

NPN Silicon Power Darlington High Voltage Autoprotected

The BU323Z is a planar, monolithic, high-voltage power Darlington with a built-in active zener clamping circuit. This device is specifically designed for unclamped, inductive applications such as Electronic Ignition, Switching Regulators and Motor Control, and exhibit the following main features:

- Integrated High-Voltage Active Clamp
- Tight Clamping Voltage Window (350 V to 450 V) Guaranteed Over the -40°C to $+125^{\circ}\text{C}$ Temperature Range
- Clamping Energy Capability 100% Tested in a Live Ignition Circuit
- High DC Current Gain/Low Saturation Voltages Specified Over Full Temperature Range
- Design Guarantees Operation in SOA at All Times
- Offered in Plastic SOT-93/TO-218 Type or TO-220 Packages
- **This device is available in Pb-free package(s). Specifications herein apply to both standard and Pb-free devices. Please see our website at www.onsemi.com for specific Pb-free orderable part numbers, or contact your local ON Semiconductor sales office or representative.**

BU323Z

Figure 1. $I_C = f(V_{CE})$ Curve Shape

By design, the BU323Z has a built-in avalanche diode and a special high voltage driving circuit. During an auto-protect cycle, the transistor is turned on again as soon as a voltage, determined by the zener threshold and the network, is reached. This prevents the transistor from going into a Reverse Bias Operating limit condition. Therefore, the device will have an extended safe operating area and will always appear to be in "FBSOA." Because of the built-in zener and associated network, the $I_C = f(V_{CE})$ curve exhibits an unfamiliar shape compared to standard products as shown in Figure 1.

Figure 2. Basic Energy Test Circuit

The bias parameters, V_{CLAMP} , I_{B1} , $V_{BE(off)}$, I_{B2} , I_C , and the inductance, are applied according to the Device Under Test (DUT) specifications. V_{CE} and I_C are monitored by the test system while making sure the load line remains within the limits as described in Figure 4.

Note: All BU323Z ignition devices are 100% energy tested, per the test circuit and criteria described in Figures 2 and 4, to the minimum guaranteed repetitive energy, as specified in the device parameter section. The device can sustain this energy on a repetitive basis without degrading any of the specified electrical characteristics of the devices. The units under test are kept functional during the complete test sequence for the test conditions described:

$I_{C(peak)} = 7.0 \text{ A}$, $I_{CH} = 5.0 \text{ A}$, $I_{CL} = 100 \text{ mA}$, $I_B = 100 \text{ mA}$, $R_{BE} = 100 \Omega$, $V_{gate} = 280 \text{ V}$, $L = 8.0 \text{ mH}$

Figure 3. Forward Bias Safe Operating Area

The shaded area represents the amount of energy the device can sustain, under given DC biases ($I_C/I_B/V_{BE(off)}/R_{BE}$), without an external clamp; see the test schematic diagram, Figure 2.

The transistor **PASSES** the Energy test if, for the inductive load and $I_{CPEAK}/I_B/V_{BE(off)}$ biases, the V_{CE} remains outside the shaded area and greater than the V_{GATE} minimum limit, Figure 4a.

The transistor **FAILS** if the V_{CE} is less than the V_{GATE} (minimum limit) at any point along the V_{CE}/I_C curve as shown on Figures 4b, and 4c. This assures that hot spots and uncontrolled avalanche are not being generated in the die, and the transistor is not damaged, thus enabling the sustained energy level required.

The transistor **FAILS** if its Collector/Emitter breakdown voltage is less than the V_{GATE} value, Figure 4d.
