FEATURES
Two 12-Bit DACs in One Package
DAC Ladder Resistance Matching: $0.5 \%$
Surface-Mount Package
4-Quadrant Multiplication
Low Gain Error (3 LSB max Over Temperature)
Byte Loading Structure
Fast Interface Timing
APPLICATIONS
Automatic Test Equipment
Programmable Filters
Audio Applications
Synchro Applications
Process Control

## GENERAL DESCRIPTION

The AD7937 contains two 12-bit current output DACs on one monolithic chip. A separate reference input is provided for each DAC. The dual DAC saves valuable board space, and the monolithic construction ensures excellent thermal tracking. Both DACs are guaranteed 12 -bit monotonic over the full temperature range.
The AD7937 has a 2-byte (eight LSBs, four MSBs) loading structure. It is designed for right-justified data format. The control signals for register loading are A0, A1, $\overline{\mathrm{CS}}, \overline{\mathrm{WR}}$, and $\overline{\mathrm{UPD}}$. Data is loaded to the input registers when $\overline{\mathrm{CS}}$ and $\overline{\mathrm{WR}}$ are low. To transfer this data to the DAC registers, $\overline{\text { UPD }}$ must be taken low with $\overline{\mathrm{WR}}$.
Added features on the AD7937 include an asynchronous $\overline{\text { CLR }}$ line which is very useful in calibration routines. When this is taken low, all registers are cleared. The double buffering of the data inputs allows simultaneous update of both DACs. Also, each DAC has a separate AGND line. This increases the device versatility; for instance, one DAC may be operated with AGND biased while the other is connected in the standard configuration.
The AD7937 is manufactured using the Linear Compatible CMOS (LC ${ }^{2}$ MOS) process. It is speed compatible with most microprocessors and accepts TTL, 74 HC , and 5 V CMOS logic level inputs.

## FUNCTIONAL BLOCK DIAGRAM

## PRODUCT HIGHLIGHTS

1. DAC-to-DAC Matching

Since both DACs are fabricated on the same chip, precise matching and tracking is inherent. Many applications that are not practical using two discrete DACs are now possible.
Typical matching: $0.5 \%$.
2. Small Package Size

The AD7937 is packaged in a small 24 -lead SOIC.
3. Wide Power Supply Tolerance

The device operates on a $5 \mathrm{~V}_{\mathrm{DD}}$, with $\pm 10 \%$ tolerance on this nominal figure. All specifications are guaranteed over this range.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7937 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN FUNCTION DESCRIPTIONS

| 24 | AGNDB | Analog Ground for DAC B. |

## PIN CONFIGURATION

 SOIC

## CIRCUIT INFORMATION - D/A SECTION

The AD7937 contains two identical 12-bit multiplying D/A converters. Each DAC consists of a highly stable R-2R ladder and 12 N -channel current steering switches. Figure 2 shows a simplified D/A circuit for DAC A. In the R-2R ladder, binary weighted currents are steered between $\mathrm{I}_{\mathrm{OUTA}}$ and AGNDA. The current flowing in each ladder leg is constant, irrespective of switch state. The feedback resistor $\mathrm{R}_{\text {FBA }}$ is used with an op amp (see Figures 4 and 5) to convert the current flowing in $\mathrm{I}_{\text {OUTA }}$ to a voltage output.

Figure 2. Simplified Circuit Diagram for DAC A

## EQUIVALENT CIRCUIT ANALYSIS

Figure 3 shows the equivalent circuit for one of the D/A converters (DAC A) in the AD7937. A similar equivalent circuit can be drawn for DAC B.

Figure 3. Equivalent Analog Circuit for DAC A
$\mathrm{C}_{\text {OUt }}$ is the output capacitance due to the N -channel switches and varies from about 50 pF to 100 pF with digital input code. The current source $I_{\text {LKG }}$ is composed of surface and junction leakages and approximately doubles every $10^{\circ} \mathrm{C} . \mathrm{R}_{\mathrm{O}}$ is the equivalent output resistance of the device which varies with input code.

## DIGITAL CIRCUIT INFORMATION

The digital inputs are designed to be both TTL and 5 V CMOS compatible. All logic inputs are static protected MOS gates with typical input currents of less than 1 nA .

## UNIPOLAR BINARY OPERATION

## (2-QUADRANT MULTIPLICATION)

Figure 4 shows the circuit diagram for unipolar binary operation. With an ac input, the circuit performs 2-quadrant multiplication. The code table for Figure 4 is given in Table II.
Operational amplifiers A1 and A2 can be in a single package (AD644, AD712) or separate packages (AD544, AD711, AD OP27). Capacitors C1 and C2 provide phase compensation to help prevent overshoot and ringing when high-speed op amps are used.

For zero offset adjustment, the appropriate DAC register is loaded with all 0 s and amplifier offset adjusted so that $V_{\text {OUTA }}$ or $V_{\text {OUTB }}$ is 0 V . Full-scale trimming is accomplished by loading the DAC register with all 1 s and adjusting R 1 (R3) so that $\mathrm{V}_{\text {OUTA }}$ ( $\mathrm{V}_{\text {OUTB }}$ ) $=-\mathrm{V}_{\text {IN }}(4095 / 4096)$. For high temperature operation, resistors and potentiometers should have a low Temperature Coefficient. In many applications, because of the excellent Gain T.C. and Gain Error specifications of the AD7937, Gain Error trimming is not necessary. In fixed reference applications, full scale can also be adjusted by omitting R1, R2, R3, R4 and trimming the reference voltage magnitude.

Figure 4. Unipolar Binary Operation
Table II. Unipolar Binary Code Table for Circuit of Figure 4

| Binary Number in <br> DAC Register <br> MSB LSB | Analog Output, <br> $\mathbf{V}_{\text {OUTA or V }}^{\text {OUTB }}$ |
| :--- | :--- |
| 111111111111 | $-V_{\text {IN }}\left(\frac{4095}{4096}\right)$ |
| 100000000000 | $-V_{I N}\left(\frac{2048}{4096}\right)=-1 / 2 V_{\text {IN }}$ |
| 000000000001 | $-V_{I N}\left(\frac{1}{4096}\right)$ |
| 000000000000 | $0 V$ |

## BIPOLAR OPERATION

## (4-QUADRANT MULTIPLICATION)

The recommended circuit diagram for bipolar operation is shown in Figure 5. Offset binary coding is used.
With the appropriate DAC register loaded to 100000000000 , adjust R1 (R3) so that $\mathrm{V}_{\text {OUTA }}\left(\mathrm{V}_{\text {OUTB }}\right)=0 \mathrm{~V}$. Alternatively, R1, R2 (R3, R4) may be omitted and the ratios of R6, R7 (R9, R10) varied for $\mathrm{V}_{\text {OUTA }}\left(\mathrm{V}_{\text {OUTB }}\right)=0 \mathrm{~V}$. Full-scale trimming can be accomplished by adjusting the amplitude of $\mathrm{V}_{\mathrm{IN}}$ or by varying the value of R5 (R8).
If R1, R2 (R3, R4) are not used, then resistors R5, R6, R7 (R8, $\mathrm{R} 9, \mathrm{R} 10$ ) should be ratio matched to $0.01 \%$ to ensure gain error performance to the data sheet specification. When operating over a wide temperature range, it is important that the resistors be of the same type so that their temperature coefficients match.

The code table for Figure 5 is given in Table III.

Figure 5. Bipolar Operation (Offset Binary Coding)
Table III. Bipolar Code Table for Offset Binary Circuit of Figure 5

| Binary Number in <br> DAC Register <br> MSB LSB | Analog Output, <br> $\mathbf{V}_{\text {OUTA }}$ or $\mathbf{V}_{\text {OUTB }}$ |

| 000000000000 | $-V_{I N}\left(\frac{2048}{2048}\right)=-V_{I N}$ |

## SEPARATE AGND PINS

The DACs in the AD7937 have separate AGND lines taken to pins AGNDA and AGNDB on the package. This increases the applications versatility of the part. Figure 6 is an example of this. DAC A is connected in standard fashion as a programmable attenuator. AGNDA is at ground potential. DAC B is operating with AGND B biased to 5 V by the AD584. This gives an output range of 5 V to 10 V .

Figure 6. DACs Used in Different Modes

## PROGRAMMABLE OSCILLATOR

Figure 7 shows a conventional state variable oscillator in which the AD7937 controls the programmable integrators. The frequency of oscillation is given by:

$$
f=\frac{1}{2 \pi} \sqrt{\frac{R 6}{R 5} \times \frac{1}{C 1 \times C 2 \times R_{E Q 1} \times R_{E Q 2}}}
$$

where $\mathrm{R}_{\mathrm{EQ} 1}$ and $\mathrm{R}_{\mathrm{EQ} 2}$ are the equivalent resistances of the DACs. The same digital code is loaded into both DACs. If C1 = C2 and $\mathrm{R} 5=\mathrm{R} 6$, the expression reduces to

$$
f=\frac{1}{2 \pi} \times \frac{1}{C} \sqrt{\frac{1}{R_{E Q 1} \times R_{E Q 2}}}
$$

Since $R_{E Q}=\frac{2^{n} \times R_{L A D}}{N},\left(\mathrm{R}_{\mathrm{LAD}}=\mathrm{DAC}\right.$ ladder resistance $)$.

$$
\begin{aligned}
& f=\frac{1}{2 \pi} \times \frac{1}{C} \sqrt{\frac{\left(N / 2^{n}\right)^{2}}{R_{L A D 1} \times R_{L A D 2}}} \\
& =\frac{1}{2 \pi} \times \frac{D}{C} \frac{1}{\sqrt{R_{L A D 1} \times R_{L A D 2}}} \quad D=\left(\frac{N}{2^{n}}\right) \\
& =\frac{1}{2 \pi} \times \frac{D}{C \times R_{L A D \sqrt{m}}}
\end{aligned}
$$

where $m$ is the DAC ladder resistance mismatch ratio, typically 1.005 .

With the values shown in Figure 7, the output frequency varies from 0 Hz to 1.38 kHz . The amplitude of the output signal at the A3 output is 10 V peak-to-peak and is constant over the entire frequency span.

Figure 7. Programmable State Variable Oscillator

## APPLICATION HINTS

Output Offset: CMOS D/A converters in circuits such as Figures 4 and 5 exhibit a code-dependent output resistance which in turn can cause a code-dependent error voltage at the output of the amplifier. The maximum amplitude of this error, which adds to the $\mathrm{D} / \mathrm{A}$ converter nonlinearity, depends on $\mathrm{V}_{\mathrm{OS}}$, where $\mathrm{V}_{\mathrm{OS}}$ is the amplifier input offset voltage. To maintain specified operation, it is recommended that $\mathrm{V}_{\mathrm{OS}}$ be no greater than $\left(25 \times 10^{-6}\right)\left(\mathrm{V}_{\mathrm{REF}}\right)$ over the temperature range of operation. Suitable op amps are the AD711C and its dual version, the AD712C. These op amps have a wide bandwidth and high slew rate and are recommended for wide bandwidth ac applications. AD711/AD712 settling time to $0.01 \%$ is typically $3 \mu \mathrm{~s}$.
Temperature Coefficients: The gain temperature coefficient of the AD7937 has a maximum value of $5 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ and typical value of $1 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$. This corresponds to worst case gain shifts of 2 LSBs and 0.4 LSB respectively over a $100^{\circ} \mathrm{C}$ temperature range. When trim resistors R1 (R3) and R2 (R4) are used to adjust full scale range as in Figure 4, the temperature coefficient of R1 (R3) and R2 (R4) should also be taken into account.
High Frequency Considerations: AD7937 output capacitance works in conjunction with the amplifier feedback resistance to add a pole to the open-loop response. This can cause ringing or oscillation. Stability can be restored by adding a phase compensation capacitor in parallel with the feedback resistor. This is shown as C 1 and C 2 in Figures 4 and 5.
Feedthrough: The dynamic performance of the AD7937 depends upon the gain and phase stability of the output amplifier, together with the optimum choice of PC board layout and decoupling components.

## MICROPROCESSOR INTERFACING

The byte loading structure of the AD7937 makes it very easy to interface the device to any 8 -bit microprocessor system. Figure 8 shows an example 8 -bit interface between the AD7937 and a generic 8-bit microcontroller/DSP processor. Pins D7 to D0 of the processor are connected to pins D7 to D0 of the AD7937. When writing to the DACs, the lower 8 bits must be written first, followed by the upper four bits. The upper four bits should be output on data lines D0 to D3.
