This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit.

This CMOS memory circuit has been designed to meet the dc and ac specifications shown in the tables, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow of at least 500 linear feet per minute is maintained.

1.  $\overline{W}$  is high for read cycle.
2.  $\overline{E1}$  and E2 are represented by  $\overline{E}$  in this data sheet. E2 is of opposite polarity to  $\overline{E}$ .
3. All timings are referenced from the last valid address to the first transitioning address.
4. Addresses valid prior to or coincident with  $\overline{E}$  going low.
5. At any given voltage and temperature, t<sub>EHQZ</sub> (max) is less than t<sub>ELQX</sub> (min), and t<sub>GHQZ</sub> (max) is less than t<sub>GLQX</sub> (min), both for a given device and from device to device.
6. Transition is measured ± 500 mV from steady-state voltage with load of Figure 1B.
7. This parameter is sampled and not 100% tested.
8. Device is continuously selected ( $\overline{E1} = V_{IL}$ , E2 = V<sub>IH</sub>,  $\overline{G} = V_{IL}$ ).

**TIMING LIMITS**

The table of timing values shows either a minimum or a maximum limit for each parameter. Input requirements are specified from the external system point of view. Thus, address setup time is shown as a minimum since the system must supply at least that much time (even though most devices do not require it). On the other hand, responses from the memory are specified from the device point of view. Thus, the access time is shown as a maximum since the device never provides data later than that time.
