A.C. motor control circuit

HEF4752V LSI

DESCRIPTION

The HEF4752V is a circuit for a.c. motor speed control utilizing LOCMOS technology. The circuit synthesizes three 120° out of phase signals, of which the average voltage varies sinusoidally with time in the frequency range 0 to 200 Hz. The method employed is based upon the pulse width modulation principle, in order to achieve a sufficient accuracy of the output voltages over the whole frequency range. A pure digital waveform generation is used.

All outputs are of the push-pull type. Inputs and outputs are protected against electrostatic effects in a wide variety of device-handling situations. However, to be totally safe, it is desirable to take handling precautions into account.

HEF4752V LSI

APPLICATION INFORMATION

Figure 2 shows the functional block diagram of a 3-phase a.c. motor speed control system using a thyristorized inverter with variable frequency output. The inverter control signals are generated by the HEF4752V (PWM-IC). A special feature of the PWM (Pulse-Width Modulation) - IC is here, that the motor is supplied by sinusoidally modulated pulses, hence the resulting motor current will approach a sine-wave with a minimum on higher harmonics. In this way, an optimum speed drive with high performance is obtained.

Furthermore, the HEF4752V contains all logic circuitry required for this special waveform generation, so that the amount of control circuit components is reduced considerable. The speed drive system in Fig.2 is controlled by the analogue control section.

The FCT and VCT clock pulse oscillators are driven in such a way, that a fast response speed control of the a.c. motor is obtained, depending on: the reference values for speed; motor voltage; motor current (Limited by the measured motor current via DCCT - d.c. current transformer -); the increasing value of V_{Cb} during braking action.
