.
 3. These dimensions apply to the flat section of the lead between 0.10 and 0.25 mm from lead tips.

Evaluation Board for CS4329 and CS4390

Features

- Demonstrates recommended layout and grounding arrangements
- CS8412 Receives AES/EBU, S/PDIF, & EIAJ-340 Compatible Digital Audio
- Digital and Analog Patch Areas
- Requires only a digital signal source and power supplies for a complete Digital-to-Analog-Converter system

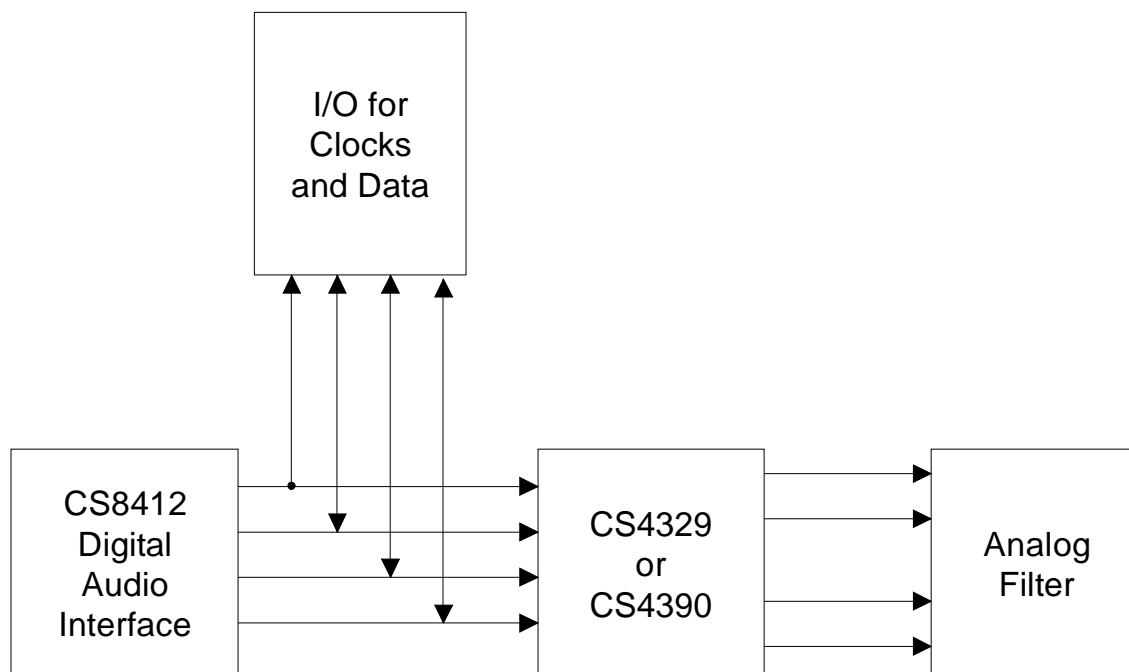

Description

The CDB4329/90 evaluation board is an excellent means for quickly evaluating the CS4329 or CS4390 24-bit, stereo D/A converter. Evaluation requires an analog signal analyzer, a digital signal source and a power supply. Analog outputs are provided via RCA connectors for both channels.

The CS8412 digital audio receiver I.C. provides the system timing necessary to operate the CS4329/90 and will accept AES/EBU, S/PDIF, and EIAJ-340 compatible audio data. The evaluation board may also be configured to accept external timing signals for operation in a user application during system development.

Preliminary Product Information

This document contains information for a new product. Cirrus Logic reserves the right to modify this product without notice.

CDB4329/90 SYSTEM OVERVIEW

The CDB4329/90 evaluation board is an excellent means of quickly evaluating the CS4329/90. The CS8412 digital audio interface receiver provides an easy interface to digital audio signal sources including the majority of digital audio test equipment. The evaluation board also allows the user to supply clocks and data through a 10-pin header for system development.

The CDB4329/90 schematic has been partitioned into 8 schematics shown in Figures 2 through 9. Each partitioned schematic is represented in the system diagram shown in Figure 1. Notice that the system diagram also includes the interconnections between the partitioned schematics.

CS4329/90 Digital to Analog Converter

A description of the CS4329 or CS4390 is included in the CS4329 and CS4390 data sheets.

CS8412 Digital Audio Receiver

The system receives and decodes the standard S/PDIF data format using a CS8412 Digital Audio Receiver, Figure 9. The outputs of the CS8412 include a serial bit clock, serial data, left-right clock (FSYNC), de-emphasis control and a 256Fs master clock.

During normal operation, the CS8412 operates in the Channel Status mode where the LED's display channel status information for the channel selected by the CSLR/FCK jumper. This allows the CS8412 to decode and supply the de-emphasis bit from the digital audio interface for control of the CS4329/90 de-emphasis filter via pin 3, CC/F0, of the CS8412.

When the Error Information Switch is activated, the CS8412 operates in the Error and Frequency information mode. The information displayed by the LED's can be decoded by consulting the CS8412 data sheet. If the Error Information Switch is activated, the CC/F0 output has no relation to the de-emphasis bit and it is likely that the de-emphasis

control for the CS4329/90 will be erroneous and produce an incorrect audio output.

Encoded sample frequency information can be displayed provided a proper clock is being applied to the FCK pin of the CS8412. When an LED is lit, this indicates a "1" on the corresponding pin located on the CS8412. When an LED is off, this indicates a "0" on the corresponding pin. Neither the L or R option of CSLR/FCK should be selected if the FCK pin is being driven by a clock signal.

The evaluation board has been designed such that the input can be either optical or coax, Figure 8. It is not necessary to select the active input. However, both inputs can not be driven simultaneously.

Data Format

The CS4329/90 must be configured to be compatible with the incoming data and can be set with DIF0, DIF1, and DIF2. The CS8412 data format can be set with the M0, M1, M2 and M3. There are several data formats which the CS8412 can produce that are compatible with CS4329/90. Refer to Table 2 for one possibility.

Power Supply Circuitry

Power is supplied to the evaluation board by four binding posts, Figure 10. The +5 Volt input supplies power to the CS4329/90 (through VA+), the CS8412 (through VA+ and VD+), and the +5 Volt digital circuitry (through VD+). The ±12 volt input supplies power to the analog filter circuitry.

Input/Output for Clocks and Data

The evaluation board has been designed to allow the interface to external systems via the 10-pin header, J1. This header allows the evaluation board to accept externally generated clocks and data. The schematic for the clock/data I/O is shown in Figure 7. The 74HC243 transceiver functions as an I/O buffer where the CLK SOURCE jumper determines if the transceiver operates as a transmitter or receiver.

The transceiver operates as a transmitter with the CLK SOURCE jumper in the 8412 position. LRCK, SDATA, and SCLK from the CS8412 will be available on J1. J22 must be in the 0 position and J23 must be in the 1 position for MCLK to be an output and to avoid bus contention on MCLK.

The transceiver operates as a receiver with the CLK SOURCE jumper in the EXTERNAL position. LRCK, SDATA and SCLK on J1 become inputs. The CS8412 must be removed from the evaluation board for operation in this mode.

There are 2 options for the source of MCLK in the EXT CLK source mode. MCLK can be an input with J23 in the 1 position and J22 in the 0 position. However, the recommended mode of operation is to generate MCLK on the evaluation board. MCLK becomes an output with LRCK, SCLK and SDATA inputs. This technique insures that the CS4329/90 receives a jitter free clock to maximize performance. This can be accomplished by installing a crystal oscillator into U4, see Figure 9 (the socket for U4 is located within the footprint for the CS8412) and placing J22 in the 1 position and J23 in the 0 position.

Analog Filter

The design of the second-order Butterworth low-pass filter, Figure 6, is discussed in the CS4329 and CS4390 data sheets and the applications note "Design Notes for a 2-pole Filter with Differential Input."

Grounding and Power Supply Decoupling

The CS4329/90 requires careful attention to power supply and grounding arrangements to optimize performance. The recommended power arrangements would be VA+ connected to a clean +5 Volt supply. The voltage VD+ (pin 6 of the CS4329/90) should be derived from VA+ through a 2 ohm resistor and should not be used for any additional digital circuitry. Ideally, mode pins which require this voltage should be connected directly to VD+ (pin 6 of the CS4329/90) and mode pins which require DGND should be connected directly to pin 5 of the CS4329/90. AGND and DGND, Pins 4 and 5, are connected together at the CS4329/90. However, it was not possible to connect VD+ (pin 6 of the CS4329/90) and DGND to the mode pins on the CDB4329/90 due to layout complications resulting from the hardware selected to exercise the features of the CS4329/90.

Figure 2 shows the CS4329/90 and connections. The evaluation board has separate analog and digital regions with individual ground planes. DGND for the CS4329/90 should not be confused with the ground for the digital section of the system (GND). The CS4329/90 is positioned over the analog ground plane near the digital/analog ground plane split. These ground planes are connected elsewhere on the board. This layout technique is used to minimize digital noise and to insure proper power supply matching/sequencing. The decoupling capacitors are located as close to the CS4329/90 as possible. Extensive use of ground plane fill on both the analog and digital sections of the evaluation board yield large reductions in radiated noise effects.

CONNECTOR	INPUT/OUTPUT	SIGNAL PRESENT
+5V	input	+5 Volts for the CS4329/90, CS8412 and digital section
±12V	input	±12 volts for analog filter section
GND	input	ground connection from power supply
Digital input	input	digital audio interface input via coax
Optical input	input	digital audio interface input via optical
J1	input/output	I/O for system clocks and digital audio data
AOUTL	output	left channel analog output
AOUTR	output	right channel analog output
