

## Four-Channel Programmable Digital DownConverter

The ISL5216 Quad Programmable Digital DownConverter (QPDC) is designed for high dynamic range applications such as cellular basestations where multiple channel processing is required in a small physical space. The QPDC combines into a single package a set of four channels which include: digital mixers, a quadrature carrier NCO, digital filters, a resampling filter, a Cartesian-to-polar coordinate converter and an AGC loop.

The ISL5216 accepts four channels of 16-bit fixed or up to 14-bit mantissa / 3-bit exponent floating point real or complex digitized IF samples which are mixed with local quadrature sinusoids. Each channel carrier NCO frequency is set independently by the microprocessor. The output of the mixers are filtered with a CIC and FIR filters, with a variety of decimation options. Gain adjustment is provided on the filtered signal. The digital AGC provides a gain adjust range of up to 96dB with programmable thresholds and slew rates. A cartesian to polar coordinate converter provides magnitude and phase outputs. A frequency discriminator is also provided to allow FM demodulation. Selectable outputs include I samples, Q samples, Magnitude, Phase, Frequency and AGC gain. The output resolution is selectable from 4-bit fixed point to 32-bit floating point.

Output bandwidths in excess of 1MHz are achievable using a single channel. Wider bandwidths are available by cascading or polyphasing multiple channels.

## Features

- Up to 95MSPS Input
- Four Independently Programmable Downconverter Channels in a single package
- Four Parallel 17-Bit Inputs providing 16-bit fixed or one of several 17-bit floating point formats
- 32-Bit Programmable Carrier NCO with > 115dB SFDR
- 110dB FIR Out of Band Attenuation
- Decimation from 4 to >65536
- 24-bit Internal Data Path
- Digital AGC with up to 96dB of Gain Range
- Filter Functions
  - 1- to 5-Stage CIC Filter
  - Halfband Decimation and Interpolation FIR Filtering
  - Programmable FIR Filtering
  - Resampling FIR Filtering
- Cascadable Filtering for Additional Bandwidth
- Four Independent Serial Outputs
- 2.5V Core, 3.3V I/O Operation
- Pb-Free Plus Anneal Available (RoHS Compliant)

## Applications

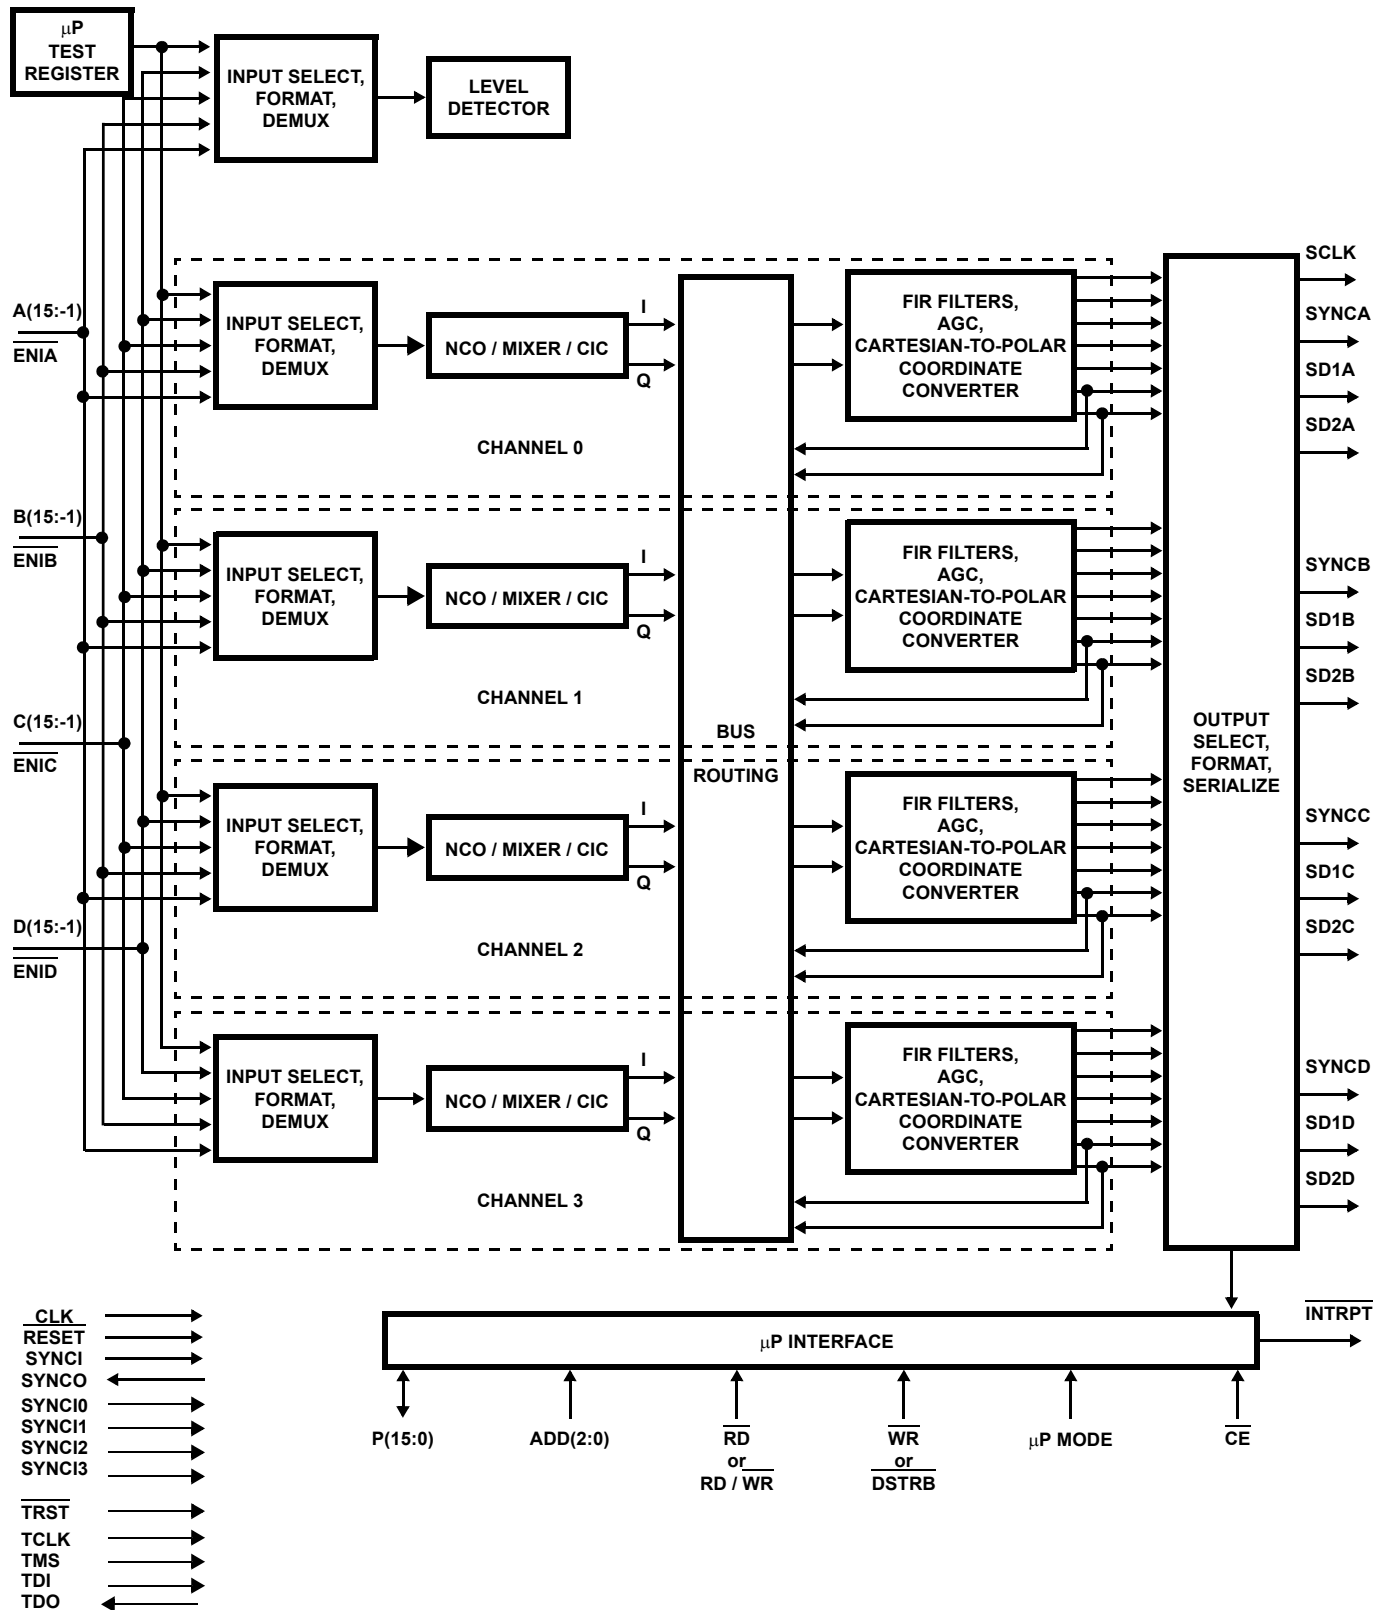

- Narrow-Band TDMA through IS-95 CDMA Digital Software Radio and Basestation Receivers
- Wide-Band Applications: W-CDMA and UMTS Digital Software Radio and Basestation Receivers

## Ordering Information

PART NUMBER	TEMP RANGE (°C)	PACKAGE	PKG. DWG. #
ISL5216KI	-40 to 85	196 Ld 0.8 mm BGA	V196.12x12
ISL5216KI-1	-40 to 85	196 Ld 1.0 mm BGA	V196.15x15
ISL5216KIZ (See Note)	-40 to 85	196 Ld 0.8 mm BGA (Pb-free)	V196.12x12
ISL5216KI-1Z (See Note)	-40 to 85	196 Ld 1.0 mm BGA (Pb-free)	V196.15x15

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

## Pin Descriptions

NAME	TYPE	DESCRIPTION
<b>POWER SUPPLY</b>		
VCC1	-	Positive Power Supply Voltage (core), 2.5V $\pm$ 0.125
VCC2	-	Positive Power Supply Voltage (I/O), 3.3V $\pm$ 0.165
GND	-	Ground, 0V.
<b>INPUTS</b>		
A(15:0), Am1	I	Parallel Data Input bus A. Sampled on the rising edge of clock when $\overline{\text{ENIA}}$ is active (low). Am1 has internal weak pull down.
B(15:0), Bm1	I	Parallel Data Input bus B. Sampled on the rising edge of clock when $\overline{\text{ENIB}}$ is active (low). Bm1 has internal weak pull down.
C(15:0), Cm1	I	Parallel Data Input bus C. Sampled on the rising edge of clock when $\overline{\text{ENIC}}$ is active (low). Cm1 has internal weak pull down.
D15	I	Parallel Data Input D15 or tuner channel 0 COF.
D14	I	Parallel Data Input D14 or tuner channel 0 COFSync.
D13	I	Parallel Data Input D13 or tuner channel 0 SOF.
D12	I	Parallel Data Input D12 or tuner channel 0 SOFSync.
D11	I	Parallel Data Input D11 or tuner channel 1 COF.
D10	I	Parallel Data Input D10 or tuner channel 1 COFSync.
D9	I	Parallel Data Input D9 or tuner channel 1 SOF.
D8	I	Parallel Data Input D8 or tuner channel 1 SOFSync.
D7	I	Parallel Data Input D7 or tuner channel 2 COF.
D6	I	Parallel Data Input D6 or tuner channel 2 COFSync.
D5	I	Parallel Data Input D5 or tuner channel 2 SOF.
D4	I	Parallel Data Input D4 or tuner channel 2 SOFSync.
D3	I	Parallel Data Input D3 or tuner channel 3 COF.
D2	I	Parallel Data Input D2 or tuner channel 3 COFSync.
D1	I	Parallel Data Input D1 or tuner channel 3 SOF.
D0	I	Parallel Data Input D0 or tuner channel 3 SOFSync.
Dm1	I	Parallel Data Input Dm1 for extended floating point input modes. Dm1 has internal weak pull down.
$\overline{\text{ENIA}}$	I	Input enable for Parallel Data Input bus A. Active low. This pin enables the input to the part in one of two modes, gated or interpolated. In gated mode, one sample is taken per CLK when $\overline{\text{ENI}}$ is asserted.
$\overline{\text{ENIB}}$	I	Input enable for Parallel Data Input bus B. Active low. This pin enables the input to the part in one of two modes, gated or interpolated. In gated mode, one sample is taken per CLK when $\overline{\text{ENI}}$ is asserted.
$\overline{\text{ENIC}}$	I	Input enable for Parallel Data Input bus C. Active low. This pin enables the input to the part in one of two modes, gated or interpolated. In gated mode, one sample is taken per CLK when $\overline{\text{ENI}}$ is asserted.
$\overline{\text{ENID}}$	I	Input enable for Parallel Data Input bus D. Active low. This pin enables the input to the part in one of two modes, gated or interpolated. In gated mode, one sample is taken per CLK when $\overline{\text{ENI}}$ is asserted.
<b>CONTROL</b>		
CLK	I	Input clock. All processing in the ISL5216 occurs on the rising edge of CLK.
SYNCI	I	Global synchronization input signal. Used to align the processing with an external event or with other ISL5216 or HSP50216 devices. SYNCI can update the carrier NCO, reset decimation counters, restart the filter compute engine, and restart the output section among other functions. For most of the functional blocks, the response to SYNCI is programmable and can be enabled or disabled. This signal is connected to all four channels and is included for backward compatibility with HSP50216 designs.
SYNCI0	I	Synchronization input signal for channel 0. Same functions as SYNCI but connects only to channel 0. This pin is internally pulled low to allow it to be left unconnected.
SYNCI1	I	Synchronization input signal for channel 1. Same functions as SYNCI but connects only to channel 1. This pin is internally pulled low to allow it to be left unconnected.
SYNCI2	I	Synchronization input signal for channel 2. Same functions as SYNCI but connects only to channel 2. This pin is internally pulled low to allow it to be left unconnected.

**Pin Descriptions** (Continued)

NAME	TYPE	DESCRIPTION
SYNCI3	I	Synchronization input signal for channel 3. Same functions as SYNCI but connects only to channel 3. This pin is internally pulled low to allow it to be left unconnected.
SYNCO	O	Synchronization Output Signal. The processing of multiple ISL5216 or HSP50216 devices can be synchronized by tying the SYNCO from one ISL5216 device (the master) to the SYNCI of all the ISL5216 / HSP50216 devices (the master and slaves).
$\overline{\text{RESET}}$	I	Reset Signal. Active low. Asserting reset will halt all processing and set certain registers to default values.
<b>JTAG</b>		
TDO	O	Test data out
TDI	I	Test data in. Contains weak internal pull up.
TMS	I	Test mode select. Contains weak internal pull up.
TCLK	I	Test clock. Contains weak internal pull down.
$\overline{\text{TRST}}$	I	Test reset. Active low. Contains weak internal pull down.
<b>OUTPUTS</b>		
SD1A	O	Serial Data Output 1A. A serial data stream output which can be programmed to consist of I1, Q1, I2, Q2, magnitude, phase, frequency (d $\phi$ /dt), AGC gain, and/or zeros. In addition, data outputs from Channels 0, 1, 2 and 3 can be multiplexed into a common serial output data stream. Information can be sequenced in a programmable order. See <i>Serial Data Output Formatter Section and Microprocessor Interface Section</i> .
SD2A	O	Serial Data Output 2A. This output is provided as an auxiliary output for Serial Data Output 1A to route data to a second destination or to output two words at a time for higher sample rates. SD2A has the same programmability as SD1A except that floating point format is not available. See <i>Serial Data Output Formatter Section and Microprocessor Interface Section</i> .
SD1B	O	Serial Data Output 1B. See description for SD1A.
SD2B	O	Serial Data Output 2B. See description for SD2A.
SD1C	O	Serial Data Output 1C. See description for SD1A.
SD2C	O	Serial Data Output 2C. See description for SD2A.
SD1D	O	Serial Data Output 1D. See description for SD1A.
SD2D	O	Serial Data Output 2D. See description for SD2A.
SCLK	O	Serial Output Clock. Can be programmed to be at 1, 1/2, 1/4, 1/8, or 1/16 times the clock frequency. The polarity of SCLK is programmable.
SYNCA	O	Serial Data Output 1A sync signal. This signal is used to indicate the start of a data word and/or frame of data. The polarity and position of SYNCA is programmable.
SYNCB	O	Serial Data Output 1B sync signal. This signal is used to indicate the start of a data word and/or frame of data. The polarity and position of SYNCB is programmable.
SYNCC	O	Serial Data Output 1C sync signal. This signal is used to indicate the start of a data word and/or frame of data. The polarity and position of SYNCC is programmable.
SYNCD	O	Serial Data Output 1D sync signal. This signal is used to indicate the start of a data word and/or frame of data. The polarity and position of SYNCD is programmable.
<b>MICROPROCESSOR INTERFACE</b>		
P(15:0)	I/O	Microprocessor Interface Data bus. See <i>Microprocessor Interface Section</i> . P15 is the MSB.
ADD(2:0)	I	Microprocessor Interface Address bus. ADD2 is the MSB. See <i>Microprocessor Interface Section</i> . Note: ADD2 <b>is not</b> used but designated for future expansion.
$\overline{\text{WR}}$ or $\overline{\text{DSTRB}}$	I	Microprocessor Interface Write or Data Strobe Signal. When the Microprocessor Interface Mode Control, $\mu\text{P MODE}$ , is a low data transfers (from either P(15:0) to the internal write holding register or from the internal write holding register to the target register specified) occur on the low to high transition of $\overline{\text{WR}}$ when $\overline{\text{CE}}$ is asserted (low). When the $\mu\text{P MODE}$ control is high this input functions as a data read/write strobe. In this mode with $\overline{\text{RD}}/\overline{\text{WR}}$ low data transfers (from either P(15:0) to the internal write holding register or from the internal write holding register to the target register specified) occur on the low to high transition of Data Strobe. With $\overline{\text{RD}}/\overline{\text{WR}}$ high the data from the address specified is placed on P(15:0) when Data Strobe is low. See <i>Microprocessor Interface Section</i> .

**Pin Descriptions** (Continued)

NAME	TYPE	DESCRIPTION
$\overline{RD}$ or $\overline{RD/\overline{WR}}$	I	Microprocessor Interface Read or Read/ $\overline{Write}$ Signal. When the Microprocessor Interface Mode Control, $\mu P$ MODE, is a low the data from the address specified is placed on P(15:0) when $\overline{RD}$ is asserted (low) and $\overline{CE}$ is asserted (low). When the $\mu P$ MODE control is high this input functions as a Read/ $\overline{Write}$ control input. Data is read from P(15:0) when high or written to the appropriate register when low. See <i>Microprocessor Interface Section</i> .
$\mu P$ MODE	I	Microprocessor Interface Mode Control. This pin is used to select the Read/Write mode for the Microprocessor Interface. Internally pulled down. See <i>Microprocessor Interface Section</i> .
$\overline{CE}$	I	Microprocessor Interface Chip Select. Active low. This pin has the same timing as the address pins.
$\overline{INTRPT}$	O	Microprocessor Interrupt Signal. Asserted for a programmable number of clock cycles when new data is available on the selected Channel.

**Functional Description**

The ISL5216 is a 4-channel digital receiver integrated circuit offering exceptional dynamic range and flexibility. Each of the four channels consists of a front-end NCO, digital mixer, and CIC-filter block and a back-end FIR, AGC and Cartesian to polar coordinate-conversion block. The parameters for the four channels are independently programmable. Four 17-bit parallel data input busses (A(15:-1), B(15:-1), C(15:-1) and D(15:-1)) and four pairs of serial data outputs (SDxA, SDxB, SDxC, and SDxD; x = 1 or 2) are provided. Each input can be connected to any or all of the internal signal processing channels, Channels 0, 1, 2 and 3. The output of each channel can be routed to any of the serial outputs. Outputs from more than one channel can be multiplexed through a common output if the channels are synchronized. The four channels share a common input clock and a common serial output clock, but the output sample rates can be synchronous or asynchronous. Bus multiplexers between the front end and back end sections provide flexible routing between channels for cascading back-end filters or for routing one front end to multiple back ends for polyphase filtering or systolic arrays (to provide wider bandwidth filtering). A level detector is provided to monitor the signal level on any of the parallel data input busses, facilitating microprocessor control of gain blocks prior to an A/D converter.

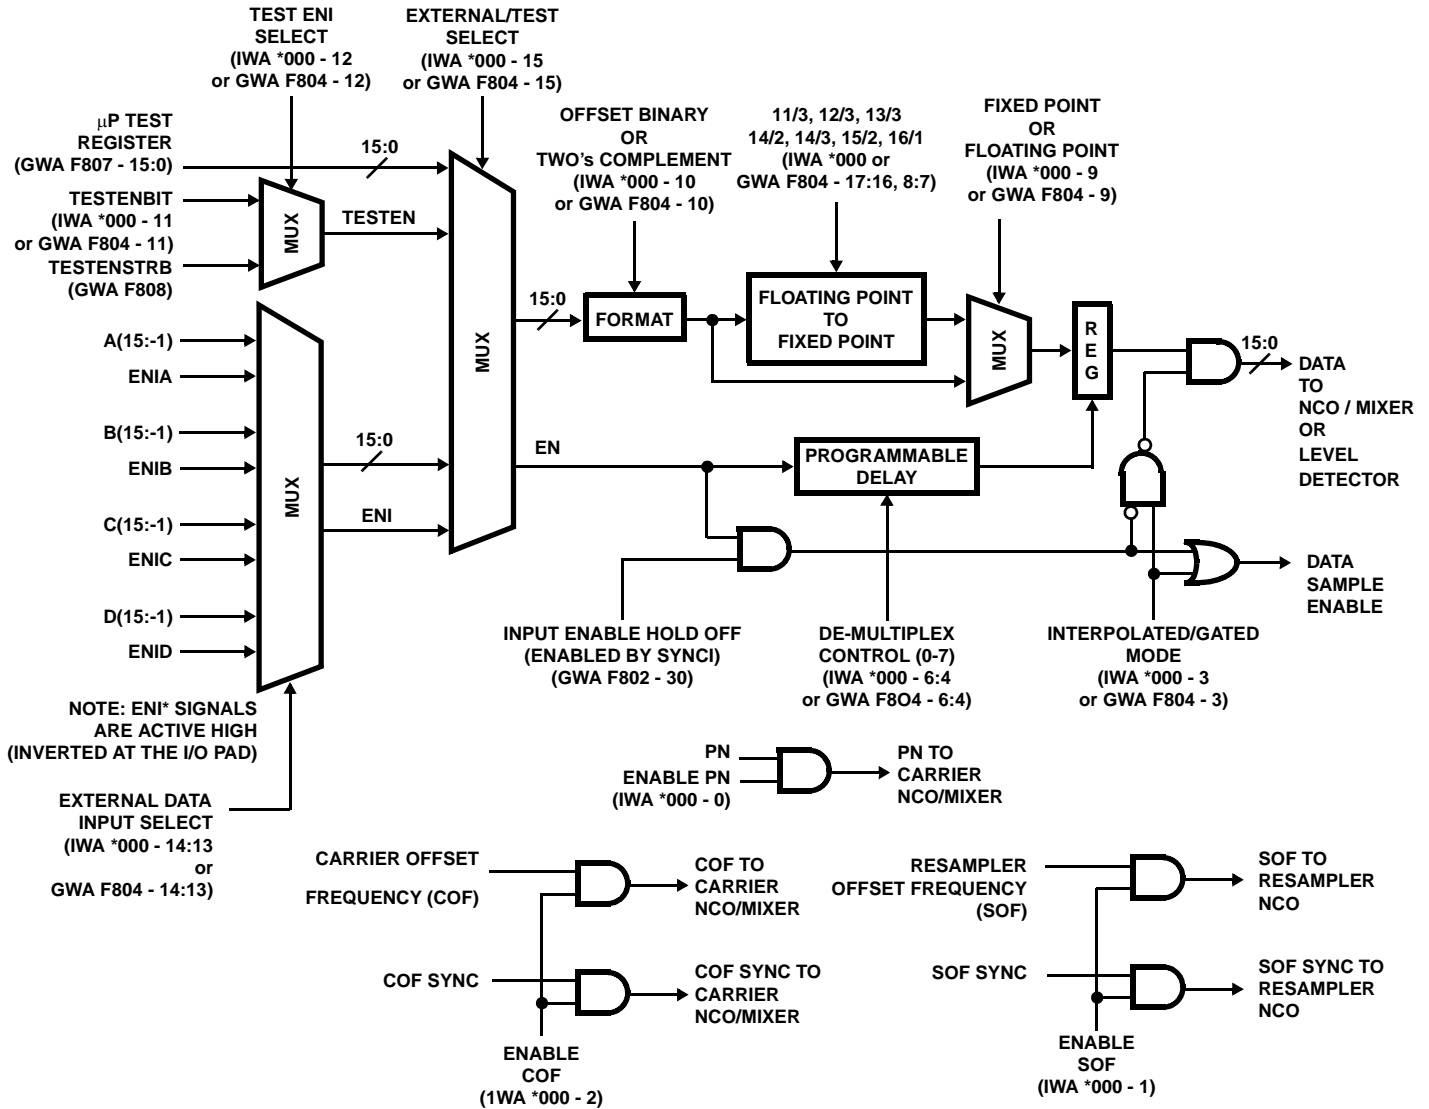

Each front end NCO/digital mixer/CIC filter section includes a quadrature numerically controlled oscillator (NCO), digital mixer, barrel shifter and a cascaded-integrator-comb filter (CIC). The NCO has a 32-bit frequency control word for 22.1milihertz tuning resolution at an input sample rate of 95MSPS. The SFDR of the NCO is >115dB. The CIC filter order is programmable between 1 and 5 and the CIC decimation factor can be programmed from 4 to 512 for 5<sup>th</sup> order, 2048 for 4<sup>th</sup> order, 32768 for 3<sup>rd</sup> order, or 65536 for 1<sup>st</sup> or 2<sup>nd</sup> order filters.

Each channel back end section includes an FIR processing block, an AGC and a cartesian-to-polar coordinate converter. The FIR processing block is a flexible filter compute engine that can compute a single FIR or a set of cascaded decimating, interpolating or resampling filters. A single filter in a chain can have up to 256 taps and the total number of taps in a set of filters can be up to 384 provided that the decimation is sufficient. The ISL5216 calculates two taps per clock (on each channel) for symmetric filters, generally making decimation the limiting factor for the number of taps available. The filter compute engine supports a variety of filter types including decimation, interpolation and resampling filters. The coefficients for the programmable digital filters are 22 bits wide. Coefficients are provided in ROM for several halfband filter responses and for a resampler. The AGC section can provide up to 96dB of either fixed or automatic gain control. For automatic gain control, two settling modes and two sets of loop gains are provided. Separate attack and decay slew rates are provided for each loop gain. Programmable limits allow the user to select a gain range less than 96dB. The outputs of the cartesian-to-polar coordinate conversion block, used by the AGC loop, are also provided as outputs to the user for AM and FM demodulation.

The ISL5216 supports both fixed and floating point parallel data input modes. The floating point modes support gain ranging A/D converters. Gated, interpolated and multiplexed data input modes are supported. The serial data output word width for each data type can be programmed to one of ten output bit widths from 4-bit fixed point through 32-bit IEEE 754 floating point.

The ISL5216 is programmed through a 16-bit microprocessor interface. The output data can also be read via the microprocessor interface for all channels that are synchronized. The ISL5216 is specified to operate to a maximum clock rate of 95MSPS over the industrial temperature range (-40°C to 85°C). The I/O power supply voltage range is 3.3V  $\pm$  0.165V while the core power supply voltage is 2.5V  $\pm$  0.125V. The I/Os are 5V tolerant.

**Input Select/Format Block**

Each front end block and the level detector block contains an input select/format block. A functional block diagram is provided in the above figure. The input source can be any of the four parallel input busses (see *Microprocessor Interface Section Table 1, IWA \*000h*) or a test register loaded via the processor bus (see *Microprocessor Interface Section, GWA register F807h*).

The input to the part can operate in a gated or interpolated mode. Each input data bus has an input enable ( $\overline{ENIx}$ ,  $x = A, B, C$  or  $D$ ). In the gated mode, one input sample is processed per clock that the  $\overline{ENIx}$  signal is asserted (low). Processing is disabled when  $\overline{ENIx}$  is high. The  $\overline{ENIx}$  signal is pipelined through the part to minimize delay (latency). In the interpolated mode, the input is zeroed when the  $\overline{ENIx}$  signal is high, but processing inside the part continues. This mode inserts zeros between the data samples, interpolating the input data stream up to the clock rate. On reset, the part is set to gated mode and the input enables are disabled. The

inputs are enabled by the first global SYNCI signal or SYNCIx signal, where  $X = 0, 1, 2$  or  $3$ .

The input section can select one channel from a multiplexed data stream of up to eight channels. The input enable is delayed by zero to seven clock cycles to enable a selection register. The register following the selection register is enabled by the non-delayed input enable to realign the processing of the channels. The one-clock-wide input enable must align with the data for the first channel. The desired channel is then selected by programming the delay. A delay of zero selects the first channel, a delay of one selects the second, etc.

The parallel input busses are 17 bits wide allowing for up to 16 bits of fixed-point data or 14 bits of mantissa with three bits of exponent for floating-point data. The input format may be twos complement or offset binary format in either fixed or floating

point modes. The floating point modes and the mapping of the parallel 17-bit input format is discussed below.

**Floating Point Input Mode Bit Mapping**

The input bit weighting for fixed point inputs on busses A, B, C, and D is:

bit 15 (MSB):  $2^0$ , bit 14:  $2^{-1}$ , bit 13:  $2^{-2}$ , ..., bit 0:  $2^{-15}$ .

For floating point modes, the least significant two or three bits are used as exponent bits (See *Floating Point Input Mode Bit Mapping Tables*).

The first three floating point modes shown below are included for backward compatibility with the HSP50216 and their functionality remains unchanged. The 14-bit mantissa / 2-bit exponent mode present in the HSP50216 has been extended from a 12dB range to 18dB in the ISL5216. This

mode as well as those which follow it in the tables below use the CIC's barrel shifter to provide the gain. This places a limit on the CIC's largest available decimation. As an example, assume the CIC is set for 5th order and the decimation needs to be 300. The CIC's gain,  $300^5$ , is compensated for in the barrel shifter with a shift factor of  $45 - \text{ceil}(\log_2(300^5)) = 3$  where shifts are from LSB towards MSB and a shift of 45 corresponds to no attenuation. If the shift factor is set as 0 in this example, there is room for  $3 * 6 = 18\text{dB}$  of gain. Raising the CIC decimation lowers the shift factor (to further attenuate the CIC input signal) and limits the available gain range. This CIC decimation / floating point gain range trade off is handled automatically by the evaluation board software. Additional information on the CIC can be found in the CIC Filter section of this data sheet.

**Floating Point Input Mode Bit Mapping Tables**

**11-BIT MODE: 11 TO 13-BIT MANTISSA (15:3), 3-BIT EXPONENT (2:0), 30dB EXPONENT RANGE (Note 3)**

13. To select this mode, set IWA \*000H / GWA F804H bits 17, 16, 8 and 7 to 1, 1, 0 and 1 respectively.

**Level Detector**

An input level detector is provided to monitor the signal level on any of the input busses. The input bus, input format, and the level detection type are programmable (see *Microprocessor Interface* section, GWA registers F804h, F805h and F806h). This signal level represents the wideband signal from the A/D and is useful for controlling gain / attenuation blocks ahead of the converter.

The supported monitoring modes are: integrated magnitude (like the HSP50214 w/o the threshold), leaky integration ( $Y_n = X_n \times A + Y_{n-1} \times (1-A)$  where  $A = 1, 2^{-8}, 2^{-12},$  or  $2^{-16}$  (see GWA = F805h), and peak detection. The measurement interval can be programmed from 2 to 65537 samples (or continuous for the leaky integrator and peak detect cases). The output is 32 bits and is read via the  $\mu$ P interface.

Note that the accumulators in the input level detector are 32 bits wide. This may limit the integration range to as few as 512 samples (for a 42dB exponent range).

FIGURE 1. INTEGRATED MODE

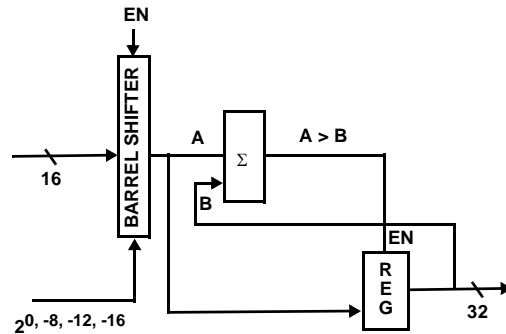

FIGURE 2. PEAK DETECTOR

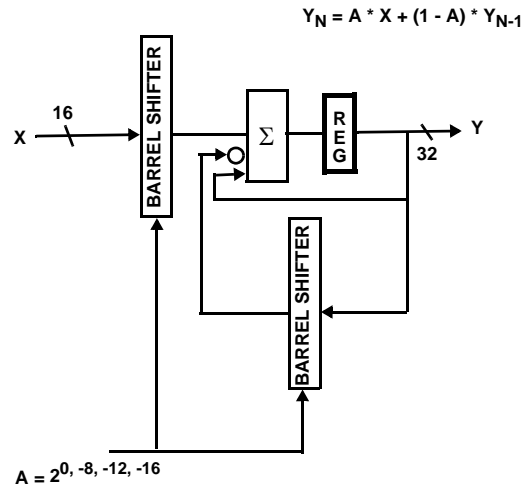

FIGURE 3. LEAKY INTEGRATOR

**Complex Input Mode**

In this mode, complex (I/Q) data can be input using two clock cycles with I input first and Q input second. The  $\overline{EN}_i$  signal indicates the clock cycle when I is valid. The Q data is taken on either the next input clock or two clocks after I, as determined by IWA \*000H bit 23. The complex multiply is done in two clock cycles:  $I * \text{COS}$  and  $I * \text{SIN}$  on the first

clock and Q \* (-SIN) and Q \* COS on the second clock cycle. The first integrator of the CIC is enabled on both clock cycles to add the two products. The rest of the stages are enabled only on the first cycle.

In complex input mode, the input level detector uses only I samples for its magnitude computation.

The CIC decimation counter is programmed for two times the number of complex input samples. The exponent input must be the same for I and Q for the floating point modes.

See IWA \*000h for details on controlling the complex input mode.

**NCO/Mixer**

After the input select/format section, the samples are multiplied by quadrature sine wave samples from the carrier NCO. The NCO has a 32-bit frequency control, providing sub-hertz resolution at the maximum clock rate. The quadrature sinusoids have exceptional purity. The purity of the NCO should not be the determining factor for the receiver dynamic range performance. The phase quantization to the sine/cosine generator is 24 bits and the amplitude quantization is 19 bits.

The carrier NCO center frequency is loaded via the μP bus. The center frequency control is double buffered - the input is loaded into a center frequency holding register via the μP interface. The data is then transferred from the holding register to the active register by a write to a address IWA \*006h or by a SYNCI signal, if loading via SYNCI is enabled. To synchronize multiple channels, the carrier NCO phase accumulator feedback can be zeroed on loading to restart all of the NCOs at the same phase. A serial offset frequency input is also available for each channel through the D(15:0) parallel data input bus (if that bus is not needed for data input). This is legacy support for HSP50210 type tracking signals. See IWA=\*000 and \*004 for carrier offset frequency parameters.

After the mixers, a PN (pseudo noise) signal can be added to the data. This feature is provided for test and to digitally reduce the input sensitivity and adjust the receiver range (sensitivity). The effect is the same as increasing the noise figure of the receiver, reducing its sensitivity and overall dynamic range. For testing, the PN generator provides a wideband signal which may be used to verify the frequency response of a filter. The one bit PN data is scaled by a 16-bit programmable scale factor. The overall range for the PN is 0 to 1/4 full scale (see IWA = \*001h). A gain of 0 disables the PN input. The PN value is formed as:

where S is the sign extension of the 16 bit PN gain register value (IWA = \*001H) times the PN chip value and the 16 X's refer to the PN gain register times the PN chip value.

The minimum, non-zero, PN value is  $2^{-18}$  of full scale (-108dBFS) on each axis (-105dBFS total). For an input noise level of -75dBFS, this allows the SNR to be decreased in steps of 1/8dB or less. The I and Q PN codes are offset in time to decorrelate them. The PN code is selected and enabled in the test control register (F800h). The PN is added to the signal after the mix with the three sign bits aligned with the most significant three bits of the signal, so the maximum level is -12dBFS and the minimum, non-zero level is -108dBFS. The PN code can be  $2^{15}-1$ ,  $2^{23}-1$  or  $2^{15}-1 * 2^{23}-1$ .

**CIC Filter**

Next, the signal is filtered by a cascaded integrator/comb (CIC) filter. A CIC filter is an efficient architecture for decimation filtering. The power or magnitude squared frequency response of the CIC filter is given by:

$$P(f) = \left( \frac{\sin(\pi Mf)}{\sin\left(\frac{\pi f}{R}\right)} \right)^{2N}$$

where

- M = Number of delays (1 for the ISL5216)
- N = Number of stages
- and R = Decimation factor.

The passband frequency response for first (N=1) though fifth (N=5) order CIC filters is plotted in Figure 13. The frequency axis is normalized to  $f_S/R$ , making  $f_S/R = 1$  the CIC output sample rate. Figure 15 shows the frequency response for a 5<sup>th</sup> order filter but extends the frequency axis to  $f_S/R = 3$  (3 times the CIC output sample rate) to show alias rejection for the out of band signals. Figure 14 uses information from Figure 15 to provide the amplitude of the first (strongest) alias as a function of the signal frequency or bandwidth from DC. For example, with a 5<sup>th</sup> order CIC and  $f_S/R = 0.125$  (signal frequency is 1/8 the CIC output rate) Figure 14 shows a first alias level of about -87 dB. Figure 14 is also listed in table form in Table 51 (CIC Passband and Alias Levels).

The CIC filter order is programmable from 0 to 5. The CIC may be bypassed by setting the CIC filter order to 0 (IWA = \*004h bits 13:9 are all set equal to 1) and the CIC barrel shift (IWA = \*004h bits 19:14) to 45 decimal. The CIC output rate must, however, be no more than  $CLK_{max} / 4$  where  $CLK_{max}$  is the maximum clock frequency available on the device (see electrical specifications section).

The integrator bit widths are 69, 62, 53, 44, and 34 for the first<sup>†</sup> through fifth stages, respectively, while the comb bit widths are all 32. The integrators are sized for decimation factors of up to 512 with five stages, 2048 with four stages, 32768 with three stages, and 65536 with one or two stages. Higher decimations in the CIC should be avoided as they will cause integrator overflow. In the ISL5216, the

integrators are slightly oversized to reduce the quantization noise at each stage.

A CIC filter has a gain of  $R^N$ , where R is the decimation factor and N is the number of stages. Because the CIC filter gain can become very large with decimation, an attenuator is provided ahead of the CIC to prevent overflow. The 24 bits of sample data are placed on the low 24 bits of a 69 bit bus (width of the first CIC integrator) for a gain of  $2^{-45}$ . A 48 bit barrel shifter then provides a gain of  $2^0$  to  $2^{47}$  inclusive before passing the data to the CIC. The overall gain in the pre-CIC attenuator can therefore be programmed to be any one of 48 values from  $2^{-45}$  to 4, inclusive (see IWA=\*004, bits 19:14). This shift factor is adjusted to keep the total barrel shifter and CIC filter gain between 0.5 and 1.0. The equation which should be used to compute the necessary shift factor is:

$$\text{Shift Factor} = 45 - \text{Ceiling}(\log_2(R^N)).$$

CIC barrel shifts of greater than 45 will cause MSB bits to be lost. Most of the floating point modes on the ISL5216 make use of the CIC barrel shifter for gain. This limits the maximum usable decimation. In particular, shift factor minus maximum exponent must be greater than or equal to zero. Maximum exponent ranges from 0 to 1, 3, or 7 for 1, 2 and 3 exponent bits, representing up to 6, 18, or 42dB of gain, respectively. See *Floating Point Input Mode* section for details.

## Back End Section

One back-end processing section is provided per channel. Each back end section consists of a filter compute engine, a FIFO/timer for evenly spacing samples (important when implementing interpolation filters and resamplers), an AGC and a cartesian-to-polar coordinate conversion block. A block diagram showing the major functional blocks and data routing is shown above. The data input to the back end section is through the filter compute engine. There are two other inputs to the filter compute engine, they are a data recirculation path for cascading filters and a magnitude and  $d\phi/dt$  feedback path for AM and FM filtering. There are seven outputs from each back end processing section. These are I and Q directly out of the filter compute engine (I2, Q2), I and

Q passed through the FIFO and AGC multipliers (I1, Q1), magnitude (MAG), phase (or  $d\phi/dt$ ), and the AGC gain control value (GAIN). The I2/Q2 outputs are used when cascading back end stages. The routing of signals within the back end processing section is controlled by the filter compute engine. The routing information is embedded in the instruction bit fields used to define the digital filter being implemented in the filter compute engine.

## Filter Compute Engine

The filter compute engine is a dual multiply-accumulator (MAC) data path with a microcoded FIR sequencer. The filter compute engine can implement a single FIR or a set of filters. For example, the filter chain could include two halfband filters, a shaping (matched) filter and a resampling filter, all with different decimations. The following filter types are currently supported by the architecture and microcode:

- Even symmetric with even # of taps decimation filters
- Even symmetric with odd # of taps decimation filters (including HBFs)
- Odd symmetric with even # of taps decimation filters
- Odd symmetric with odd # of taps decimation filters
- Asymmetric decimation filters
- Complex filters
- Interpolation filters (up to interpolate by 4)
- Interpolation halfband filters
- Resampling filters (under resampler NCO control)
- Fixed resampling ratio filter (within the available number of coefficients)
- Quadrature to real filtering (w/  $f_s/4$  up conversion)

The input to the filter compute engine comes from one of three sources—a CIC filter output (which can also be another backend section), the output of the filter compute engine (fed back to the input) or the magnitude and  $d\phi/dt$  fed back from the cartesian-to-polar coordinate converter.

The number and size of the filters in the chain is limited by the number of clock cycles available (determined by the decimation) and by the data and coefficient RAM/ROM resources. The data RAM is 384 words (I/Q pairs) deep. The data addressing is modulo in power-of-2 blocks, so the maximum filter size is 256. The block size and the block starting memory address for each filter is programmable so that the available memory can be used efficiently. The coefficient RAM is 192 words deep. It is half the size of the data memory because filter coefficients are typically symmetric. ROMs are provided with halfband filter coefficients, resampling filter coefficients, and constants. The filter compute engine exploits symmetry where possible so that each MAC can compute two filter taps per clock by doing a pre-add before multiplying. In the case of halfband filters, the zero-valued coefficients are skipped for extra efficiency. There is an overhead of one clock cycle per input sample for each filter in the chain (for writing the data into the data RAM) and (except in special cases) a two clock cycle overhead for the entire chain for program flow control instructions.

The output of the filter compute engine is routed through a FIFO in the main output path. The FIFO is provided to more evenly space the FIR outputs when they are produced in bursts (as when computing resampling or interpolation filters). The FIFO is four samples deep. The FIFO is loaded by the output of the filter when that path is selected. It is unloaded by a counter. The spacing of the output samples is specified in clock periods. The spacing can be set from 1 (fall through) to 4096 samples

(approximately the spacing for a 16KSPS output sample rate when using 65MSPS clock) using IWA = \*00Ah bits 11:0.

The number and order of the filtering in the filter chain is defined by a FIR control program. The FIR control program is a sequence of up to 32 instruction words. Each instruction word can be a filter or program flow instruction. The filter instruction defines a FIR in the chain, specifying the type of FIR, number of taps, decimation, memory allocation, etc. For program flow, a wait for input sample(s) instruction, a loop counter load, and several jumps (conditional and unconditional) are provided. The ISL5216 evaluation board includes software for automatically generating FIR control programs for most filter requirements. Examples of programs FIR control programs are given below.

The simplest filter program computes a single filter. It has three instructions (see Sample Filter #1 Program Instructions below):

**SAMPLE FILTER #1 PROGRAM**

STEP	INSTRUCTION
0	Wait for enough input samples (equal to the decimation factor)
1	FIR Type = even symmetric 95 taps Decimate by 2 Compute one output Decrement wait counter Memory block size 128 Memory block start at 64, Coefficient block start at 64 Step size 1 Output to AGC
2	Jump, Unconditional, to step 0

The parameters of the FIR (including type, number of taps, decimation and memory usage) are specified in the bit fields of the step 1 instruction word. To change the filtering the only other change needed is the number of samples in the wait threshold register (IWA = \*00C, bits 9:0). The filter in this example requires 52 clock cycles to compute, allocated as follows:

**SAMPLE FILTER #1 CLOCK CYCLES CALCULATION**

CLOCK CYCLES	FUNCTION PERFORMED
48	Clocks for FIR computation (two taps/clock due to symmetry)
2	Clocks for writing the input data into the data RAMs (Decimate by 2 requires 2 inputs per output)
2	Clocks for the program flow instructions (wait and jump)
52	Total

Using a 65MSPS clock, the output sample rate could be as high as 65MSPS / 52 clocks = 1.25MSPS. The input sample rate to the FIR from the CIC filter would be 2.5MSPS. The impulse response length would be 38µs (95 taps at 0.4µs/tap).

Each additional filter added to the signal processing chain requires one instruction step. As an example of this, a typical filter chain might consist of two decimate-by-2 halfband filters being followed by a shaping filter with the final filter being a resampling filter. The program for this case might be (see Sample Filter Program #2 Instructions below):

**SAMPLE FILTER #2 PROGRAM**

STEP	INSTRUCTION
0	Wait for enough input samples (usually equal to the total decimation—8 in this case)
1	FIR Type = even symmetry 15 taps Halfband Decimate by 2 Compute four outputs Memory block size 32 Memory block start at 0 Coefficient block start at 13 Output to step 2 Decrement wait count
2	FIR Type = even symmetry 23 taps Halfband Decimate by 2 Compute two outputs Memory block size 32 Memory block start at 32 Coefficient block start at 24 Output to step 3
3	FIR Type = even symmetry 95 taps Decimate by 2 Compute one output Memory block size 128 Memory block start at 64 Coefficient block start at 64 Step size 1 Output to step 4
4	FIR Type = resampler Increment NCO 6 taps Compute one output Memory block size 8 Memory block starts at 192 Coefficient block start at 512 Step size 32 Output to AGC
5	Jump, Unconditional, to 0

Sample filter #2 requires:

- 32 + 32 + 128 + 8 = 200 data RAM locations
- (95+1)/2=48 coefficient RAM location (resampler and HBF coefficients are in ROM).

The number of clock cycles required to compute an output for Sample filter #2 is calculated as follows:

**SAMPLE FILTER #2 CLOCK CYCLES CALCULATION**

CLOCK CYCLES	FUNCTION PERFORMED
20	Halfband 1 compute clocks (5 per compute x 4 computes)
8	Halfband 1 input sample writes (8 input samples)
14	Halfband 2 compute clocks (7 per compute x 2 computes)
4	Halfband 2 input sample writes (4 input samples)
48	95 tap symmetric FIR, 2 clocks per tap
2	FIR input sample writes (2 input samples)
6	Resampler (6 taps, nonsymmetric)
1	Resampler input sample write (1 input samples)
1	Jump instruction
1	Wait instruction
105	Clock cycles per output

Total decimation is 8, so the input sample rate for the FIR chain (CIC output rate) could be up to:

$$f_{CLK}/(\text{ceil}(105/8)) = f_{CLK}/14.$$

With a 65MHz clock, this would support a maximum input sample rate to the FIR processor of 4.6MHz and an output sample rate up to 0.580MHz. The shaping filter impulse response length would be:

$$(95 \times 2)/580,000 = 82\mu s.$$

The maximum output sample rate is dependent on the length and number of FIRs and their decimation factors.

Illustrating this concept with Filter Example #3, a higher speed filter chain might be comprised of one 19 tap decimate-by-2 halfband filter followed by a 30 tap shaping FIR filter with no decimation. The program for this example could be:

**SAMPLE FILTER #3 PROGRAM**

STEP	INSTRUCTION
0	Wait for enough input samples (2 in this case)
1	FIR Type = even symmetry 19 taps Halfband Decimate by 2 Compute one output Memory block size 32 Memory block start at 0 Coefficient block start at 18 Output to step 2 Reset wait count
2	FIR Type = even symmetry 30 taps Decimate by 1 Compute one output Memory block size 64 Memory block start at 32 Coefficient block start at 64 Step size 1 Output to AGC
3	Jump, Unconditional, to 0

The number of clock cycles required to compute an output for Sample filter #3 is calculated as follows:

**SAMPLE FILTER #3 CLOCK CYCLES CALCULATION**

CLOCK CYCLES	FUNCTION PERFORMED
6	19 tap halfband, one output
2	halfband input writes (2 input samples)
15	30 tap symmetric FIR, 2 taps per clock
1	1 FIR input write
1	1 wait
1	1 jump
26	Clock cycles per output

For Filter Example #3 and a 65MSPS input, the maximum FIR input rate would be 65MSPS / ceil(26 / 2) = 5MSPS giving a decimate-by-2 output sample rate of 2.5MSPS. At 80MSPS, the FIR could have up to 42 taps with the same output rate.

Channels 0, 1, 2 and 3 can be combined in a polyphase structure for increased bandwidth or improved filtering.

Filter Example #4 will be used to demonstrate this capability.

Symbol rate of 4.096 MSym. The desired output sample rate is 8.192MSPS. Arrange the four back end sections as four filters operating on the same CIC output at a rate of

65.536MHz/4=16.384MHz, where the factor of 4 is the CIC decimation we have chosen.

Each channel computes the same sequence, offset by one output sample from the previous sample (see IWA = \*00Bh). Each channel decimates down to 2.048M and then the channels are multiplexed together in the output formatter to get the desired 8.192MSPS. The input sample rate to the final filter of each channel must meet Nyquist requirements for the final output to assure that no information is lost due to aliasing.

**SAMPLE FILTER #4 PROGRAM**

STEP	INSTRUCTION
0	Wait for enough input samples (8 in this case)
1	FIR type = even symmetry 44 taps decimate by 8 compute one output memory block size 64 memory block start at 0 coefficient block start at 64 step size 1 output to AGC offset memory read pointers by 0, -2, -4, -6
2	Jump, Unconditional, to 0

The number of FIR taps available for these requirements is calculated as follows:

$$65536/2048 = 32 \text{ clocks}$$

$$\text{minus } (8 \text{ writes} + 1 \text{ wait} + 1 \text{ jump} = 10 \text{ clocks})$$

$$= 22 \text{ clocks}$$

Therefore, the number of taps available is:

$$22 \times 2 = 44 \text{ taps.}$$

Multiplexing the four outputs gives a final output sample rate of 8.192MSPS.

The impulse response is 44 taps at 16.384M or 22 output samples (11 symbols at 4.096M).

The AGC loop filter output of channel 4 can be routed to control the forward AGC gain control of all four channels. This assures that the gains of the four back end sections are the same. The gain error, however, is only computed from every fourth output sample.

The back end processing sections of two or more ISL5216s can be combined using the same polyphase approach, but the AGC gain from one part cannot be shared with another part (except via the  $\mu$ P interface), so polyphase filter using multiple parts would typically usually use a fixed gain.

The filter sequencer is programmed via an instruction RAM and several control registers. These are described below.

### Instruction RAMs

The filter compute engine is controlled by a simple sequencer supporting up to 32 steps. Each step can be a filter or one of four sequence flow instructions—wait, jump (conditional or unconditional), load loop counter, or NOP. There are 128 bits per instruction word with each word consisting of condition code selects, FIR parameters and data routing controls. Not all of the instruction word bits are used for all instruction types. The actual sequencer instruction is only 9 bits. The rest of the bits are used for filter parameters or for the loop counter preload. Each sequence step is loaded by the microprocessor in four 32-bit writes. The mapping of the bit fields for the instruction types is shown in the instruction bit field table that follows. These FIR instruction words can be generated using software tools provided with the ISL5216 evaluation board.

When the filter is reset, the instruction pointer is set to 31 (the last instruction step). The read and write pointers are initialized on reset, so a reset must be done when the channel is initialized or restarted.

A fixed offset can be added to the starting read address of one of the filters in the program. This function is provided to offset the data reads of the filters in a polyphase filter bank; all filters in the bank will write the same data to the same RAM location. To offset the computations the RAM read address is offset. See IWA = \*00Bh for details.

The instruction word bits (127:0) are assigned to memory words as follows:

31:0 to destination C C C C 0 0 0 1 0 x x x x 0 0

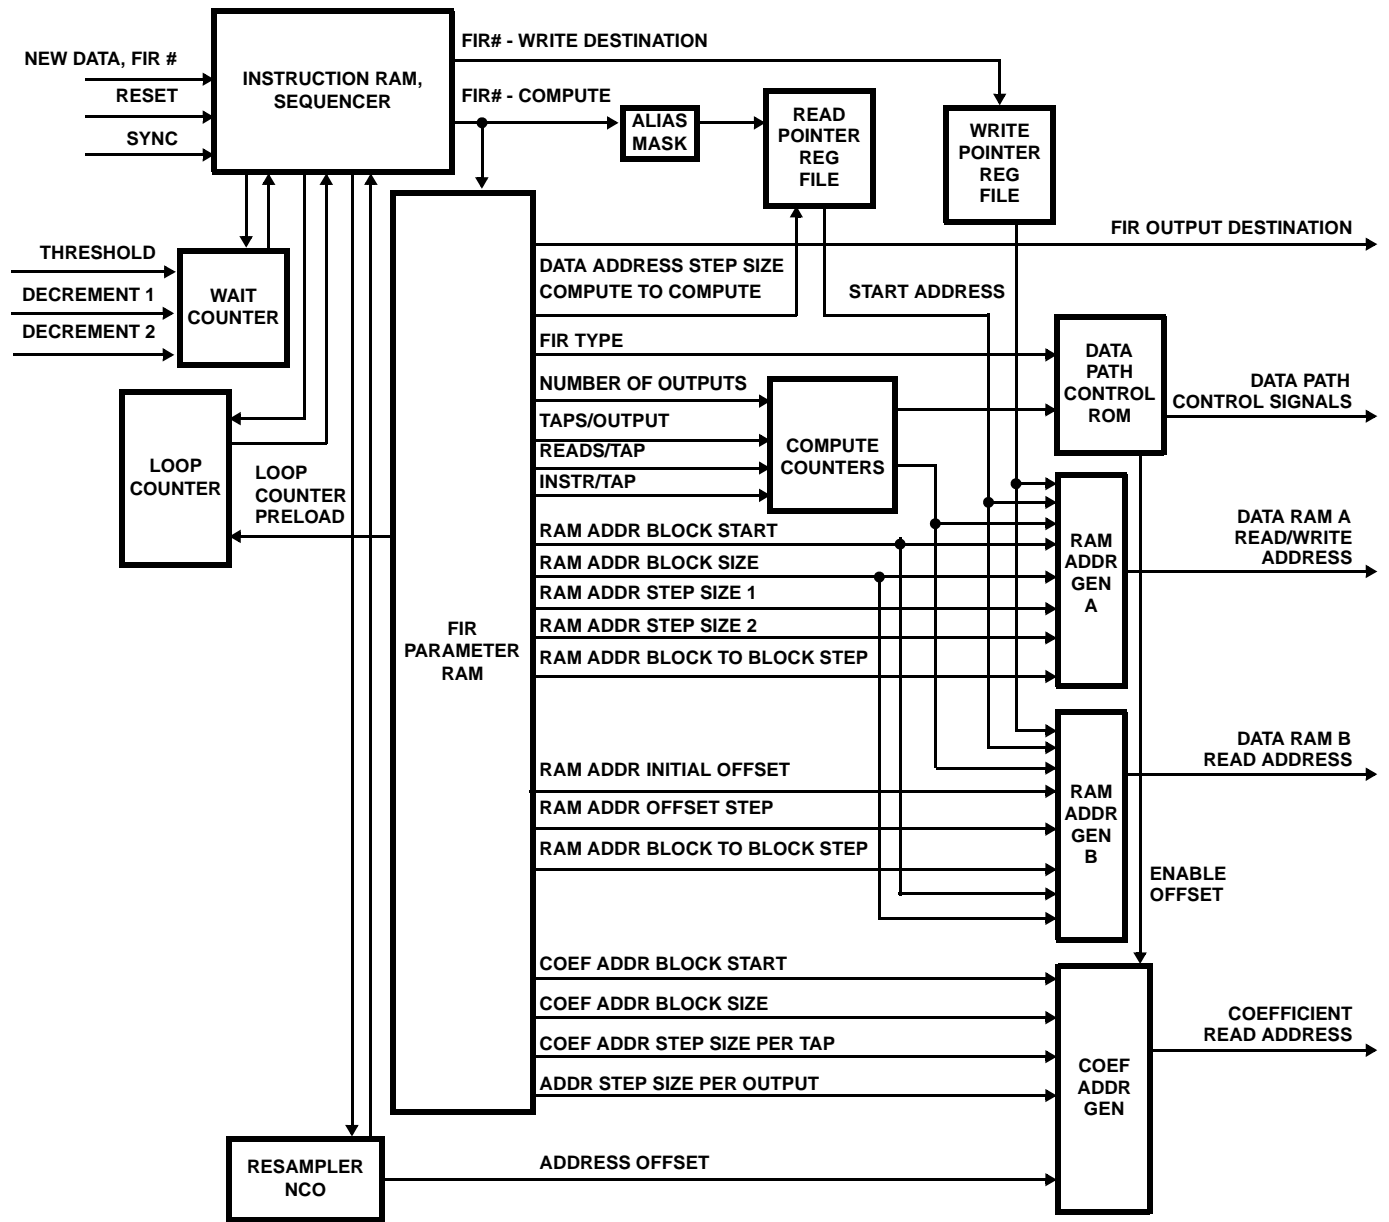

63:32 to destination C C C C 0 0 0 1 0 x x x x 0 1

95:64 to destination C C C C 0 0 0 1 0 x x x x 1 0

**Basic Instruction Set Examples**

- Wait for number of input samples  $\geq$  threshold  
127:9 = 0  
8:0 = 001  
0000,0000,0000,0001h
- Jump unconditional  
127:9 = 0  
8:0 = 1JJJJ111b  
example: jump to step 0= 0000,0000,0000,0107h
- Jump RSCO (jump on resampler NCO carry output)  
127:9 = 0  
8:0 = 1JJJJ101b  
example: jump RSCO, step 0= 0000,0000,0000,0105h
- Jump  $\overline{\text{RSCO}}$  (jump on no resampler NCO carry output)  
127:9 = 0

- 8:0 = 1JJJJ100b  
example: jump  $\overline{\text{RSCO}}$ , step 0 = 0000,0000,0000,0104h
- NOP single clock  
127:9 = 0  
8:0 = 010000000b  
NOP1 = 0000,0000,0000,0080h
- Load Loop Counter  
127:21 = 0  
20:9 = Loop counter preload (tested against 0)  
8:0 = 010000100b  
example: LdLpCntr 14 = 0000,0000,0000,1C84h

**Single FIR Basic Program**

This is the basic program for a single FIR. This program applies to decimation filters (including DECx1) that are symmetric or asymmetric (but not complex). The FIR output is routed through path A with the AGC enabled.

**0 - WAIT FOR ENOUGH SAMPLES**

```

0000 0000 0000 0000 0000 0000 0000 0000 127:96 00000000h
0000 0000 0000 0000 0000 0000 0000 0000 95:64 00000000h
0000 0000 0000 0000 0000 0000 0000 0000 64:32 00000000h
0000 0000 0000 0000 0000 0000 0000 0001 31:0 00000001h
    
```

**1 - FIR**

```

0000 0001 0101 1111 1111 100R RRRR RRRR 127:96 015FF---h
00TT TTTT TTTD DDDD DDDD 0000 0000 0111 95:64 -----007h
0000 1000 0000 0000 0000 1010 0000 0000 63:32 08000A00h
0000 1011 0000 0000 0FFF FFF0 1100 1000 31:0 0B00--C8h
    
```

**2 - JUMP TO STEP 0**

```

0000 0000 0000 0000 0000 0000 0000 0000 127:96 00000000h
0000 0000 0000 0000 0000 0000 0000 0000 95:64 00000000h
0000 0000 0000 0000 0000 0000 0000 0000 64:32 00000000h
0000 0000 0000 0000 0000 0001 0000 0111 31:0 00000107h
    
```

Four bit fields must be filled in:

- F - filter type (this example applies to types 1-5)
- D - decimation (also loaded into wait threshold)
- T - number of taps minus 1
- R - clocks/calculation (=floor((taps+1)/2) for symmetric, = taps for asymmetric)

The rest of the instruction RAM would typically be filled with NOP instructions:

```

0000 0000 0000 0000 0000 0000 0000 0000 127:96 00000000h
0000 0000 0000 0000 0000 0000 0000 0000 95:64 00000000h
0000 0000 0000 0000 0000 0000 0000 0000 64:32 00000000h
0000 0000 0000 0000 0000 0000 1000 0000 31:0 00000080h
    
```

### Wait Preload Register

This register (IWA register \*00Ch) holds the wait counter threshold and two wait counter decrement values. Each is ten bits. The wait counter counts filter input samples until the count is greater than or equal to the threshold. The wait counter then asserts a flag to the filter compute engine.

The wait counter threshold is typically set to the total number of input samples needed to generate a filter output. A "WAIT" instruction in the filter compute engine waits for the wait counter flag signal before proceeding. The filter compute engine would then compute all the filters needed to produce an output and then would jump back to the "WAIT" instruction.

The wait counter is implemented with an accumulator. This allows the count to go beyond the threshold without losing the sample count. Two bits in the FIR instruction decrement the wait counter (subtract a value) and select the decrement value. The decrement value is typically the number of samples needed for an output (total decimation), though it can be a different value to ignore inputs and shift the timing. (The read pointer increment must be adjusted as well.)

The filter compute engine sequencer does not count each input sample or track whether each filter is ready to run. Instead, the wait counter is used to determine whether there are enough input samples to compute all the filters in the chain and get an output sample from the entire filter chain. This adds some additional delay since intermediate results are not precalculated, but it simplifies the filter control. The number of samples needed is equal to the total decimation of the filter chain. For example, with two decimate-by-2 halfband filters and a decimate-by-2 shaping FIR, the total decimation would be 8 so 8 samples are needed to compute an output. HBF1 would compute four times to generate four inputs to HBF2. HBF2 would compute twice to generate the two samples that the shaping FIR needs to compute an output.

### Resampler

The resampler is an NCO controlled polyphase filter that allows the output sample rate to have a non-integer relationship to the input sample rate. The filter engine can be viewed conceptually as a fixed interpolate-by-32 filter, followed by an NCO controlled decimator. The Resampler NCO is similar to the carrier NCO phase accumulator but does not include the SIN/COS section. It provides the resampler output pulse and associated phase information to logic that determines the nearest of the 32 available phase points for a given output sample.

The center frequency (output sample rate) control is double buffered, i.e., the control word is written to one register via the microprocessor interface and then transferred to another (active) register on a write to the timing NCO center frequency update strobe location (IWA register \*009h) or on a SYNCI (if enabled). As it is not possible to represent some frequencies

exactly with an NCO and therefore, phase error accumulates eventually causing a bit slip, the phase accumulator length has been sized to where the error is insignificant. At a resampler input rate of 1MHz, half an LSB of error in loading the 56-bit accumulator is  $7 \cdot 10^{-12}$  degrees. After one year, the accumulated phase error is only  $0.2 \cdot 10^{-3}$  of a bit ( $< 1/10$  of a degree). The NCO update by the filter compute engine is typically at the resampler's input rate, and is enabled by the IncrRS bit in the filter instruction word. The NCO then rolls over at a fraction of the resampler input rate. The output sample rate is  $(f_{IN} / 2^{56}) \cdot N$ , where  $f_{IN}$  is the resampler input rate and N is the phase accumulated per resampler input sample (IWA registers \*007h and \*008h). N must be between 4000000000000h and FFFFFFFFh corresponding to decimations from 4 to  $(1 + 2^{-56})$ , respectively. Generally, however, a range of 8000000000000h to FFFFFFFFh (providing decimation from 2 to  $(1 + 2^{-56})$ , respectively) is sufficient for most applications since integer decimation can be done more efficiently in the preceding CIC and halfband filters. The resampler changes the sample rate by computing an output at each input which causes the NCO to roll over. If an output is to be computed, the nearest of the 32 available points from the polyphase structure is used. Because outputs are generated only on input samples which cause an NCO roll over, output samples will in general not be evenly spaced. The FIFO/TIMER block between the filter compute engine and the AGC is provided to improve output sample spacing for presentation to the serial data output formatter section (see IWA=\*00Ah bits 11:0 description). If D/A converted directly, there would be artifacts from the uneven sample spacing, but if the samples are stored and reconstructed at the proper rate (the NCO rollover rate), the signal would have only the distortion produced by interpolation image leakage and the time quantization (phase jitter) due to the finite number of interpolation filter phases.

The polyphase filter has 192 coefficients implemented as 32 phases, each of which having 6 taps ( $6 \times 32 = 192$ ). These coefficients are provided in Table 54. The stopband attenuation of the filter is greater than 60dB, as shown in Figures 18–20. The signal to total image power ratio is approximately 55dB, due to the aliasing of the interpolation images. If the output is at least 2x the baud rate, the 32 interpolation phases yield an effective sample rate of 64x the baud rate or approximately 1.5% (1/64 resampler input sample period) maximum timing error.

### AGC

The AGC Section provides gain to small signals, after the large signals and out-of-band noise have been filtered out, to ensure that small signals have sufficient bit resolution in the output formatter. The AGC can also be used to manually set the gain. The AGC optimizes the bit resolution for a variety of input amplitude signal levels. The AGC loop automatically adds gain to bring small signals from the lower bits of the

24-bit programmable FIR filter output into the range of 20-bit and shorter words in the output section. Without gain control, a signal at -72dBFS =  $20\log_{10}(2^{-12})$  at the input would have only 4 bits of resolution at the output if a 16 bit word length were to be used (12 bits less than the full scale 16 bits). The potential increase in the bit resolution due to processing gain of the filters can be lost without the use of the AGC.

Figure 4 shows the Block Diagram for the AGC Section. The FIR filter data output is routed to the Cartesian to polar coordinate converter after passing through the AGC multipliers and shift registers. The magnitude output of the Cartesian to polar coordinate converter is routed through the AGC error detector, the AGC error scaler and into the AGC loop filter. This filtered error term is used to drive the AGC multiplier and shifters, completing the AGC control loop.

The AGC multiplier / shifter portion of the AGC is identified in Figure 4. The gain control from the AGC loop filter is

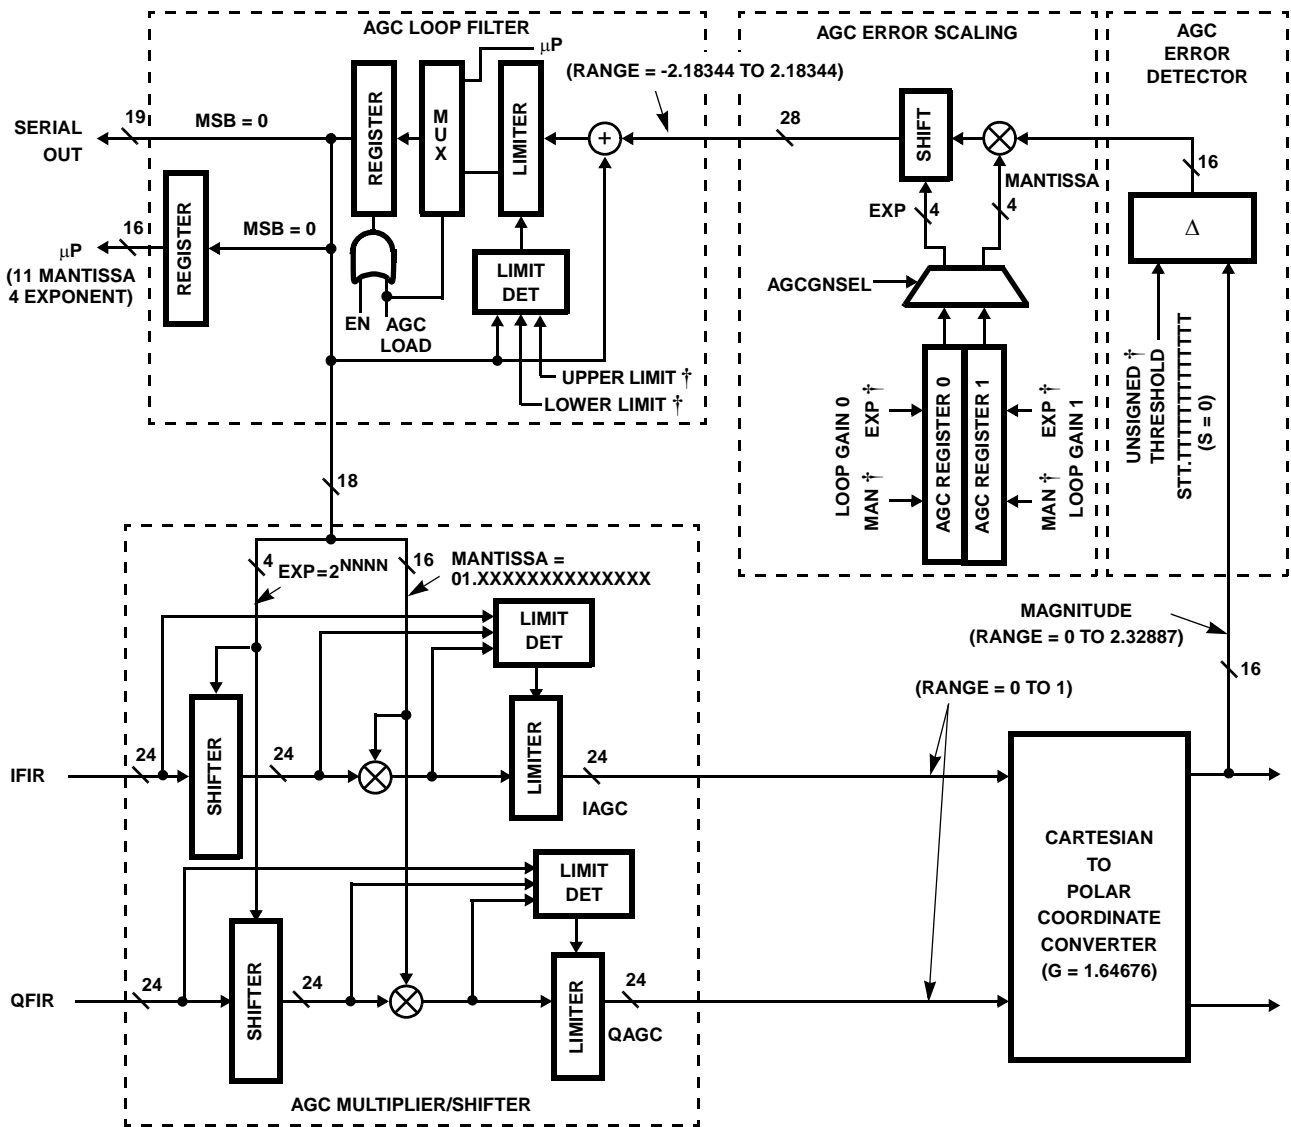

sampled when new data enters the multiplier / shifter. The limit detector detects overflow in the shifter or the multiplier and saturates the output of I and Q data paths independently. The shifter has a gain from 0 to 90.31dB in 6.021dB steps, where  $90.31\text{dB} = 20\log_{10}(2^N)$  when  $N = 15$ . The mantissa provides up to an additional 6.02dB gain. The gain in dB from the mantissa is:

$20\log_{10}[1+(X)2^{-14}]$ , where X is the fractional part of the mantissa interpreted as an unsigned integer ranging from 0 to  $2^{14} - 1$ .

Thus, the AGC multiplier / shifter transfer function is expressed as:

$$\text{AGC Mult/Shift Gain} = 2^N [1 + (X)2^{-14}]$$

where N, the shifter exponent, has a range of  $0 < N < 15$  and X, the mantissa, has a range of  $0 < X < (2^{14} - 1)$ .

† Controlled via microprocessor interface.

FIGURE 4. AGC FUNCTIONAL BLOCK DIAGRAM

The loop gain mantissas and exponents are set in IWA register \*010h, with IWA register \*013h selecting loop gain 0 or 1 and the settling mode.

In the ISL5216, a SYNCI signal will clear the AGC loop filter accumulator if GWA register F802h bit 27 is set. This sets the AGC to unity gain or to the lower gain limit (IWA \*011h bits 15:0) if it is larger than unity.

The settling mode of the AGC forces either the mean or the median of the signal magnitude error to zero, as selected by IWA register \*013h bit 8. For mean mode, the gain error is scaled and used to adjust the gain up or down. This proportional scaling mode causes the AGC to settle to the final gain value asymptotically. This AGC settling mode is preferred in many applications because the loop gain adjustments get smaller and smaller as the loop settles, reducing any AM distortion caused by the AGC.

With this AGC settling mode, the proportional gain error causes the loop to settle more slowly if the threshold is small. This is because the maximum value of the threshold minus the magnitude is smaller. Also, the settling can be asymmetric, where the loop may settle faster for “over range” signals than for “under range” signals (or vice versa).

In some applications, such as burst signals or TDMA signals, a very fast settling time and/or a more predictable settling time is desired. The AGC may be turned off or slowed down after an initial AGC settling period.

The median mode minimizes the settling time. This mode uses a fixed gain adjustment with only the direction of the adjustment controlled by the gain error. This makes the settling time independent of the signal level.

For example, if the loop is set to adjust 0.5dB per output sample, the loop gain can slew up or down by 16dB in 16 symbol times, assuming a 2-samples-per-symbol output sample rate. This is called a median settling mode because the loop settles to where there is an equal number of magnitude samples above and below the threshold. The disadvantage of this mode is that the loop will have a wander (dither) equal to the programmed step size. For this reason, it is advisable to set one loop gain for fast settling at the beginning of the burst and the second loop gain for small adjustments during tracking.

In the median mode, the maximum gain step is approximately 3dB / output. The step is fixed (it does not decrease as the error decreases) so a large gain will cause AM on the output at least that large. The fixed gain step is set by the programmable AGC loop gain register IWA \*010h.

The AGC gain limits register sets the minimum and maximum limits on the AGC gain. The total AGC gain range is 96dB, but only a portion of the range should be needed for most applications. For example, with a 16-bit output to a processor, the 16 bits may be sufficient for all but 24dB of the total input range possible. The AGC would only need to have a range of 24dB. This allows faster settling and the AGC would be at its maximum gain limit except when a high power signal was received. The AGC may be disabled by setting both limits to the same value.

The median settling mode is enabled by setting IWA register \*013h bit 8 to 0 while the mean loop settling mode is selected by setting bit 8 to 1.

### Cartesian to Polar Converter

The Cartesian to Polar converter computes the magnitude and phase of the I/Q vector. The I and Q inputs are 24 bits wide. The converter phase output is 18 bits wide and is routed to the output formatter and frequency discriminator. This 18-bit output phase can be interpreted either as two's complement (-0.5 to approximately 0.5) or unsigned (0.0 to approximately 1.0), as shown in Figure 5. The phase conversion gain is  $1/2\pi$ . The 24-bit magnitude is unsigned binary format with a range from 0 to 2.32. The magnitude conversion gain is 1.64676. The MSB of the magnitude (the sign bit) is always zero.

FIGURE 5. PHASE BIT MAPPING OF COORDINATE CONVERTER OUTPUT

Table 1 details the phase and magnitude weighting for the 16 bits output from the PDC.

**TABLE 1. MAG/PHASE BIT WEIGHTING**

BIT	MAGNITUDE	PHASE (°)

1	$2^{-20}$	0.00004283722
0 (LSB)	$2^{-21}$	0.00002141861

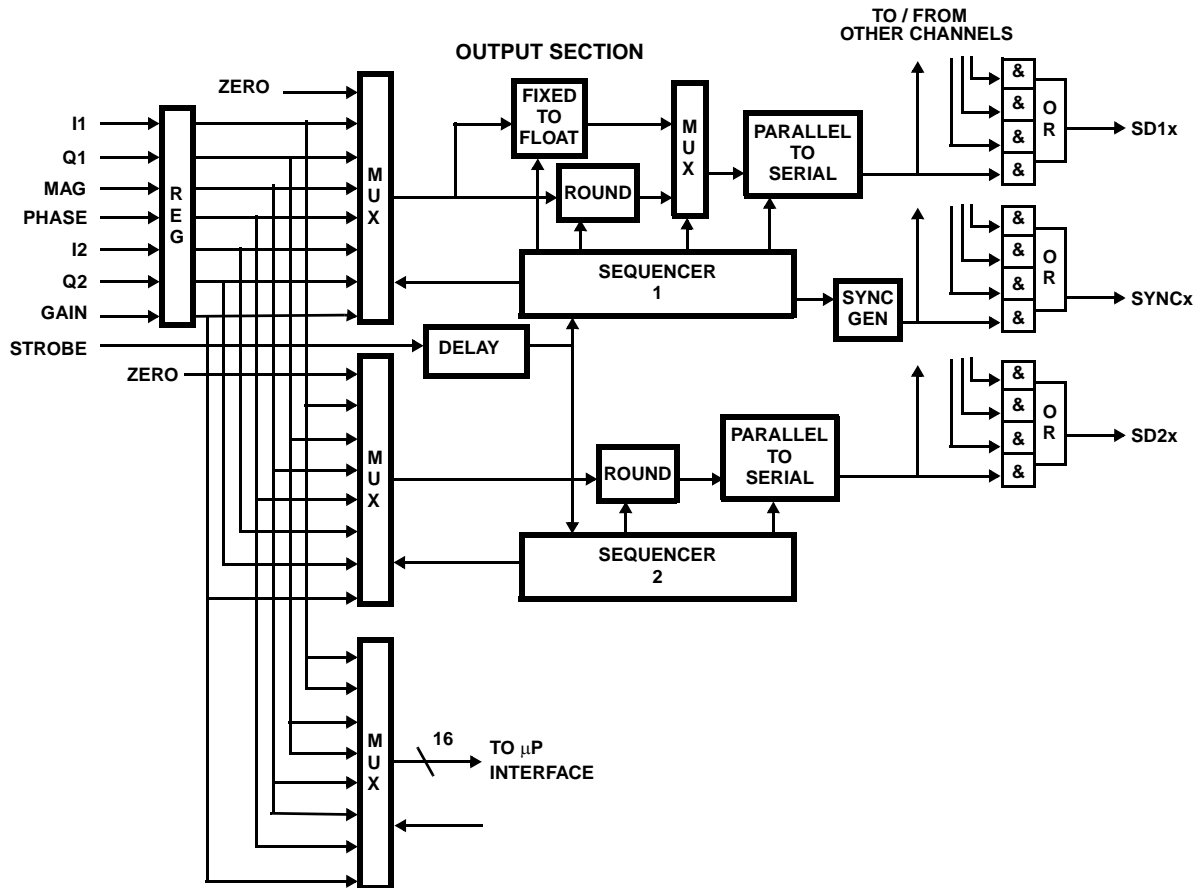

The magnitude and phase computation requires 17 clocks for full precision. At the end of the 17 clocks, the magnitude and phase are latched into a register to be held for the next stage, either the output formatter or frequency discriminator. If a new input sample arrives before the end of the 17 cycles, the results of the computations up until that time, are latched. This latching means that an increase in speed causes only a decrease in accuracy. Table 2 details the exact accuracy that can be obtained with a fixed number of clock cycles up to the maximum of 17. The input magnitude and phase errors induced by normal SNR values will almost always be worse than the Cartesian to Polar conversion.

**TABLE 2. MAG/PHASE ACCURACY vs CLOCK CYCLES**

CLOCKS	MAGNITUDE ERROR (% $f_S$ )	PHASE ERROR (DEG.)†	PHASE ERROR (% $f_S$ )
6	0.065	3.5	2

† Assumes  $\pm 180^\circ = f_S$ .

## Serial Data Output Formatter Section

NOTE: Each serial output has 7 time slots. Each slot can contain I1, Q1, I2, Q2, Mag, phase or  $d\phi/dt$ , AGC gain, or zeros. Each slot can be 4, 6, 8, 10, 12, 16, 20, 24, or 32 (24 + 8 zeros) bits or disabled. Output 1 can also be 32-bit floating point. Slots can be disabled. A disabled slot will be one clock wide if there are other active slots following. A sync can be asserted with any or all slots in output 1. The serial output can be delayed from 0 to 4095 serial clock periods from the input strobe. The serial outputs are always MSB first. The sync position applies to all time slots and can be one clock prior to the first data bit, aligned with the first data bit, or one clock after the last data bit.

### Serial Data Output Control Register

The serial data output control register contains sync position and polarity (SYNCA, B, C or D), channel multiplexing, and scaling controls for the SD1x and SD2x (x = A, B, C or D) serial outputs (see Microprocessor Interface Section, IWA register \*014h).

### Channel Routing Mask

The multiplexing mask bits for each channel (see Microprocessor Interface Section, IWA register \*014h bits 19:16 for SD1x or bits 15:12 for SD2x) can be used to enable that channel's output to any of the four serial outputs. These bits control the AND gates that mask off the channels, so a zero disables the channel's connection to that output.

To configure more than one channel's output onto a serial data output, the SD1 serial outputs and syncs from each channel (0, 1, 2 and 3) are brought to each of the SD1 serial output sections and the SD2 serial outputs are brought to

each of the SD2 serial output sections (the syncs are only associated with the SD1 serial outputs). There, the four outputs are AND-ed with the multiplexing mask programmed in the serial data output control registers of channels 0 thru 3 and OR-ed together. By gating off the channels that are not wanted and delaying the data from each desired channel appropriately, the channels can be multiplexed into a common serial output stream. It should be noted that in order to multiplex multiple channels onto a single serial data stream the channels to be multiplexed must be synchronous.

### Serial Data Output Time Slot Content/Format Registers

These four registers are used to program the content and format of the serial data output sequence time slots (see Microprocessor Interface Section, IWA registers \*015h - \*018h). There are seven data time slots that make up a serial data output stream. The number of data bits and data format

of each slot is programmable as well as whether there will be a sync generated with the time slot (the syncs are only associated with the SD1 serial outputs). Any of seven types of data or zeros can be chosen for each time slot. Eight bits are used to specify the content and format of each slot.

As an example, suppose we wanted to output 32-bit I and Q values from channels 0 and 1 into the SD1A serial data output stream, we would program the following settings in the channel's serial data output control and content/format registers:

Channel 0:

delay = 0 (IWA = 0014h, bits 11:0 = 0);

first data time slot = I, 32-bit, sync pulse generated (IWA = 0015h, bits 7:0 = 0xC9);

second data time slot = Q, 32-bit, no sync pulse (IWA = 0015h, bits 15:8 = 0x4A);

third through seventh data time slot = zero and no sync, (IWA = 0015h, bits 31:16 = 0 and IWA = 0016h, bits 31:0 = 0);

enable the SD1A serial output for this channel in the serial routing mask (IWA = 0014h, bit 16 = 1).

Channel 1:

delay = 64 (IWA = 1014h, bits 11:0 = 0x40);

first data time slot = I, 32-bit, sync pulse generated (IWA = 1015h, bits 7:0 = 0xC9);

second data time slot = Q, 32-bit, no sync pulse (IWA = 1015h, bits 15:8 = 0x4A);

third through seventh data time slot = zero and no sync, (IWA = 1015h, bits 31:16 = 0 and IWA = 1016h, bits 31:0 = 0);

enable the SD1A serial output for this channel in the serial routing mask (IWA = 1014h, bit 16 = 1).

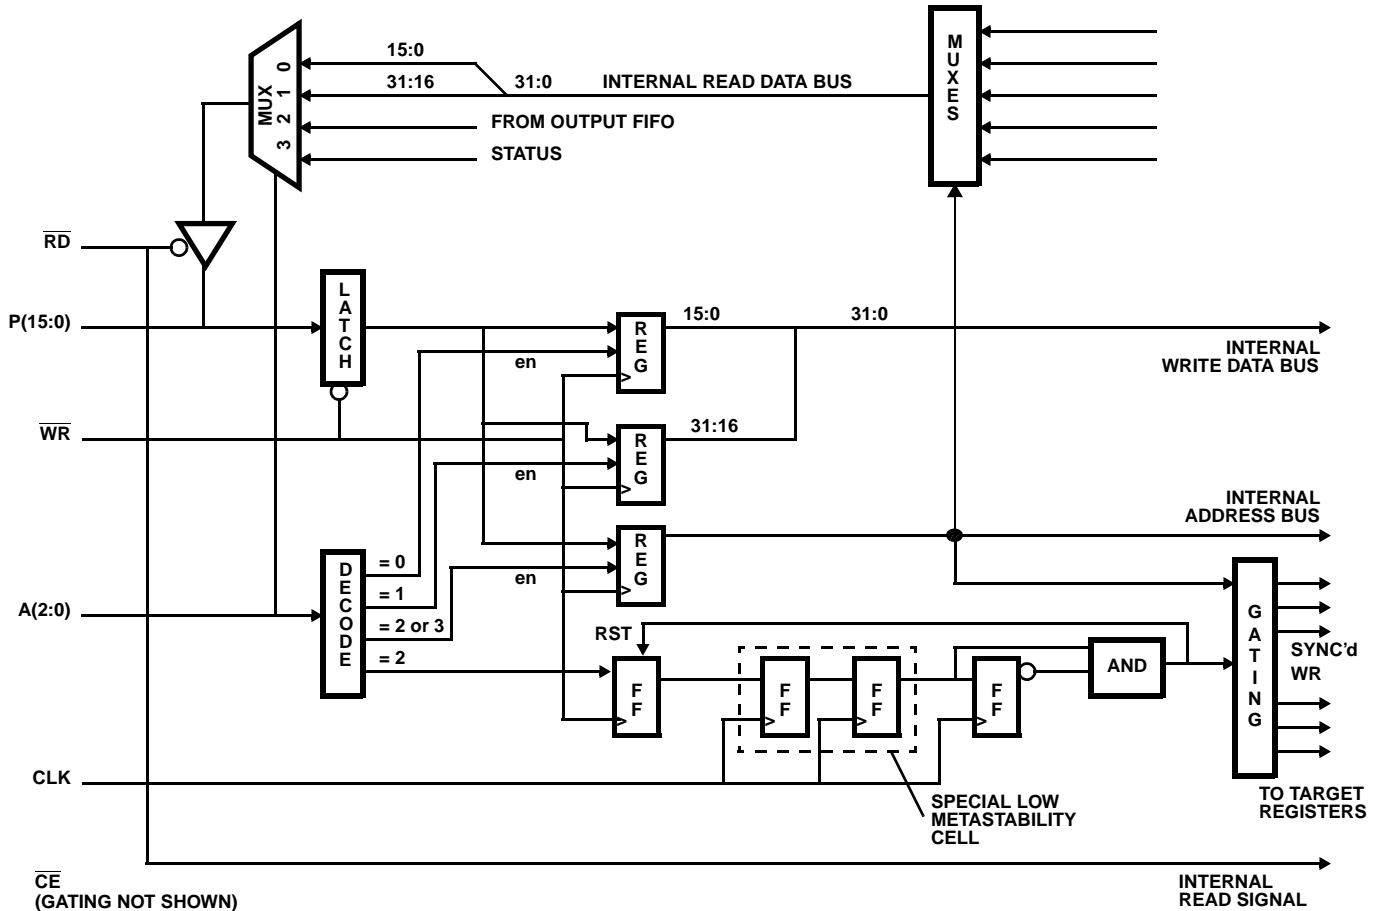

The resulting order is CH0 I first, then CH0 Q, CH1 I, and CH1 Q with sync pulses generated in the I data slots. The position of the sync pulses relative to the data slot may be programmed with IWA register \*014h bits 25:24.

Setting delay = 64 offsets channel 1's 32-bit I and Q data by 64 clocks so that it immediately follows the 64 bits of data from channel 0. In this way channel 1's first and second time slots follow channel 0's second time slot.

Instead of using the delay to offset channel 1's data, channel 0 could have been configured to output 32 bits of I in the first slot, 32 bits of Q in the second slot, 32 bits of zeros in the third slot and 32 bits of zeros in the fourth slot. Channel 1 could then be configured to output 32 bits of zeros in the first and second slots, 32 bits of I in the third slot and 32 bits of Q in the fourth slot. As the channel outputs are OR'd together, the zero slots do not interfere with data slots.

The ISL5216 Microprocessor ( $\mu$ P) interface consists of a 16-bit bidirectional data bus, P(15:0), three address pins, ADD(2:0), a write strobe ( $\overline{WR}$ ), a read strobe ( $\overline{RD}$ ) and a chip enable ( $\overline{CE}$ ). Indirect addressing is used for control and configuration of the ISL5216. The control and configuration data to be loaded is first written to a 32-bit holding register at direct (external) addresses ADD(2:0) = 0 and 1, 16 bits at a time. The data is then transferred to the target register, synchronous to the clock, by writing the indirect (internal) address of the target register to direct (external) address 2, ADD(2:0) = 2. The interface generates a synchronous one clock cycle wide strobe to transfer the data contained in the holding register to the target register. The synchronization and write process requires four clock periods. New data **should not** be written to the holding register until after the synchronization period is over.

## Microprocessor Interface

Data reads can be direct, indirect or FIFO-like depending on the data that is being read. The status register is read directly at direct (external) address 3,  $ADD(2:0) = 3$ . Readback of internal registers and memories is indirect. The 16-bit indirect (internal) address of the desired read source is first written to direct (external) address 3,  $ADD(2:0) = 3$ , to select the data. The data can then be read at direct (external) addresses  $ADD(2:0) = 0$  and 1 (bits 15:0 at address 0 and 31:16 at address 1). The data types available via the indirect read are listed in the Tables of Indirect Read Address (IRA) Registers. (Note that the  $\mu PHold$  bit contained in the target register at Indirect Write Address (IWA) = \*00Ah must be set to suspend the filter compute engine before the coefficient RAM and instruction bit fields can be written to or read from.)

The ISL5216 output data from the four channels is available through the microprocessor interface as well as from the serial data outputs. A FIFO-like interface is used to read the output data through the microprocessor interface. When new output data is available, it is loaded into a FIFO in a user programmed order (for details on the programming order see Global Write Address (GWA) = F820h - F83Fh). It can then be read, 16 bits at a time, at direct address 2,  $ADD(2:0) = 2$ . At the end of each read, the FIFO counter is advanced to the

next location. This allows a DMA controller to read all of the data with successive reads to a single direct address. No writes or other interaction is required. The FIFO counter is reset and reloaded by each interrupt signal, see GWA F802h. New data in the FIFO is also indicated in the status register located at direct address  $ADD(2:0) = 3$  if a polled mode is preferred. The eight data types available, for each of the four channels, via this interface are:  $I(23:8)$ ,  $I(7:0)+8$  Zeroes,  $Q(23:8)$ ,  $Q(7:0)+8$  Zeroes,  $Mag(23:8)$ ,  $Mag(7:0)+8$  Zeroes, Phase (15:0), and AGC (15:0). The upper bits of  $I$ , i.e.,  $I(23:8)$ , and  $Q$ , i.e.,  $Q(23:8)$ , are not rounded to 16 bits. This interface can read the data from all the channels that are synchronized. However, because a common FIFO is used and the FIFO is reset and reloaded by each interrupt, it cannot be used for asynchronous channels.

The direct address map for the microprocessor interface is shown in the Table of Microprocessor Direct Read/Write Addresses and the procedures for reading and writing to this interface are provided below. The bit field details for each indirect read and write address is provided in the Table of Indirect Read Address (IRA) Registers, Tables of Indirect Write Address (IWA) Registers and Tables of Global Write Address (GWA) Registers in the following sections.

## **$\mu$ P Read/Write Procedures**

### **To Write to the Internal Registers:**

1. Load the indirect write holding registers at direct address ADD(2:0) = 0 and 1 with the data for the internal register (16 or 32 bits depending on the internal register being addressed).
2. Write the Indirect Write Address of the internal register being addressed to direct address ADD(2:0) = 2 (Note: A write strobe to transfer the contents of the Indirect Write Holding Register into the Target Register specified by the Indirect Address will be generated internally).
3. Wait four clock cycles before performing the next write to the indirect write holding registers.

### **To Write to the Internal Instruction/Coefficient RAMs:**

1. Put the filter compute engine of the desired channel into the hold mode by setting bit 31 of the Filter Compute Engine / Resampler Control register located at IWA = \*00AH (Note: The \* is equal to 0, 1, 2 or 3 depending on the channel being addressed). By setting bit 31 all FIR processing for the channel addressed will be stopped.
2. Load the indirect write holding registers at direct address ADD(2:0) = 0 and 1 with the data for the internal RAM location.
3. Write the Indirect Write Address of the internal RAM location being addressed to direct address ADD(2:0) = 2 (Note: A write strobe to transfer the contents of the Indirect Write Holding Register into the RAM location specified by the Indirect Address will be generated internally).
4. Wait four clock cycles before performing the next write to the indirect write holding registers.
5. After all data has been loaded, set the  $\mu$ PHold bit back low.

### **To Read Internal Registers:**

1. Write the Indirect Read Address of the internal register being addressed to direct address ADD(2:0) = 3.
2. Perform a read of the Indirect Read Holding Registers at direct address ADD(2:0) = 0 and 1.

### **To Read Data Outputs:**

1. Set up the  $\mu$ P FIFO Read Order Control Register (located at Global Write Address (GWA) = F820H - F83FH).
2. Wait for interrupt or check flag.
3. Data can then be read, 16 bits at a time, at direct address 2, ADD(2:0) = 2.
4. Repeat step 3 for desired number of words.
5. Go to step 2.

### **To Read Instruction/Coefficient Values:**

1. Put the filter compute engine of the desired channel into the hold mode by setting bit 31 of the Filter Compute Engine / Resampler Control register located at IWA = \*00AH (Note: The \* is equal to 0, 1, 2 or 3 depending on the channel being addressed).

2. Write the Indirect Read Address (IRA) of the internal RAM/ROM location being addressed to direct address ADD(2:0) = 3.
3. Wait four clock cycles.
4. Read the data at direct address ADD(2:0) = 0 and 1.
5. After all the data has been read, set the  $\mu$ PHold bit back low.

### **Recommended ISL5216 configuration procedure following a hardware reset (i.e. RESETb is pulsed low):**

1. Load Global Write Address registers GWA F800H - GWA F808H and GWA F820H - GWA F83FH.
2. For each signal processing channel (0-3):
  - a. Set  $\mu$ PHold bit located at Indirect Write Address register IWA \*00AH bit 31.
  - b. Load Filter Compute Engine Instruction RAMS.
  - c. Load Filter Compute Engine Coefficient RAMS.
  - d. Load IWA registers \*000H - \*019H and \*01CH. (Clear the  $\mu$ PHold bit in register IWA \*00AH bit 31).
  - e. Wait 32 clocks (CLK) for the reset to complete in the Filter Compute Engine.
3. Generate a SYNCI to enable the input data or to synchronize the processing to external events or generate a SYNCO and internal SYNCI by writing to GWA F80AH. A write to F809H will also work if the SYNCO pin is externally connected to the SYNCI pin.

### **Recommended ISL5216 Channel Reconfiguration Procedure:**

1. Disable the serial output for the desired channel in register GWA F801H - bits 3:0.
2. Disable the interrupts from the channel in register GWA F802H bits 31, 23, 15, and 7.
3. Set the  $\mu$ PHold bit in register IWA \*00AH bit 31 to give the processor access to the Filter Compute Engine Instruction RAMS and Coefficient RAMS.
4. Load the new filter configuration.
5. Load any other channel registers.
6. Clear the  $\mu$ PHold bit in register IWA \*00AH bit 31.
7. Do a software channel reset by writing to IWA \*019H.
8. Enable the serial outputs (GWA F801H) and interrupts (GWA F802H).
9. Generate a SYNCI to enable the input data or to synchronize the processing to external events or generate a SYNCO by writing to GWA F80AH or F809H (if SYNCO pin is tied to SYNCI pin).

## JTAG

JTAG: The IEEE1149.1 Joint Test Action Group boundary scan standard operational codes shown in Table 3 below are supported. A separate application note is available with implementation details.

**TABLE 3. JTAG OP CODES SUPPORTED**

INSTRUCTION	OP CODE
EXTEST	0000
IDCODE	0001
SAMPLE/PRELOAD	0010
INTEST	0011
BYPASS	1111

## Built in Self Test

Self-test is initiated by resetting the part and loading a given configuration register set and filter coefficient set. The self-test replaces the user programmed input with a PN sequence and calculates a 16 bit signature from the output data. This signature is compared to a user-provided signature and the result is provided as a bit in the status register. The BIST procedure is as follows:

1. Configure the part as described in "Recommended ISL5216 configuration procedure following a hardware reset" above.
2. (optional) Load the 16 bit comparison signature into GWA F80BH bits 15:0. This value will be compared to the device-calculated signature and reported in the status register. The device-calculated signature may also be read and the comparison performed in the user's microcontroller.
3. Write 00000000H to F019H to perform a software reset of all channels.
4. Write 00000001H to GWA F800H to start the first phase of the self test.
5. Wait until bit 0 of F800H is cleared indicating the first phase of self test has completed.
6. Write 00000000H to F019H to reset all channels again.
7. Write 00000001H to GWA F800H to start the second phase of the self test.
8. Wait until bit 0 of F800H is cleared indicating the second phase of self test has completed.
9. If a comparison signature has been supplied (step 2), bit 12 of the status register (direct read address register 3) is set to 1 if the signature matches the ISL5216-generated signature.
10. The ISL5216-generated signature may be read from GWA F80BH bits 31:16. The user-supplied signature (step 2) may be also be read back from bits 15:0.

## Filter Compute Engine Data RAM Test

The ISL5216 provides read / write access to the data RAM used by a channel's filter compute engine. To access the data RAM for testing, set bit 15 of GWA F800H. Data must be written to the RAM in Q / I pairs - 24 bit Q first, then 24 bit I. Q and I samples are written to the RAM using the indirect addresses shown in the table below (see *To Write to the Internal Registers* above for the indirect write procedure). Reading of the registers may occur in any order. The table below provides the valid address range in data RAM test mode. Note that addresses \*000H - \*6FFH are valid with the exception of \*300H - \*3FFH. \* = 0, 1, 2, or 3 for channels 0 through 3, respectively. F800H bit 15 must be cleared after data RAM testing to return to normal operation.

**DATA RAM ADDRESS MAP**

INDIRECT ADDRESS (Note 18)	DATA
*000H	Q sample 0
*001H	I sample 0
*002H	Q sample 1
*003H	I sample 1
:	:
*2FEH	Q sample 767
*2FFH	I sample 767

## Tables of Indirect Write Address (IWA) Registers

NOTE: These Indirect Write Addresses are repeated for each channel. In the addresses below, the \* field is the channel select nibble. These bits of the Indirect Address select the target channel

register for the data. Values of 0 through 3 and F are valid. A channel select nibble value of F is a special case which writes the data to the same location in each of the four channels simultaneously.

**TABLE 4. CHANNEL INPUT SELECT/FORMAT REGISTER (IWA = \*000h)**

P(31:0)	FUNCTION												
24	Upper Side Band/Lower Side Band select for use in complex input mode.												
23	For complex input mode: when set to 1, the I sample is taken when $\overline{\text{ENIX}}$ is active and the Q sample is taken on the next clock. When set to 0, Q sample is taken two clocks after $\overline{\text{ENIX}}$ is active.												
22	Complex input enable. Set to 1 for complex input mode, 0 for real input mode.												
21	If set, adjusts the alignment between input data enables and NCO enables to allow unevenly spaced input samples in the gated input mode. This may be set to 0 to align processing delays with the HSP50216 if necessary.												
20:18	Floating point exponent saturation level. Used with floating point modes to set the maximum exponent code level 000 to 111. These bits are protection against overflow due to an invalid exponent for the programmed CIC shift code. Set to 111 to disable.												
17	Enables the new (ISL5216) floating point modes -- the 11, 12, 13 and 14-bit modes with 42 dB of gain, and 15 and 16-bit modes with 18 dB and 6 dB ranges, respectively. The X-1 input must be used for 14, 15 and 16-bit modes. See Floating Point Input Mode Bit Mapping Tables for details.												
16	Floating point mode select bit 2. Used with IWA *000, bits 8:7 to select the floating point mode/format. See Floating Point Input Mode Bit Mapping Tables for details.												
15:13	Channel Input Source Selection - Selects as the data input for the channel specified in the Indirect Address either A(15:0), B(15:0), C(15:0), D(15:0) or the $\mu\text{P}$ Test Input register as shown below: <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>15:13</th> <th>SOURCE SELECTED</th> </tr> </thead> <tbody> <tr> <td>000</td> <td>A(15:0)</td> </tr> <tr> <td>001</td> <td>B(15:0)</td> </tr> <tr> <td>010</td> <td>C(15:0)</td> </tr> <tr> <td>011</td> <td>D(15:0)</td> </tr> <tr> <td>100</td> <td><math>\mu\text{P}</math> Test input register. This is provided for testing and to zero the input data bus when a channel is not in use. The Global Write Address register for the <math>\mu\text{P}</math> Test input register is F807h.</td> </tr> </tbody> </table>	15:13	SOURCE SELECTED	000	A(15:0)	001	B(15:0)	010	C(15:0)	011	D(15:0)	100	$\mu\text{P}$ Test input register. This is provided for testing and to zero the input data bus when a channel is not in use. The Global Write Address register for the $\mu\text{P}$ Test input register is F807h.
15:13	SOURCE SELECTED												
000	A(15:0)												
001	B(15:0)												
010	C(15:0)												
011	D(15:0)												
100	$\mu\text{P}$ Test input register. This is provided for testing and to zero the input data bus when a channel is not in use. The Global Write Address register for the $\mu\text{P}$ Test input register is F807h.												
12	$\mu\text{P}$ Test Register input enable selection: 1 Bit 11 of this register is used as the input enable. 0 A one clock wide pulse generated on each write to IGWA F808h is used as the input enable. Select 0 to write test data into the part. Select 1 to input a constant or to disable the input for minimum power dissipation when an NCO/mixer/CIC section is unused.												
11	$\mu\text{P}$ input enable. When bit 12 is set, this bit is the input enable for the $\mu\text{P}$ Test Register input. Active low: 0 Enabled 1 Disabled.												
10	Parallel Data Input Format: 0 Two's complement (-full scale = 1000...0000, zero = 0000...0000, +full scale = 0111...1111). 1 Offset binary (-full scale = 0000...0000, zero = 1000...0000, +full scale = 1111...1111).												
9	Fixed/Floating point: 0 Fixed point. 1 Floating point. The 17-bit input bus is divided into 11 to 16 mantissa bits and 1 to 3 exponent bits depending on bits 17, 16, 8 and 7. See Floating Point Input Mode Bit Mapping Tables for details.												
8:7	Floating point mantissa size select bits 0 and 1. See Floating Point Input Mode Bit Mapping Tables for details.												

TABLE 4. CHANNEL INPUT SELECT/FORMAT REGISTER (IWA = \*000h) (Continued)

P(31:0)	FUNCTION
6:4	<p>De-multiplex control. These control bits are provided to select a channel from a group of multiplexed channels. Up to eight multiplexed data streams can be demultiplexed. These control bits select how many clocks after the <math>\overline{\text{ENix}}</math> signal to wait before taking the input sample. <math>\overline{\text{ENix}}</math> should be asserted for one clock period and aligned with the first channel of the multiplexed data set. For example, if four streams are multiplexed at half the clock rate, <math>\overline{\text{ENix}}</math> would align with the first clock period of the first stream, the second would start two clocks later, the next four clocks after <math>\overline{\text{ENix}}</math>, etc. The samples are aligned with <math>\overline{\text{ENix}}</math> (zero delay) at the input of the NCO/Mixer/CIC stage at the next <math>\overline{\text{ENix}}</math>.</p> <p>000 Zero delay 111 Seven clock periods of delay. All values from 0 through 7 are valid.</p>
3	<p>Interpolated/Gated Mode Select:</p> <p>0 Gated. The carrier NCO and CIC are updated once per clock when <math>\overline{\text{ENix}}</math> is asserted. 1 Interpolated. The CIC is updated every clock. The carrier NCO is updated once per clock when <math>\overline{\text{ENix}}</math> is asserted. The input is zeroed when <math>\overline{\text{ENix}}</math> is high.</p>
2	Enable COF/COFSYNC inputs. When set, this bit enables two bits from the D(15:0) input data bus to be used as a carrier offset frequency input.
1	Enable SOF/SOFSYNC inputs. When set, this bit enables two bits from the D(15:0) input data bus to be used as a resampler offset frequency input.
0	Enable PN. When set, A PN code, weighted by the gain in location *001, is added to the input samples at the output of the mixer.

TABLE 5. FLOATING POINT MODE DETAILS (IWA = \*000h, BITS 17, 16, 8 and 7)

BIT 17	BIT 16	BIT 8	BIT 7	MANTISSA / EXP	EXPONENT RANGE (dB)	PIN ASSIGNMENTS: MANTISSA BITS / EXPONENT BITS
0	X	0	0	11 to 13 / 3	30	15:5 (4 or 3) (Note 19) / 2:0
0	X	0	1	12 to 13 / 3	24	15:4 (3) / 2:0
0	X	1	0	13 / 3	18	15:3 / 2:0
0	X	1	1	14 / 2	18 maximum (Note 20)	15:2 / 1:0
1	0	0	0	11 / 3	42 maximum	15:5 / (2 logical-OR m1), 1, 0
1	0	0	1	12 / 3	42 maximum	15:4 / (2 logical-OR m1), 1, 0
1	0	1	0	13 / 3	42 maximum	15:3 / (2 logical-OR m1), 1, 0
1	0	1	1	14 / 3	42 maximum	15:2 / m1, 1, 0
1	1	0	0	15 / 2	18 maximum	15:1 / m1, 0
1	1	0	1	16 / 1	6 maximum	15:0 / m1
1	1	1	X	INVALID	INVALID	INVALID

NOTES:

19. Bits in parentheses are used as the shift gain allows.

20. Modes with "maximum" listed in exponent range use the CIC's barrel shifter for gain, decreasing allowable CIC decimation. Maximum exponent range may be limited, if desired, to allow for larger CIC decimation.

TABLE 6. PN GAIN REGISTER (IWA = \*001h)

P(31:0)	FUNCTION
31:16	Reserved, set to all 0's.
15:0	PN generator gain register. This input is provided to reduce the sensitivity of the receiver. A PN code, weighted by the value in this location, is added to the data at the output of the mixer. Adding noise has the effect of increasing the receiver noise figure. One reason to do this would be to decrease the basestation cell size in small steps. This method is very accurate and repeatable and can be done on a FDM channel by channel basis. It does, however, reduce the overall dynamic range. An alternate way is to add attenuation at the RF and adjust the whole range upward. This does not reduce the overall range but only shift it, with the shift being done on all channels simultaneously.

TABLE 7. CIC DECIMATION FACTOR REGISTER (IWA = \*002h)

P(15:0)	FUNCTION
15:0	Load with the desired CIC decimation factor minus 1.

TABLE 8. CIC DESTINATION FIR AND OUTPUT ENABLE/DISABLE REGISTER (IWA = \*003h)

P(15:0)	FUNCTION
15:6	Set to zero.
5:1	CIC output destination (FIR # in FIR processor). Usually set to 00001.
0	CIC output enable. Active high. When low, the data writes from the CIC to the filter compute engine are inhibited.

TABLE 9. CARRIER NCO/CIC CONTROL REGISTER (IWA = \*004h)

P(31:0)	FUNCTION									
31:20	Reserved, set to zero.									
19:14	CIC barrel shift control.  000000 is the minimum shift factor and 101111 (47 decimal) is maximum shift factor. 000000 = Shift Factor of 0; 011111 = Shift Factor of 31; 100000 = Shift Factor of 32; 101111 = Shift Factor of 47. This compensates for the CIC filter gain of $R^N$ , where N is the number of enabled CIC stages and R is the CIC decimation factor. The equation used to compute the shift factor is: Shift Factor = 45 - Ceiling( $\log_2(R^N)$ ). Use a shift of 45 decimal when bypassing the CIC. Note that shifts of 46 and 47 may cause loss of MSBs.  Examples: <table border="0"> <tr> <td>N</td> <td>R</td> <td>Shift Factor</td> </tr> <tr> <td>5</td> <td>512</td> <td>0</td> </tr> <tr> <td>5</td> <td>8</td> <td>30</td> </tr> </table>	N	R	Shift Factor	5	512	0	5	8	30
N	R	Shift Factor								
5	512	0								
5	8	30								
13:9	CIC stage bypasses. The integrator/comb pairs are numbered 1 thru 5, with 1 being the first integrator and first comb. Bit 13 bypasses the first integrator/comb pair, bit 12 bypasses the second, etc. The first integrator is the largest. Typically, the stages are enabled starting with stage 1 for maximum decimation range.									
8:6	Carrier phase shift. Phase shifts of $N*(\pi/4)$ , N = 0 to 7. These bits remain for backward compatibility with the HSP50216. For new designs, these bits should be set to 0 and the phase offset programmed into IWA *01CH.									
5	Clear feedback (test signal or for mixer bypass).									
4	NCO clear feedback on load.									
3	Update frequency on SYNCI. Redundant. Set to 1. See GWA register F802h.									
2:1	Number of Carrier Offset Frequency (COF) serial input bits. The format is 2's complement, early SYNC, MSB first:  <table border="0"> <tr> <td>00</td> <td>8</td> </tr> <tr> <td>01</td> <td>16</td> </tr> <tr> <td>10</td> <td>24</td> </tr> <tr> <td>11</td> <td>32</td> </tr> </table>	00	8	01	16	10	24	11	32	
00	8									
01	16									
10	24									
11	32									
0	Enable serial carrier offset frequency (zeros the data already loaded via the COF/COFSYNC pins). To disable the COF shifting see IWA register *000h.									

TABLE 10. CARRIER NCO CENTER FREQUENCY REGISTER (IWA = \*005h)

P(31:0)	FUNCTION
31:0	Carrier Center Frequency (CCF):  This is the frequency control for the carrier NCO. The center frequency control is double buffered. The contents of this register are transferred to the active register on a write to the CCF Strobe location or on a SYNCI (if load on SYNCI is enabled). The carrier center frequency is: $CCF * f_{CLK} / (2^{32})$ . CCF is a twos complement number and has a range of $-2^{31}$ to $(2^{31}-1)$ . $f_{CLK}$ is the input sample rate ( $\overline{ENix}$ assertion rate) for gated mode and the clock rate for interpolated mode. The value in the active register can be read at this address (the center frequency control before the serially loaded offset value is added). To read the value, either write this address to A(1:0) = 11 and then read at A(1:0) = 00 and 01, or read the value at A(1:0) = 00 and 01 after writing to this address and before writing a new address to either A(1:0) = 10 or 11.

TABLE 11. CARRIER NCO CENTER FREQUENCY UPDATE STROBE REGISTER (IWA = \*006h)

P(15:0)	FUNCTION
N/A	Writing to this address generates a strobe that transfers the CCF value to the active frequency register. The transfer to the active register can also be done using the SYNCl pin to synchronize the transfer in multiple parts or to synchronize to an external event.

TABLE 12. TIMING NCO FREQUENCY CONTROL REGISTER, MSW (IWA = \*007h)

P(31:0)	FUNCTION
31:0	These are the upper 32 bits of the 56-bit timing (resampler) NCO center frequency control.

TABLE 13. TIMING NCO FREQUENCY CONTROL REGISTER, LSW (IWA = \*008h)

P(31:0)	FUNCTION
31:8	These are the lower 24 bits of the 56-bit timing (resampler) NCO center frequency control.
7:0	Unused, set to zero.

TABLE 14. TIMING NCO CENTER FREQUENCY LOAD STROBE REGISTER (IWA = \*009h)

P(31:0)	FUNCTION
N/A	A write to this location will update the resampler NCO center frequency.

TABLE 15. FILTER COMPUTE ENGINE/RESAMPLER CONTROL REGISTER (IWA = \*00Ah)

P(31:0)	FUNCTION
31	$\mu$ PHold. When set, this bit stops the filter compute engine and allows the $\mu$ P access to the instruction and coefficient RAMs for reading and writing. On the high to low transition, the filter compute engine is reset (the read and write pointers are reset and the instruction at location 31 is fetched).
30	$\mu$ PShiftZeroB. This bit, when set to zero, disables the coefficient shift bits (bits 9:8 of the master register when coefficient loading).
29	$\mu$ PEN Limit. This bit disables the data path saturation logic. Provided for test. Active high. Set to 0 to disable the normal ROM controlled limiting (ANDed with normal signal).
28:24	$\mu$ PZ(4:0). These bits, when set to 0, zero the corresponding read pointer address bits. This allows the pointers to be aliased, i.e., multiple filters can access and/or modify the same pointer. They are provided to change filters, coefficients or decimation over a sequence.
23	Unused, set to 0.
22	Timing (resampler) NCO ENSync. If this bit is set, the center frequency is updated on a SYNCl. Set to 1.
21:20	RSRVRS(1:0). Set to 01.
19	Beginning/ $\overline{\text{End}}$ . This bit selects whether the resampler NCO is updated at the beginning of a FIR computation or at the end of each FIR output computation. Usually, the resampler will be updated once at the beginning of each resampler computation and this will be bit set to 1. 1 Once at the beginning of the FIR instruction. 0 At the last tap of each of the instruction's FIR computations (once per output).
18	RSMoDeSelect. This bit selects whether the resampler is a phase shifter or a frequency shifter. 0 Phase shift. It uses the top five bits of the timing NCO frequency to determine a phase shift and disables feedback in the timing NCO phase accumulator—effect of the resampler is a constant phase shift. 1 Frequency shift. Effect of the resampler is a change in the sample rate.
17	RSCO. This bit is provided to force the resampler NCO carry when using the resampler as a phase shifter rather than for a frequency shift. This bit must be set for phase shifting and cleared for frequency shifting. (The bit is Or-ed with the normal carry.)
16	RS NCO clear phase accumulator feedback on load. When this bit is set, the feedback in the resampler NCO phase accumulator is zeroed whenever the center frequency word is updated. This forces the NCO to a known phase so the phase of multiple channels can be aligned.
15	Force NCO load. This bit, when set, zeroes the feedback in the resampler NCO phase accumulator. This is provided for test or to use the resampler for phase instead of frequency shifting.

**TABLE 15. FILTER COMPUTE ENGINE/RESAMPLER CONTROL REGISTER (IWA = \*00Ah) (Continued)**

P(31:0)	FUNCTION
14	Enable RS freq offset. This bit, when set, enables the serially loaded resampler offset frequency word. When zero, the offset is zeroed. To disable the shifting, see IWA register *000h.
13:12	Serial input word size. These bits select the number of bits in the resampler offset frequency word (loaded serially via SOF/SOFSYNC). 00 8 bits 01 16 bits 10 24 bits 11 32 bits
11:0	FIFODelay. A FIFO is provided at the output of the filter compute engine to smooth the sample spacing when using the resampler or interpolation FIRs. In these filters, the outputs can be produced in bursts or with gaps. The FIFO takes the samples in and outputs them based on a counter timeout. If the FIFO is empty and the counter is at its terminal count (hold state), the data is passed through and the counter is reloaded. If the counter is not at terminal count, the data is held in the FIFO until the counter times out. The FIFO can hold up to 4 samples. The delay is programmed in clock periods. The value programmed is one less than the number of clocks of delay. Set to 0 for a delay of one (fall through). The delay should be programmed to slightly less than the desired spacing to prevent overflow.

**TABLE 16. FILTER START OFFSET REGISTER (IWA = \*00Bh)**

P(15:0)	FUNCTION
13:9	RAM Instruction number to which the offset is applied. 0–31. Aliasing applies. Used for polyphase filters.
8:0	Amount of offset. Offsets the data RAM address for filter #n. This is used to offset the channels from each other when breaking the processing up among multiple channels for polyphase filters. For example, four channels can receive the same data at 8MSPS, filter and decimate by 8 to output at 1MHz. If the computations are offset by two samples each, then the outputs of the four channels can be multiplexed together to get an output sample rate of 4MSPS. With a 64MSPS clock, the composite filter could have more than 100 taps where a single channel would only be capable of around 24 taps at a 4MHz output. EXCEPT IN VERY RARE CIRCUMSTANCES, THIS VALUE SHOULD BE A NEGATIVE NUMBER.

**TABLE 17. WAIT THRESHOLD/DECREMENT VALUE REGISTER (IWA = \*00Ch)**

P(31:0)	FUNCTION
31	μPTestBit. This bit is provided as a microprocessor controlled condition code for the filter compute engine for conditional execution or synchronous startup. Active high.
30	Set to 0.
29:20	Decrement value 1. Positive number.
19:10	Decrement value 0. Positive number. Usually set equal to the Threshold (bits 9:0).
9:0	Threshold. Number of samples needed to run a filter set and produce an output.

**TABLE 18. RESET WRITE POINTER OFFSET REGISTER (IWA = \*00Dh)**

P(15:0)	FUNCTION
15:9	Set to zero.
8:0	This parameter is the offset between filter compute engine read and write pointers on filter compute engine reset. On reset, the read and write pointers for all the filters are loaded, the read pointer with zero and the write pointer with this value. Set to 0 for a single filter and 2 for a multi-filter chain.

**TABLE 19. AGC GAIN LOAD REGISTER (IWA = \*00Eh)**

P(15:0)	FUNCTION
15:0	This location loads the AGC accumulator. If the loop attack/decay gain is set to zero and this value is within the AGC gain limits, the AGC will hold this value. If not, the AGC will be set to this gain (or to a limit) and then start to settle. format is four exponent bits (15:12), and 12 mantissa bits, (11:0).

TABLE 20. AGC GAIN READ STROBE REGISTER (IWA = \*00Fh)

P(15:0)	FUNCTION
15:0 for $\overline{RD}$ ; N/A for $\overline{WR}$	Writing to this location will sample the AGC loop filter output (forward gain value) to stabilize it for reading. The value is read from this location after waiting the four clocks required for synchronization.

TABLE 21. AGC LOOP ATTACK/DECAY GAIN VALUES REGISTER (IWA = \*010h)

P(31:0)	FUNCTION
31:24	Loop gain 0, decay gain value (signal decay, increase gain) 31:28 = EEEE (exponent), 27:24 = MMMM (mantissa).
23:16	Loop gain 1, decay gain value 23:20 = EEEE (exponent), 19:16 = MMMM (mantissa).
15:8	Loop gain 0, attack gain value (signal arrival, decrease gain) 15:12 = EEEE (exponent), 11:8 = MMMM (mantissa).
7:0	Loop gain 1, attack gain value 7:4 = EEEE (exponent), 3:0 = MMMM (mantissa).

TABLE 22. AGC GAIN LIMITS REGISTER (IWA = \*011h)

P(31:0)	FUNCTION
31:16	Upper gain limit. See AGC section.
15:0	Lower gain limit. See AGC section.

TABLE 23. AGC THRESHOLD REGISTER (IWA = \*012h)

P(31:0)	FUNCTION
15:0	AGC threshold. Equals 1.64676 times the desired magnitude of the I1/Q1 output.

TABLE 24. AGC/DISCRIMINATOR CONTROL REGISTER (IWA = \*013h)

P(15:0)	FUNCTION
15:11	Set to zero.
10	$\mu$ P AGC loop gain select.
9	Enable filter compute engine control of AGC loop gain. When this bit is set, bit 28 in the filter compute engine destination field selects which loop gain to use with that filter output's gain error. Setting bit 10 overrides this bit and forces a loop gain 1.  10:9   FUNCTION 00    Loop Gain 1 ( $\mu$ P controlled) 10    Loop gain 0 ( $\mu$ P controlled) 01    Loop Gain controlled by filter compute engine 11    Loop 1 ( $\mu$ P override of filter compute engine)
8	Mean/Median. This bit controls the settling mode of the AGC. Mean mode settles to the mean of the signal and settles asymptotically to the final value. Median mode settles to the median and settles with a fixed step size. This mode settles faster and more predictably, but will have more AM after settling.  1    Mean mode 0    Median mode
7	dphi / dt strobe enable. Set this bit to 1 to get a dphi/dt output without having to feed back through the filter compute engine.
6	Unused. Set to zero.
5	PhaseOutputSel  1    d $\phi$ /dt 0    Phase
4:3	DiscShift(1:0). Shifts the phase up 0-, 1-, 2-, or 3-bit positions, discarding the bits shifted off the top. This makes the phase modulo 360, 180, 90, or 45 degrees to remove PSK modulation. The resulting phase is 18 bits.
2:0	DiscDelay(2:0). Sets the delay, in sample times, for the d $\phi$ /dt calculation.  000   1 111   8

TABLE 25. SERIAL DATA OUTPUT CONTROL REGISTER (IWA = \*014h)

P(31:0)	FUNCTION
31:29	Set to zero.
28	Sync polarity 1 Active low (low for one serial clock per word with a sync). 0 Active high.
27:26	Reserved, set to zero.
25:24	Sync position. This applies to all time slots in the serial output. The Sync programming is associated with the SD1x serial output data stream (x = A, B, C, or D).  00 Sync is asserted during the serial clock period prior to the first data bit of the serial word (early sync). 01 Sync is asserted during the clock period following the last data bit of the word (late sync). 1X Sync is asserted during the serial clock period of the first data bit of the serial word (coincident sync).
23:22	Reserved, set to zero.
21:20	Magnitude output scale factor. The magnitude output of the cartesian to polar coordinate conversion has bits weighted as: $2^{(2 \ 1 \ 0 \ -1 \ -2 \ -3 \ -4 \ \dots)}$ The gain in the conversion is 0.82338. When using 16 bits, the range is such that the LSB has a weight of 0.00007 and the maximum output is 2.32, both after the conversion gain. This corresponds to an I/Q vector length of -83dBFS to +3dBFS. These control bits add gain (with saturation) for more resolution at the bottom of the scale. A code of 00 passes the magnitude unchanged, 01 shifts the magnitude up one bit position' 10 shifts by two positions and 11 shifts up three positions. The resulting bit weights and range (after conversion gain) for the unsigned numbers are:  Code Bit Weights dBFS 00 2 1 0 -1 -2 . . . -11 -12 -13 +3 to -83 01 1 0 -1 -2 -3 . . . -12 -13 -14 +3 to -89 10 0 -1 -2 -3 -4 . . . -13 -14 -15 +1.7 to -95 11 -1 -2 -3 -4 -5 . . . -14 -15 -16 -4.3 to -101 The upper limits on codes 00 and 01 are the same, but 01 has no leading zero.
19:16	Serial data output SD1 routing mask. 0 disables. 1 enables.  Bit Enabled Output 16 Enables the serial output for this channel to pin SD1A. 17 Enables the serial output for this channel to pin SD1B. 18 Enables the serial output for this channel to pin SD1C. 19 Enables the serial output for this channel to pin SD1D.
15:12	Serial data output SD2 routing mask. 0 disables. 1 enables.  Bit Enabled Output. 12 Enables the serial output for this channel to pin SD2A. 13 Enables the serial output for this channel to pin SD2B. 14 Enables the serial output for this channel to pin SD2C. 15 Enables the serial output for this channel to pin SD2D.
11:0	Output hold-off delay. This parameter adds additional delay from the output of the filter compute engine to start of the serial output stream for multiplexing channels. Load with the desired delay (0 = zero, 1 = one, 2 = two, etc.).

TABLE 26. SERIAL DATA OUTPUT 1 CONTENT/FORMAT REGISTER 1 (IWA = \*015h)

P(15:0)	FUNCTION
N/A	<p>Writing to this location resets the following activities of the functional block indicated.</p> <p>Input Format/Select, NCO, Mixer and CIC.</p> <p>Clears any pending enable in each channel's input demultiplexer function, loads the CIC decimation counter (the load value is indeterminate if the decimation counter preload register has not been loaded), clears all processing enables (stops all processing in the data path, but does not clear the data path registers).</p> <p>Filter Compute Engine:</p> <p>Resets the Read/Write pointers, fetch instruction 31 and start the filter program execution.</p> <p>AGC:</p> <p>Resets the compute blocks in both the forward and loop filter blocks (any calculations in progress are lost).</p> <p>Cartesian-to-Polar Coordinate Converter:</p> <p>Resets the compute blocks (any calculations in progress are lost).</p> <p>FIFO:</p> <p>Resets counter (clears the FIFO, all data is lost).</p> <p>Resampler Timing NCO:</p> <p>Clears the slave (active) frequency registers and clears the phase accumulator.</p> <p>Output Section:</p> <p>Resets the serial output section (clears all registers, counters, and flags but does not clear the configuration registers).</p> <p>Self Test Control:</p> <p>Resets the self test control logic of the front end (Input Format/Select, NCO, Mixer, and CIC) and the back end (Filter Compute Engine, AGC, and Cartesian-to-Polar Coordinate Converter).</p>

**TABLE 31. CHANNEL TIMING ADVANCE STROBE REGISTER (IWA = \*01Ah)**

P(15:0)	FUNCTION
N/A	Writing to this location inserts one extra data sample in the CIC to FIR path by repeating a sample. Used for shifting the FIR filter compute engine timing.

**TABLE 32. CHANNEL TIMING RETARD STROBE Register (IWA = \*01Bh)**

P(15:0)	FUNCTION
N/A	Writing to this location deletes one data sample in the CIC to FIR path. Used for shifting the FIR filter compute engine timing.

**TABLE 33. CARRIER PHASE OFFSET (IWA = \*01Ch)**

P(15:0)	FUNCTION
15:0	Carrier phase offset. Values of 0000H - FFFFH in this register represent phase shifts of 0 to 65535 / 65536 * 360 degrees (this value may also be interpreted as a signed integer, in which case the range 8000H - 7FFFH corresponds to phase shifts of -180 to 32767 / 32768 * 180 degrees). For the HSP50216 backward compatibility, the original 3-bit phase offset (IWA *004 bits 8:6) is added to the new 16-bit phase offset register. HSP50216 configurations use IWA *004. New configurations should set *004 bits 8:6 to zero and use this register. This register is set to 0 by the reset pin.

TABLE 34. FILTER COMPUTE ENGINE INSTRUCTION RAMS (IWA = \*100h THRU \*17Fh)

P(31:0)	FUNCTION
31:0	These locations in RAM are used to store the Filter Compute Engine instruction words. There are 128 bits per instruction word with each word consisting of condition code selects, FIR parameters and data routing controls. The filter compute engine is controlled by a simple sequencer supporting up to 32 steps where each step is defined by a 128-bit instruction word. This instruction word is assigned to RAM memory in four 32-bit data writes through the Microprocessor Interface starting with the low 32 bits. Hence, 128 32-bit memory locations are required per channel to support the 32 steps of the Filter Sequencer. See the <i>Filter Compute Engine</i> and <i>Filter Sequencer</i> sections of the data sheet for more details.

TABLE 35. FILTER COMPUTE ENGINE INSTRUCTION POINTER RAMS (IWA = \*180h THRU \*1FCh)

P(15:0)	FUNCTION
	(no programming required)

TABLE 36. FILTER COMPUTE ENGINE COEFFICIENT RAM (IWA = \*440h THRU \*4FFh)

P(31:0)	FUNCTION
31:8	These locations in RAM are used to store the 22-bit filter coefficients used by the Filter Compute Engine of each channel in implementing a FIR filter. The 22-bit FIR filter coefficients are loaded in the upper 22 bits of each 32-bit RAM location. The two LSBs of the second byte (bits 9:8 of the total 32 bits, 31:0) are the shift bits. These are set to zero if not used. The least significant byte (bits 7:0 of the total 32 bits, 31:0) are ignored. The coefficient RAM address space allows for storage of 192 filter coefficients storage locations. See the <i>Filter Compute Engine</i> and <i>Filter Sequencer</i> sections of the data sheet for more details.

## Tables of Global Write Address (GWA) Registers

NOTE: These Global Write Addresses control global functions on the ISL5216, so they are not repeated for each channel. The top five address bits select this set of registers (F8XXh).

TABLE 37. TEST CONTROL REGISTER (GWA = F800h)

P(31:0)	FUNCTION
31:21	These bits can be routed to the output pins by setting bit 16 below. The bit to pin mapping is: 31 = Intrpt      30 = SYNCO      29 = SERCLK (unless x1 CLK is selected) 28 = SYNCA      27 = SYNCB      26 = SYNCC      25 = SYNCD 24 = SD1A      23 = SD1B      22 = SD1C      21 = SD1D This is provided for testing board level interconnects. To control the SERCLK output, a divided down clock must be selected in the serial clock control register (GWA = F803h).
20:17	Unused - set to zero.
16	This bit, when high, routes bits 31:17 to the output pins in place of the normal outputs.
15	Data RAM test access enable: set to 1 to access data RAM for testing, set to 0 for normal operation
14:10	Unused - set to zero.
9	Set to 0.
8	Set to 0.
7:4	These bits, when set, route the MSB of the SIN output of the channel's carrier NCO to the number two serial output pin in place of the normal output. 7=CH0 6=CH1 5=CH2 4=CH3.
3	Offset I PN by XORing bit 10 of the PN generator with the output PN.
2	Enable ( $2^{23} - 1$ ) PN generator. The PN signal that can be added to the mixer output of each channel is produced from a ( $2^{23} - 1$ ) sequence, a ( $2^{15} - 1$ ) sequence or both. Two separate generators are provided. The outputs of both are XORed together to extend the repeat period. Either or both generators can be disabled. The XORed output can further be XORed with a delayed version of the ( $2^{23} - 1$ ) sequence on the I channel to decorrelate it from the Q channel. Otherwise, the same sequence will be used on both I and Q.
1	Enable ( $2^{15} - 1$ ) PN generator.
0	Test mode. When asserted, this bit puts the chip into internal (self) test mode. Set to 1 to enter a Self Test Mode.

TABLE 38. BUS ROUTING CONTROL REGISTER (GWA = F801h)

P(31:0)	FUNCTION
31:24	Unused - set to zero.
23:20	Interrupt pulse width. The width of the interrupt pulse at the pin can be programmed to be from 1 to 15 clocks wide. Program with the desired number of clocks. (NOTE: The pulse counter is only reset with the RESET pin. If a channel is reset by software or a SYNCI, any interrupt pulse in process will finish).
19:17	Set to 0.
16	CH1 or CH3 AGC to CH0 ext AGC. This bit selects whether the AGC loop filter output from CH1 or CH3 is routed to the external AGC gain input of CH0. 0=CH3, 1=CH1.
15:14	CH3 ext source mux sel. These bits select whether the CH2 source mux, CIC2, or FIR2out is routed to the external input of FIR3. 0=CH2srcmux, 1=FIR2, 2=CIC2.
13	CH2 ext source mux sel. This bit selects whether the CH1 external source mux or FIR1out is routed to the external input of FIR2. 0=CH1srcmux, 1=FIR1out.
12	CH1 ext source mux sel. This bit selects whether the CIC0 output or FIR0out is routed to the external input of FIR1. 0=CIC0, 1=FIR0out.
11	Set to 0.
10	CH1 backend input sel 0=CIC1, 1=CH1 ext src mux.
9	CH2 backend input sel 0=CIC2, 1=CH2 ext src mux.
8	CH3 backend input sel 0=CIC3, 1=CH3 ext source mux.
7	CH0 Ext AGC input enable. 0=CH0 loop filt, 1=external input.
6	CH1 Ext AGC input enable 0=CH1 loop filt, 1=external input.
5	CH2 Ext AGC input enable 0=CH2 loop filt, 1=external input.
4	CH3 Ext AGC input enable Set to 0.
3	CH0 enable serial output 1=FIR0 out enabled to serial outputs.
2	CH1 enable serial output 1=FIR1 out enabled to serial outputs.
1	CH2 enable serial output 1=FIR2 out enabled to serial outputs.
0	CH3 enable serial output 1=FIR3 out enabled to serial outputs.

TABLE 39. RESET/SYNC/INTERRUPT SOURCE SELECTION REGISTER (GWA = F802h)

P(31:0)	FUNCTION
31	When set, an interrupt will be generated on each data output of channel 0 to the output block. Typically, this bit will only be set for one channel.
30	When set, the data input to the part will be disabled (the input enable will be zeroed and held at zero) on a $\mu$ P reset (this is always true for the reset pin, whether this bit is set or not, and additionally, the reset pin sets the input mode to gated). The input enable will be released for the input sample that aligns with the SYNCI signal. This is a method for starting up the processing synchronous with a particular data sample.
29	When this bit is set, the carrier center frequency will be updated from the holding register (IWA = *005h) to the active register on the SYNCI signal. If the bit is set in register IWA = *004h to clear the phase accumulator feedback on loading, this function will synchronize the phase of multiple channels. After initial synchronization, the bit in IWA = *004h can be cleared and updates will be synchronous and phase continuous across channels.
28	When this bit is set, the FIR filter compute engine is reset on SYNCI. Resetting the FIR filter compute engine requires 32 clock (CLK) cycles to initialize the read and write pointers.
27	When this bit is set, the AGC is reset on SYNCI.
26	This bit has the same function as bit 29, but for the timing (resampler) NCO. The bit to zero the phase accumulator feedback is in register IWA = *00Ah.
25	When this bit is set, the CIC decimation counter is reset on SYNCI.
24	When this bit is set, the serial output block is reset on SYNCI. If bit 4 in location GWA F803h is set, the serial clock divider is also reset.
23:16	Same functions as 31:24 for channel 1.
15:8	Same functions as 31:24 for channel 2.
7:0	Same functions as 31:24 for channel 3.

TABLE 40. SERIAL CLOCK CONTROL REGISTER (GWA = F803h)

P(15:0)	FUNCTION
5	When set to 1, this bit will keep the serial clock disabled after a hardware reset until receipt of the first SYNCI signal.
4	Enables resetting serial clock divider on SYNCI. When enabled, a SYNCI enabled for any of the four serial data outputs in the Reset/Sync register (GWA = F802h, bits 24, 16, 8 or 0) will reset the serial clock divider.
3	SCLK polarity. 1 Clock low to high transition occurs at the center of the data bit. 0 Clock high to low transition at the center of the data bit.
2:0	SCLK rate. 000 Serial clock disabled. 001 Serial clock rate is Input CLK Rate. 010 Serial clock rate is Input CLK Rate/2. 011 Serial clock rate is Input CLK Rate/4. 100 Serial clock rate is Input CLK Rate/8. 101 Serial clock rate is Input CLK Rate/16. Other codes are undefined.

TABLE 41. INPUT LEVEL DETECTOR SOURCE SELECT/FORMAT REGISTER (GWA = F804h)

P(31:0)	FUNCTION
24	Set to 0.
23	Set to 0.
22	Set to 0.
21	Not used. Set to zero.
20:18	Input level detector floating point saturation level. Offsets the exponent to normalize the shift code. The ones-complement of these bits is added to the exponent bits from the input section to obtain the shift code, allowing the user to normalize the inputs to the same bit weights in the accumulators. For example, if the maximum expected exponent is 5 (101), programming this value into 20:18 causes 2 (010) to be added to the exponent normalizing it to a full scale shift code of 7. Set to 000 for fixed point inputs.
17	Enables the new (ISL5216) floating point modes; the 11-, 12-, 13- and 14-bit modes with 42dB of gain, and 15- and 16-bit modes with 18dB and 6dB ranges, respectively. The X-1 input must be used for 14-, 15- and 16-bit modes. See <i>Floating Point Input Mode Bit Mapping Tables</i> for details.
16	Floating point mode select bit 2. Used with GWA F804h, bits 8:7 to select the floating point mode/format. See <i>Floating Point Input Mode Bit Mapping Tables</i> for details.
15:13	Channel Input Source Selection. Selects as the data input for the level detector either A(15:0), B(15:0), C(15:0), D(15:0) or the $\mu$ P Test Input register as shown below.  <u>15:13 Source Selected</u> 000 A(15:0) 001 B(15:0) 010 C(15:0) 011 D(15:0) 100 $\mu$ P Test input register. This is provided for testing and to zero the input data bus when a channel is not in use. The Global Write Address register for the $\mu$ P Test input register is F807h.
12	$\mu$ P Register input enable select 1 = bit 11, 0 = one clock wide pulse on each write to location F808h. Select 0 to write data test data into the part. Select 1 to input a constant or to disable the input for minimum power dissipation when the input level detector section is unused.
11	$\mu$ P input enable. When bit 12 is set, this bit is the input enable for the $\mu$ P register input. Active low. 0=enabled, 1=disabled.
10	Parallel Data Input Format 0 Two's complement 1 Offset binary

TABLE 41. INPUT LEVEL DETECTOR SOURCE SELECT/FORMAT REGISTER (GWA = F804h) (Continued)

P(31:0)	FUNCTION
9	Fixed/Floating point 0 Fixed point 1 Floating point. The 17-bit input bus is divided into 11 to 16 mantissa bits and one to three exponent bits depending on bits 17, 16, 8 and 7. See <i>Floating Point Input Mode Bit Mapping Tables</i> for details.
8:7	Floating point mantissa size select bits 0 and 1. See <i>Floating Point Input Mode Bit Mapping Tables</i> for details.
6:4	De-multiplex control. These control bits are provided to demultiplex an input data stream comprised of a set of multiplexed data streams. Up to eight multiplexed data streams can be demultiplexed. These control bits select how many clocks after the $\overline{ENIx}$ signal to wait before taking the input sample. $\overline{ENIx}$ should be asserted for one clock period and aligned with the first channel of the multiplexed data set. For example, if four streams are multiplexed at half the clock rate, $\overline{ENIx}$ would align with the first clock period of the first stream, the second would start two clocks later, the next four clocks after $\overline{ENIx}$ , etc. The samples are aligned with $\overline{ENIx}$ (zero delay) at the input of the input level detector at the next $\overline{ENIx}$ . 000 zero delay 111 Seven clock periods of delay.
3	Interpolated/Gated Mode Select 0 Gated. The input level detector is updated once per clock when $\overline{ENIx}$ is asserted. 1 Interpolated. The input level detector is updated every clock. The input is zeroed when $\overline{ENIx}$ is high.
2:0	Unused. Set to 0.

TABLE 42. INPUT LEVEL DETECTOR CONFIGURATION REGISTER (GWA = F805h)

P(31:0)	FUNCTION
31:22	Set to zero.
21	1 Ones complement of 16-bit data after formatting. 0 Unmodified input.
20	1 Free run (ignore interval counter). 0 Stop when interval counter times out. This bit may also be set low temporarily when free running to stabilize the accumulator data for reading.
19:18	Input Level Detector Leak factor, A. 00 1 01 $2^{-8}$ 10 $2^{-12}$ 11 $2^{-16}$
17:16	Input Level Detector Mode 00 Leaky integrator ( $Y_n = A \cdot X_n + (1-A) \cdot Y_{n-1}$ , where A is the gain selected in bits 19:18). 01 Peak detector. 10 Integrator (bit 20 should be set to 0).
15:0	Input Level Detector Interval Load with two less than the desired number of input samples. The interval range is 2–65537 input samples.

TABLE 43. INPUT LEVEL DETECTOR START STROBE REGISTER (GWA = F806h)

P(15:0)	FUNCTION
N/A	Writing to this location clears the input level detector accumulator and restarts the interval counter. When the interval counter is done, bit 1 of the status word (direct register 3) is set.

TABLE 44.  $\mu$ P/TEST INPUT BUS REGISTER (GWA = F807h)

P(15:0)	FUNCTION
15:0	This 16-bit value can be used as the input to one or more NCO/Mixer/CIC sections or to the input level detector for test or to set the input to a constant value to minimize power when the channel is not in use. The $\overline{ENI}$ signal for this input is either bit 11 in the channel register at IWA *000h or the strobe generated by a write to location GWA F808h (selected via bit 12 of the channel register at IWA *000h).

TABLE 45.  $\mu$ P/TEST INPUT BUS  $\overline{\text{ENI}}$  REGISTER (GWA = F808h)

P(15:0)	FUNCTION
N/A	A write to this location, generates and $\overline{\text{ENI}}$ strobe for the $\mu$ P driven input port (when selected via bit 12 of IWA *000h).

TABLE 46. SYNCO STROBE REGISTER (GWA = F809h)

P(15:0)	FUNCTION
N/A	A write to this location will cause a one-clock-wide pulse on the SYNCO pin. The SYNCO pin is used to synchronize multiple channels or parts. The SYNCO pin from one part is typically connected to the SYNCI pin of all the parts. Up to two pipeline registers may be inserted in the SYNCO to SYNCI path.

TABLE 47. SYNCI STROBE REGISTER (GWA = F80Ah)

P(15:0)	FUNCTION
N/A	A write to this location generates a SYNCO pulse but also feeds it back to the SYNCI input.

TABLE 48. TEST CRC REGISTER (GWA = F80Bh)

P(15:0)	FUNCTION
15:0	Test CRC register. Load comparison signature into 15:0. Following a BIST test, the part returns its computed signature to 31:16.

TABLE 49.  $\mu$ P FIFO READ ORDER CONTROL REGISTER (GWA = F820h thru F83Fh)

P(15:0)	FUNCTION
4:0	The five bits selecting the data type are encoded as follows: C C D D D, where CC is the channel number and DDD is the data type. DDD                      Data Type 000    I(23:8)              The upper 16 bits of the I data path via the FIFO/AGC. 001    I(7:0),8*zeros        The lower 8 bits of the I data path. 010    Q(23:8)              The upper 16 bits of the Q data path via the FIFO/AGC. 011    Q(7:0),8*zero            The lower 8 bits of the Q data path. 100    Mag(23:8)              The upper 16 bits of magnitude (after the gain adjust described in channel register) 101    Mag(7:0),8*zero        The lower 8 bits of magnitude. 110    Phase(15:0)            The upper 16 bits of phase. 111    AGC gain (15:0)        The upper 16 bits of the AGC gain.

## Table of Indirect Read Address (IRA) Registers

The address decoding for the read source locations is given below. The internal address of the data to be read is written to direct address 3 (ADD(2:0) = 3) to select and/or fetch the data. A strobe is generated, if needed, to fetch or stabilize the data for reading. If a strobe is needed, the indirect read address must be written to direct address 3 each time the data is needed. If a strobe is not needed, the data can be read repeatedly at direct addresses 0 and 1 (ADD(2:0) = 0 and 1, respectively) with any changes in the data showing up

immediately. The strobe to sample the AGC gain is generated separately by an indirect write (see IWA \*00Fh in the *Tables of Indirect Write Address Registers*). This allows the AGC gain of all the channels to be sampled simultaneously. The indirect read address register is shared with indirect write address register, so a data verification read may be done immediately after a write without needing to write the register address to ADD(2:0) = 3 again.

NOTE: These Indirect Read Addresses are repeated for each channel. In the addresses below, the \* field is the channel select nibble. These bits of the Indirect Address select the target channel register for the data being read. Values of 0 through 3 and F are valid.

TABLE 50. TABLE OF INDIRECT READ ADDRESS (IRA) REGISTERS

IRA	BITS	FUNCTION
*000h	24:0	Channel Input Select / Format
*001h	15:0	PN Gain
*002h	15:0	CIC Decimation

TABLE 50. TABLE OF INDIRECT READ ADDRESS (IRA) REGISTERS

IRA	BITS	FUNCTION
*003h	5:0	CIC Destination FIR and Output Enable/Disable
*004h	19:0	Carrier NCO / CIC Control
*005h	31:0	Active Carrier NCO Center Frequency.
*007h	31:0	Timing NCO Frequency (upper 32 bits)
*008h	31:8	Timing NCO Frequency (lower 24 bits)
*00Ah	31:0	Filter Compute Engine / Resampler Control
*00Bh	13:0	Filter Start Offset
*00Ch	31:0	Wait Threshold / Decrement Value
*00Dh	8:0	Reset Write Pointer Offset
*00Eh	15:0	AGC gain load register (reads gain initially loaded into AGC gain register)
*00Fh	15:0	AGC gain read (must first write to AGC gain read strobe register IWA = *00Fh before reading)
*010h	31:0	AGC Loop Attack / Decay Gain Values
*011h	31:0	AGC Gain Limits
*012h	15:0	AGC Threshold
*013h	10:0	AGC / Discriminator Control

F805h	21:0	Input Level Detector Configuration
F806h	31:0	Input Level Detector result (valid when bit 1 of status word is set)
F807h	15:0	μP / Test Input Bus
F80Bh	31:0	BIST
F820h - F83Fh	4:0	μP FIFO Read Order Control

**Absolute Maximum Ratings**

Supply Voltage	4.6V
Core Supply Voltage	3.5V
Input, Output or I/O Voltage	GND -0.5V to $V_{CC} + 0.5V$
ESD Classification	Class I

**Operating Conditions**

Voltage Range (I/O)	+3.135V to +3.465V
Voltage Range (core)	+2.375V to +2.625V
Temperature Range	
Industrial	-40°C to +85°C
Input Low Voltage	0V to +0.8V
Input High Voltage	.2V to I/O $V_{CC}$

**CAUTION:** Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied

**NOTE:**

21.  $\theta_{JA}$  is measured with the component mounted on a high effective thermal conductivity test board in free air or with the airflow. See Tech Brief TB379 for details.

**Thermal Information**

Thermal Resistance (Typical)	$\theta_{JA}$ (°C/W)
196 Lead BGA Package (0.8 mm pitch)	30
w/200 LFM Air Flow	27
w/400 LFM Air Flow	26
196 Lead BGA Package (1.0 mm pitch)	29
w/200 LFM Air Flow	26
w/400 LFM Air Flow	25
Maximum Junction Temperature	150°C
Maximum Storage Temperature Range	-65°C to 150°C
Maximum Lead Temperature (Soldering 10s)	300°C

**Electrical Specifications**  $V_{CC1}$  = Core Supply: 2.5V  $\pm$  0.125V,  $V_{CC2}$  = I/O Supply: 3.3  $\pm$  0.165V,  $T_A$  = -40°C to 85°C, Industrial

PARAMETER	SYMBOL	TEST CONDITIONS	MIN	TYP	MAX	UNITS
Logical One Input Voltage	$V_{IH}$	$V_{CC2} = 3.465V$	2.0	-	-	V
Logical Zero Input Voltage	$V_{IL}$	$V_{CC2} = 3.135V$	-	-	0.8	V
Output High Voltage	$V_{OH}$	$I_{OH} = -2mA, V_{CC2} = 3.135V$	2.6	-	-	V
Output Low Voltage	$V_{OL}$	$I_{OL} = 2mA, V_{CC2} = 3.135V$	-	-	0.4	V
Input Leakage Current	$I_I$	$V_{IN} = V_{CC2}$ or GND, $V_{CC2} = 3.465V$	-10	-	10	$\mu A$
Output Leakage Current	$I_O$	$V_{IN} = V_{CC2}$ or GND, $V_{CC2} = 3.465V$	-10	-	10	$\mu A$
Typical Leakage Current	$I_{O-TYP}$	$V_{IN} = V_{CC2}$ or GND, $V_{CC2} = 3.465V$	-	$\pm 2$	-	$\mu A$
Standby Power Supply Current -- Core	$I_{CCSB-CR}$	$V_{CC1} = 2.625V$ , Outputs Not Loaded, No CLK	-	-	8	mA
Standby Power Supply Current -- IO's	$I_{CCSB-IO}$	$V_{CC1} = 2.625V$ , Outputs Not Loaded, No CLK	-	-	0.5	mA
Operating Power Supply Current -- Core	$I_{CCOP-CR}$	$f = 80MHz, V_{IN} = V_{CC1}$ or GND, $V_{CC1} = 2.625V, C_L = 40pF$	-	-	700	mA
Operating Power Supply Current -- IO's	$I_{CCOP-IO}$	$f = 80MHz, V_{IN} = V_{CC1}$ or GND, $V_{CC1} = 2.625V, C_L = 40pF$	-	-	50	mA
Operating Power Supply Current -- Typical	$I_{CCOP-TYP}$	$f = 80MHz, V_{IN} = V_{CC1}$ or GND, $V_{CC1} = 2.625V, C_L = 40pF$	-	570	-	mA (Note 22)
Input Capacitance	$C_{IN}$	Freq = 1MHz, $V_{CC}$ open, all measurements are referenced to device ground	-	-	5	pF (Note 23)
Output Capacitance	$C_{OUT}$		-	-	5	pF (Note 23)

**NOTES:**

22. Power Supply current is proportional to frequency of operation and programmed configuration of the part. Typical rating for  $I_{CCOP}$  is 7.125mA/MHz @ 80MHz, full utilization.
23. Capacitance:  $T_A = 25^\circ C$ , controlled via design or process parameters and not directly tested. Characterized upon initial design and at major process or design changes.

**Electrical Specifications**  $V_{CC1}$  = Core Supply:  $2.5V \pm 0.125V$ ,  $V_{CC2}$  = I/O Supply:  $3.3 \pm 0.165V$ ,  
 $T_A$  = -40°C to 85°C Industrial

NOTES:

26. Decimating Halfband Filter #4 Coefficients are shown for reference only. If it is desired to implement this FIR filter, these coefficients would have to be loaded into the FIR Coefficient RAM (They are not included in the ROMd Fir Filter Coefficient memory).
27. The 22-bit ROMd FIR filter coefficients are located in the upper 22 bits of the Read register when read back from ROM memory (except for Halfband #4). These bits occupy the upper six bytes (24 bits) with the two LSBs of the lower byte (bits 9:8 of 31:0) being zero. The decimal value for the hexadecimal coefficient is calculated by first converting the hexadecimal value to decimal and the dividing by  $2^{23}$  (8388608).

## NOTE:

29. The 22-bit ROMd FIR filter coefficients are located in the upper 22 bits of the Read register when read back from ROM memory. These bits occupy the upper three bytes (24 bits) with the two LSBs of the lower byte (bits 9:8 of 31:0) being zero. The decimal value for the hexadecimal coefficient is calculated by first converting the hexadecimal value to decimal and the dividing by  $2^{23}$  (8388608).

## Appendix A - Changes from HSP50216

The ISL5216 is pin and register compatible with the HSP50216 facilitating an easy migration to the ISL5216 from previous designs. Certain changes to hardware and possibly software will be required to make this transition, however.

The listing below details the changes that should be considered.

### Pinout Changes

Thirteen previously no-connect pins have been assigned to ISL5216 features. These are five JTAG pins (TDI, TDO,

TCLK, TMS, and TRST), four additional exponent bits (one for each input bus: Am1, Bm1, Cm1 and Dm1), and four additional channel-specific SYNCI inputs (SYNCI0, SYNCI1, SYNCI2, and SYNCI3). All new input pins have weak pull-ups / pull-downs to allow them to be left floating if not used.

In addition to the newly-assigned pins, some of the 3.3V VCC lines of the HSP50216 have been changed to 2.5V on the ISL5216. The ISL5216 now has VCC1 (2.5V core supply pins) and VCC2 (3.3V for I/O pads).

See pin descriptions for additional information.

## Feature Changes

1. Core voltage lowered from 3.3V to 2.5V for lower power operation (I/O supply voltage remains at 3.3V). Maximum speed increased from 70MHz to 80MHz.
2. Added JTAG boundary scan test pins.
3. Added readback capability to all the control registers. See Table of Indirect Read Address Registers for complete listing. Also added filter compute engine data RAM read / write test mode via microprocessor interface (**F800H** bit 15).
4. Added SYNCI0, SYNCI1, SYNCI2 and SYNCI3 pins to serve as SYNCI for individual channels. These inputs are OR'd together with the original (HSP50216) SYNCI so that SYNCI still functions as a global input.
5. Added GWA register **F80AH** to generate a SYNCO as in F809H, but which is also internally fed back to SYNCI.
6. Added more CIC barrel shifter range. Maximum shift range was increased by 16 from 31 (HSP50216) to 47, allowing for unit gain at lower CIC decimations and CIC bypassing (see CIC Filter section for restrictions). This added bit 19 to IWA **\*004H**.
7. Added additional input pins for 14/3, 15/2 and 16/1 floating point input modes. Also added an additional 6dB to the old 14/2 mode. This added bits 20:16 to IWA **\*000H** and 20:16 to GWA **F804H** (input level detector).
8. Added a complex input mode. In this mode, complex (I and Q) data can be multiplexed with the I input first and Q input second. The  $\overline{\text{EN}}_i$  signal indicates the clock cycle when I is valid, and the Q data is taken on either the next input clock or the one two clocks after I. This added bits 24:22 to IWA **\*000H** and 24:22 to GWA **F804H**. Complex input mode is not valid for the input level detector (only I samples are processed).
9. Added a programmable delay to the sin / cos path to correct for misalignment between the input data enables and the NCO enables when input samples are unevenly spaced in the gated input mode. This added bit 21 to IWA **\*000H**. If set, the misalignment is corrected. Can be set to 0 to retain HSP50216 behavior.
10. Increased carrier phase offset resolution from 3 to 16 bits. The original 3 bits (**\*004H** bits 8:6) are added to a 16 bit value loaded into new IWA register **\*01CH**. Register **\*01CH** is zeroed by the reset pin.
11. Changed microprocessor FIFO read decoding to remove the  $\overline{\text{CE}}$  to  $\overline{\text{RD}}$  timing constraint ( $\mu\text{Pmode} = 0$ ). For  $\mu\text{Pmode} = 1$  the constraint was from  $\overline{\text{ADDx}}$ ,  $\overline{\text{CE}}$  and  $\overline{\text{R}\overline{\text{W}}}$  set up to the falling edge of  $\overline{\text{DSTRB}}$ .
12. Changed serial output control logic to allow as few as five clocks between output samples rather than the minimum of seven clocks between inputs to the serial output section required by the HSP50216.
13. Fixed the delay mode issue in the serial output control logic (in the HSP50216, if delayed samples extended to within seven samples of the new input to the serial output section the last sample could be dropped).
14. Fixed a problem in the timing NCO circuit that, under certain circumstances, could cause lost samples or no output.
15. Added BIST (built-in self test).
16. Added a reset of the CIC's comb data registers on a front end reset. This reduces the transient due to old data in the comb when the decimation counters restart.
17. Changed filter routing path 3. In HSP50216 path 3 routed intermediate filter calculations both to the filter compute engine input and directly to I2 and Q2 outputs. In the ISL5216, path 3 routes data from the filter compute engine output through the FIFO and AGC to I2 and Q2. See *Back End Data Routing* figure.
18. Changed the mask revision field in the status register to 3. The HSP50216 rev. C reported a value of 2.
19. Changed Timing and Carrier NCO frequency readback register locations. On the HSP50216, Carrier NCO frequency readback was at IRA **\*006H**. This has changed to **\*005H** on the ISL5216. Likewise Timing NCO frequency readback has changed from IRA **\*009H** (for the upper 32 bits) on the HSP50216 to **\*007H** for the upper 32 bits and **\*008H** for the lower 24 bits. See *Table of Indirect Read Address Registers* for complete listing of readback registers.
20. Removed bits 20:17 from GWA register **F800H** (test control register). Bit 0 no longer needs to be set to route bits 31:21 to their corresponding output pins (see bit 16 description).

All new control bits are inactive if set to zero for backward compatibility with HSP50216 software.

## Power-up Sequencing

The ISL5216 core and I/O blocks are isolated by structures which may become forward biased if the supply voltages are not at specified levels. During the power-up and power-down operations, differences in the starting point and ramp rates of the two supplies may cause current to flow in the isolation structures which, when prolonged and excessive, can reduce the usable life of the device.

In general, the most preferred case would be to power-up the core and I/O structures simultaneously. However, it is also safe to power-up the core prior to the I/O block if simultaneous application of the supplies is not possible. In this case, the I/O voltage should be applied in 10ms to 100ms nominally to preserve supply component reliability. Bringing the core and I/O supplies to their respective regulation levels in a maximum time frame of a 100ms, moderates the stresses placed on both, the power supply and the ISL5216.

aaa	0.005		0.12		-

Rev. 2 12/00

**NOTES:**

1. Controlling dimension: MILLIMETER. Converted inch dimensions are not necessarily exact.
2. Dimensioning and tolerancing conform to ASME Y14.5M-1994.
3. "MD" and "ME" are the maximum ball matrix size for the "D" and "E" dimensions, respectively.
4. "N" is the maximum number of balls for the specific array size.
5. Primary datum C and seating plane are defined by the spherical crowns of the contact balls.
6. Dimension "A" includes standoff height "A1", package body thickness and lid or cap height "A2".
7. Dimension "b" is measured at the maximum ball diameter, parallel to the primary datum C.
8. Pin "A1" is marked on the top and bottom sides adjacent to A1.
9. "S" is measured with respect to datum's A and B and defines the position of the solder balls nearest to package centerlines. When there is an even number of balls in the outer row the value is "S" = e/2.

V196.15x15 package information available on Intersil's website.
