

SELF-OSCILLATING HALF-BRIDGE DRIVER IC

Features

- Integrated 600 V half-bridge gate driver
- C_T , R_T programmable oscillator
- 15.4 V Zener clamp on V_{CC}
- Micropower startup
- Non-latched shutdown on C_T pin ($1/6$ th V_{CC})
- Internal bootstrap FET
- Excellent latch immunity on all inputs and outputs
- +/- 50 V/ns dV/dt immunity
- ESD protection on all pins
- 8-lead SOIC or PDIP package
- Internal deadtime

Product Summary

| | |
|----------------------------|---|
| V_{OFFSET} | 600 V Max |
| Duty cycle | 50% |
| Driver source/sink current | 180 mA/260 mA typ. |
| V_{clamp} | 15.4 V typ. |
| Deadtime | 1.1 μ s typ. (IRS2153D) 0.6 μ s typ. (IRS21531D) |

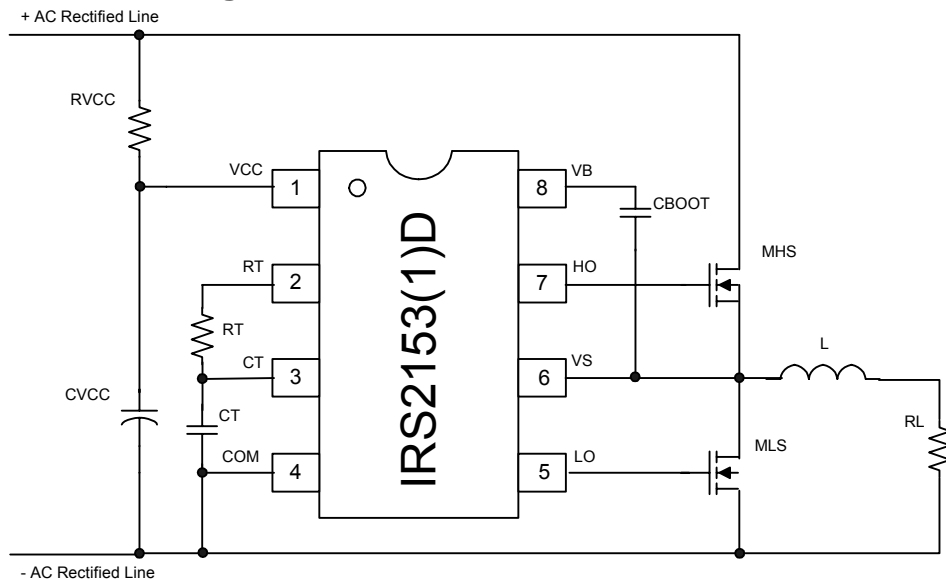

Description

The IRS2153(1)D is based on the popular IR2153 self-oscillating half-bridge gate driver IC using a more advanced silicon platform, and incorporates a high voltage half-bridge gate driver with a front end oscillator similar to the industry standard CMOS 555 timer. HVIC and latch immune CMOS technologies enable rugged monolithic construction. The output driver features a high pulse current buffer stage designed for minimum driver cross-conduction. Noise immunity is achieved with low di/dt peak of the gate drivers.

Package

Typical Connection Diagram

Absolute Maximum Ratings

Absolute maximum ratings indicate sustained limits beyond which damage to the device may occur. All voltage parameters are absolute voltages referenced to COM, all currents are defined positive into any lead. The thermal resistance and power dissipation ratings are measured under board mounted and still air conditions.

| Parameter | | Min. | Max. | Units |
|------------|--|-------------|----------------|--------------------|
| Symbol | Definition | | | |
| V_B | High side floating supply voltage | -0.3 | 625 | V |
| V_S | High side floating supply offset voltage | $V_B - 25$ | $V_B + 0.3$ | |
| V_{HO} | High side floating output voltage | $V_S - 0.3$ | $V_B + 0.3$ | |
| V_{LO} | Low side output voltage | -0.3 | $V_{CC} + 0.3$ | |
| I_{RT} | R_T pin current | -5 | 5 | mA |
| V_{RT} | R_T pin voltage | -0.3 | $V_{CC} + 0.3$ | V |
| V_{CT} | C_T pin voltage | -0.3 | $V_{CC} + 0.3$ | |
| I_{CC} | Supply current (Note 1) | --- | 20 | mA |
| I_{OMAX} | Maximum allowable current at LO and HO due to external power transistor Miller effect. | -500 | 500 | |
| dV_S/dt | Allowable offset voltage slew rate | -50 | 50 | V/ns |
| P_D | Maximum power dissipation @ $T_A \leq +25\text{ }^\circ\text{C}$, 8-Pin DIP | --- | 1.0 | W |
| P_D | Maximum power dissipation @ $T_A \leq +25\text{ }^\circ\text{C}$, 8-Pin SOIC | --- | 0.625 | |
| R_{thJA} | Thermal resistance, junction to ambient, 8-Pin DIP | --- | 85 | $^\circ\text{C/W}$ |
| R_{thJA} | Thermal resistance, junction to ambient, 8-Pin SOIC | --- | 128 | |
| T_J | Junction temperature | -55 | 150 | $^\circ\text{C}$ |
| T_S | Storage temperature | -55 | 150 | |
| T_L | Lead temperature (soldering, 10 seconds) | --- | 300 | |

Note 1: This IC contains a zener clamp structure between the chip V_{CC} and COM which has a nominal breakdown voltage of 15.4 V. Please note that this supply pin should not be driven by a DC, low impedance power source greater than the V_{CLAMP} specified in the Electrical Characteristics section.

Recommended Operating Conditions

For proper operation the device should be used within the recommended conditions.

| Parameter | | Min. | Max. | Units |
|-----------------|--|----------------------------|-----------------------|-------|
| Symbol | Definition | | | |
| V _{BS} | High side floating supply voltage | V _{CC} - 0.7 | V _{CLAMP} | V |
| V _S | Steady state side floating supply offset voltage | -3.0 (Note 2) | 600 | |
| V _{CC} | Supply voltage | V _{CCUV+} + 0.1 V | V _{CC CLAMP} | |
| I _{CC} | Supply current | (Note 3) | 5 | mA |
| T _J | Junction temperature | -40 | 125 | °C |

Note 2: It is recommended to avoid output switching conditions where the negative-going spikes at the V_S node would decrease V_S below ground by more than -5 V.

Note 3: Enough current should be supplied to the V_{CC} pin of the IC to keep the internal 15.6 V zener diode clamping the voltage at this pin.

Recommended Component Values

| Parameter | | Min. | Max. | Units |
|----------------|------------------------------------|------|------|-------|
| Symbol | Component | | | |
| R _T | Timing resistor value | 1 | --- | kΩ |
| C _T | C _T pin capacitor value | 330 | --- | pF |

V_{BIAS} (V_{CC}, V_{BS}) = 14 V, V_S=0 V and T_A = 25 °C, C_{LO} = C_{HO} = 1 nF.

For further information, see Fig. 12.

Electrical Characteristics

V_{BIAS} (V_{CC} , V_{BS}) = 14 V, C_T = 1 nF, V_S = 0 V and T_A = 25 °C unless otherwise specified. The output voltage and current (V_o and I_o) parameters are referenced to COM and are applicable to the respective output leads: HO or LO. CLO = CHO = 1 nF.

| Symbol | Definition | Min | Typ | Max | Units | Test Conditions |
|---|---|------|------|------|---------|---|
| Low Voltage Supply Characteristics | | | | | | |
| V_{CCUV+} | Rising V_{CC} undervoltage lockout threshold | 10.0 | 11.0 | 12.0 | V | |
| V_{CCUV-} | Falling V_{CC} undervoltage lockout threshold | 8.0 | 9.0 | 10.0 | | |
| $V_{CCUVHYS}$ | V_{CC} undervoltage lockout hysteresis | 1.6 | 2.0 | 2.4 | | |
| I_{QCCUV} | Micropower startup V_{CC} supply current | --- | 130 | 170 | μ A | $V_{CC} \leq V_{CCUV-}$ |
| I_{QCC} | Quiescent V_{CC} supply current | --- | 800 | 1000 | | |
| I_{CC} | V_{CC} supply current | --- | 1.8 | --- | mA | $R_T = 36.9 \text{ k}\Omega$ |
| $V_{CCCLAMP}$ | V_{CC} zener clamp voltage | 14.4 | 15.4 | 16.8 | V | $I_{CC} = 5 \text{ mA}$ |
| Floating Supply Characteristics | | | | | | |
| I_{QBS} | Quiescent V_{BS} supply current | --- | 60 | 80 | μ A | |

Functional Description

Under-voltage Lock-Out Mode (UVLO)

The under-voltage lockout mode (UVLO) is defined as the state the IC is in when V_{CC} is below the turn-on threshold of the IC. The IRS2153(1)D under voltage lock-out is designed to maintain an ultra low supply current of less than 170 μ A, and to guarantee the IC is fully functional before the high and low side output drivers are activated. During under voltage lock-out mode, the high and low-side driver outputs HO and LO are both low.

Supply voltage

Fig. 1 Typical Connection Diagram

Fig. 1 shows an example of supply voltage. The start-up capacitor (C_{VCC}) is charged by current through supply resistor (R_{VCC}) minus the start-up current drawn by the IC. This resistor is chosen to provide sufficient current to supply the IRS2153(1)D from the DC bus. C_{VCC} should be large enough to hold the voltage at V_{CC} above the UVLO threshold for one half cycle of the line voltage as it will only be charged at the peak, typically 0.1 μ F. It will be necessary for R_{VCC} to dissipate around 1 W.

The use of a two diode charge pump made of DC1, DC2 and CVS (Fig. 2) from the half bridge (V_S) is also possible however the above approach is simplest and the dissipation in R_{VCC} should not be unacceptably high.

Fig. 2 Charge pump circuit

The supply resistor (R_{VCC}) must be selected such that enough supply current is available over all operating conditions.

Once the capacitor voltage on V_{CC} reaches the start-up threshold V_{CCUV+} , the IC turns on and HO and LO begin to oscillate.

Bootstrap MOSFET

The internal bootstrap FET and supply capacitor (C_{BOOT}) comprise the supply voltage for the high side driver circuitry. The internal bootstrap FET only turns on when LO is high. To guarantee that the high-side supply is charged up before the first pulse on pin HO, the first pulse from the output drivers comes from the LO pin.

Normal operating mode

Once the V_{CCUV+} threshold is passed, the MOSFET M1 opens, RT increases to approximately V_{CC} ($V_{CC}-V_{RT+}$) and the external CT capacitor starts charging. Once the CT voltage reaches V_{CT-} (about 1/3 of V_{CC}), established by an internal resistor ladder, LO turns on with a delay equivalent to the deadtime (t_d). Once the CT voltage reaches V_{CT+} (approximately 2/3 of V_{CC}), LO goes low, RT goes down to approximately ground (V_{RT-}), the CT capacitor discharges and the deadtime circuit is activated. At the end of the deadtime, HO goes high. Once the CT voltage reaches V_{CT-} , HO goes low, RT goes high again, the deadtime is activated. At the end of the deadtime, LO goes high and the cycle starts over again.

The following equation provides the oscillator frequency:

$$f \sim \frac{1}{1.453 \times RT \times CT}$$

This equation can vary slightly from actual measurements due to internal comparator over- and under-shoot delays. For a more accurate determination of the output frequency, the frequency characteristic curves should be used (RT vs. Frequency, page 3).

Shut-down

If CT is pulled down below V_{CTSD} (approximately 1/6 of V_{CC}) by an external circuit, CT doesn't charge up and oscillation stops. LO is held low and the bootstrap FET is off. Oscillation will resume once CT is able to charge up again to V_{CT-} .
