

## 13-Bit Differential Input, Low Power A/D Converter with SPI™ Serial Interface

### Features

- Full Differential Inputs
- $\pm 1$  LSB max DNL
- $\pm 1$  LSB max INL (MCP3301-B)
- $\pm 2$  LSB max INL (MCP3301-C)
- Single supply operation: 2.7V to 5.5V
- 100 ksp/s sampling rate with 5V supply voltage
- 50 ksp/s sampling rate with 2.7V supply voltage
- 50 nA typical standby current, 1  $\mu$ A max
- 450  $\mu$ A max active current at 5V
- Industrial temp range: -40°C to +85 °C
- 8-pin MSOP, PDIP and SOIC packages
- MXDEV™ Evaluation kit available

### Applications

- Remote Sensors
- Battery Operated Systems
- Transducer Interface

### Package Types

### General Description

The Microchip Technology Inc. MCP3301 13-bit A/D converter features full differential inputs and low power consumption in a small package that is ideal for battery powered systems and remote data acquisition applications.

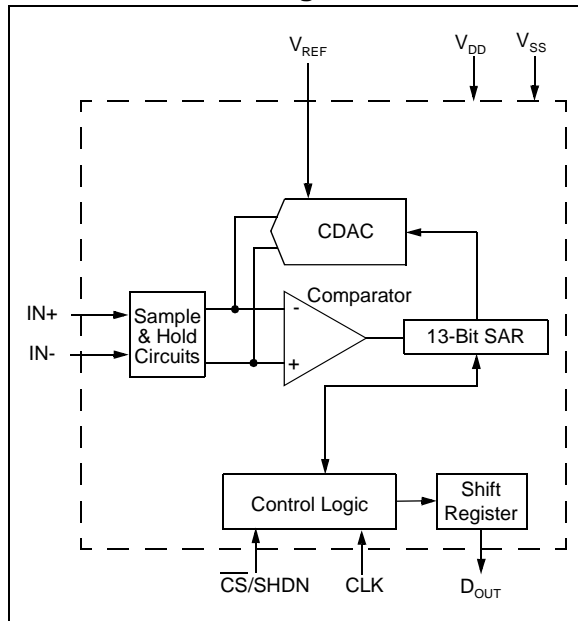

Incorporating a successive approximation architecture with on-board sample and hold circuitry, this 13-bit A/D converter is specified to have  $\pm 1$  LSB Differential Nonlinearity (DNL) and  $\pm 1$  LSB Integral Nonlinearity (INL) for B-grade devices and  $\pm 2$  LSB for C-grade devices. The industry-standard SPI™ serial interface enables 13-bit A/D converter capability to be added to any PIC® microcontroller.

The MCP3301 features a low current design that permits operation with typical standby and active currents of only 50 nA and 300  $\mu$ A, respectively. The device operates over a broad voltage range of 2.7V to 5.5V and is capable of conversion rates of up to 100 ksp/s. The reference voltage can be varied from 400 mV to 5V, yielding input-referred resolution between 98  $\mu$ V and 1.22 mV.

The MCP3301 is available in 8-pin PDIP, 150 mil SOIC and MSOP packages. The full differential inputs of this device enable a wide variety of signals to be used in applications such as remote data acquisition, portable instrumentation and battery operated applications.

# MCP3301

## Functional Block Diagram

## 1.0 ELECTRICAL CHARACTERISTICS

### Maximum Ratings\*

$V_{DD}$  ..... 7.0V  
 All inputs and outputs w.r.t.  $V_{SS}$  ..... -0.3V to  $V_{DD} + 0.3V$   
 Storage temperature ..... -65°C to +150°C  
 Ambient temp. with power applied ..... -65°C to +125°C  
 Maximum Junction Temperature ..... 150°C  
 ESD protection on all pins (HBM) ..... > 4 kV

\***Notice:** Stresses above those listed under "Maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

## PIN FUNCTION TABLE

Name	Function
$V_{REF}$	Reference Voltage Input
IN(+)	Positive Analog Input
IN(-)	Negative Analog Input
$V_{SS}$	Ground
$\overline{CS}/SHDN$	Chip Select / Shutdown Input
$D_{OUT}$	Serial Data Out
CLK	Serial Clock
$V_{DD}$	+2.7V to 5.5V Power Supply

## ELECTRICAL SPECIFICATIONS

<b>Electrical Characteristics:</b> Unless otherwise noted, all parameters apply at $V_{DD} = 5V$ , $V_{SS} = 0V$ , and $V_{REF} = 5V$ . Full differential input configuration (Figure 3-4) with fixed common mode voltage of 2.5V. All parameters apply over temperature with $T_{AMB} = -40^{\circ}C$ to $+85^{\circ}C$ ( <b>Note 7</b> ). Conversion speed ( $f_{SAMPLE}$ ) is 100 kpsps with $f_{CLK} = 17 * f_{SAMPLE}$						
Parameter	Symbol	Min	Typ	Max	Units	Conditions
<b>Conversion Rate</b>

## 4.0 PIN DESCRIPTIONS

The descriptions of the pins are listed in Table 4-1.

**TABLE 4-1: PIN FUNCTION TABLE.**

Name	Function
V <sub>REF</sub>	Reference Voltage Input
IN(+)	Positive Analog Input
IN(-)	Negative Analog Input
V <sub>SS</sub>	Ground
CS/SHDN	Chip Select / Shutdown Input
D <sub>OUT</sub>	Serial Data Out
CLK	Serial Clock
V <sub>DD</sub>	+2.7V to 5.5V Power Supply

### 4.1 Voltage Reference (V<sub>REF</sub>)

This input pin provides the reference voltage for the device, which determines the maximum range of the analog input signal and the LSB size.

The LSB size is determined by the equation shown below. As the reference input is reduced, the LSB size is reduced accordingly.

#### EQUATION

$$\text{LSB Size} = \frac{2 \times V_{\text{REF}}}{8192}$$

When using an external voltage reference device, the system designer should always refer to the manufacturer's recommendations for circuit layout. Any instability in the operation of the reference device will have a direct effect on the accuracy of the ADC conversion results.

### 4.2 IN(+)

Positive analog input. This pin has an absolute voltage range of V<sub>SS</sub>-0.3V to V<sub>DD</sub>+0.3V. The full scale input range is defined as the absolute value of (IN+) - (IN-).

### 4.3 IN(-)

Negative analog input. This pin has an absolute voltage range of V<sub>SS</sub>-0.3V to V<sub>DD</sub>+0.3V. The full scale input range is defined as the absolute value of (IN+) - (IN-).

### 4.4 V<sub>SS</sub>

Ground connection to internal circuitry. If an analog ground plane is available, it is recommended that this device be tied to the analog ground plane in the circuit. See Section 6.6, "Layout Considerations", for more information regarding circuit layout.

### 4.5 Chip Select/Shutdown ( $\overline{\text{CS}}$ /SHDN)

The  $\overline{\text{CS}}$ /SHDN pin is used to initiate communication with the device when pulled low. This pin will end a conversion and put the device in low power standby when pulled high. The  $\overline{\text{CS}}$ /SHDN pin must be pulled high between conversions and cannot be tied low for multiple conversions. See Figure 7-2 for serial communication protocol.

### 4.6 Serial Data Output (D<sub>OUT</sub>)

The SPI serial data output pin is used to shift out the results of the A/D conversion. Data will always change on the falling edge of each clock as the conversion takes place. See Figure 7-2 for serial communication protocol.

### 4.7 Serial Clock (CLK)

The SPI clock pin is used to initiate a conversion as well as to clock out each bit of the conversion as it takes place. See Section 6.2 for constraints on clock speed and Figure 7-2 for serial communication protocol.

### 4.8 V<sub>DD</sub>

The voltage on this pin can range from 2.7 to 5.5V. To ensure accuracy, a 0.1 μF ceramic bypass capacitor should be placed as close as possible to the pin. See Section 6.6 for more information regarding circuit layout.

## 5.0 DEFINITION OF TERMS

**Bipolar Operation** - This applies to either a differential or single ended input configuration, where both positive and negative codes are output from the A/D converter. Full bipolar range includes all 8192 codes. For bipolar operation on a single ended input signal, the A/D converter must be configured to operate in pseudo differential mode.

**Unipolar Operation** - This applies to either a single ended or differential input signal where only one side of the device transfer is being used. This could be either the positive or negative side, depending on which input (IN+ or IN-) is being used for the DC bias. Full unipolar operation is equivalent to a 12-bit converter.

**Full Differential Operation** - Applying a full differential signal to both the IN(+) and IN(-) inputs is referred to as *full differential operation*. This configuration is described in Figure 3-4.

**Pseudo-Differential Operation** - Applying a single ended signal to only one of the input channels with a bipolar output is referred to as *pseudo differential operation*. To obtain a bipolar output from a single ended input signal the inverting input of the A/D converter must be biased above  $V_{SS}$ . This operation is described in Figure 3-5.

**Integral Nonlinearity** - The maximum deviation from a straight line passing through the endpoints of the bipolar transfer function is defined as the maximum *integral nonlinearity* error. The endpoints of the transfer function are a point 1/2 LSB above the first code transition (0x1000) and 1/2 LSB below the last code transition (0x0FFF).

**Differential Nonlinearity** - The difference between two measured adjacent code transitions and the 1 LSB ideal is defined as *differential nonlinearity*.

**Positive Gain Error** - This is the deviation between the last positive code transition (0x0FFF) and the ideal voltage level of  $V_{REF}-1/2$  LSB, after the bipolar offset error has been adjusted out.

**Negative Gain Error** - This is the deviation between the last negative code transition (0x1000) and the ideal voltage level of  $-V_{REF}-1/2$  LSB, after the bipolar offset error has been adjusted out.

**Offset Error** - This is the deviation between the first positive code transition (0x0001) and the ideal 1/2 LSB voltage level.

**Acquisition Time** - The *acquisition time* is defined as the time during which the internal sample capacitor is charging. This occurs for 1.5 clock cycles of the external CLK as defined in Figure 7-2.

**Conversion Time** - The *conversion time* occurs immediately after the *acquisition time*. During this time, successive approximation of the input signal occurs as the 13-bit result is being calculated by the internal circuitry. This occurs for 13 clock cycles of the external CLK as defined in Figure 7-2.

**Signal to Noise Ratio** - *Signal to Noise Ratio (SNR)* is defined as the ratio of the signal to noise measured at the output of the converter. The signal is defined as the rms amplitude of the fundamental frequency of the input signal. The noise value is dependant on the device noise as well as the quantization error of the converter and is directly affected by the number of bits in the converter. The *theoretical* signal to noise ratio limit based on quantization error only for an N-bit converter is defined as:

### EQUATION

$$SNR = (6.02N + 1.76)dB$$

For a 13-bit converter, the theoretical SNR limit is 80.02 dB.

**Total Harmonic Distortion** - *Total Harmonic Distortion (THD)* is the ratio of the rms sum of the harmonics to the fundamental, measured at the output of the converter. For the MCP3301, it is defined using the first 9 harmonics, as shown in the following equation:

### EQUATION

$$THD(-dB) = -20 \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + \dots + V_8^2 + V_9^2}}{V_1}$$

Here  $V_1$  is the rms amplitude of the fundamental and  $V_2$  through  $V_9$  are the rms amplitudes of the second through ninth harmonics.

**Signal to Noise plus Distortion (SINAD)** - Numerically defined, *SINAD* is the calculated combination of SNR and THD. This number represents the dynamic performance of the converter, including any harmonic distortion.

### EQUATION

$$SINAD(dB) = 20 \log \sqrt{10^{(SNR/10)} + 10^{-(THD/10)}}$$

**Effective Number of Bits** - *Effective Number of Bits (ENOB)* states the relative performance of the ADC in terms of its resolution. This term is directly related to SINAD by the following equation:

### EQUATION

$$ENOB(N) = \frac{SINAD - 1.76}{6.02}$$

For SINAD performance of 78 dB, the effective number of bits is 12.66.

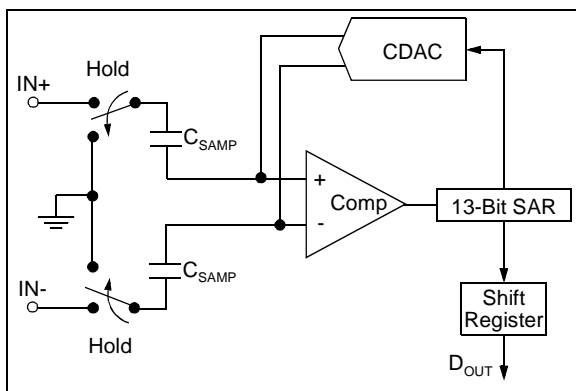

**Spurious Free Dynamic Range** - *Spurious Free Dynamic Range (SFDR)* is the ratio of the rms value of the fundamental to the next largest component in ADC's output spectrum. This is, typically, the first harmonic, but could also be a noise peak.

# MCP3301

## 6.0 APPLICATIONS INFORMATION

### 6.1 Conversion Description

The MCP3301 A/D converter employs a conventional SAR architecture. With this architecture, the potential between the IN+ and IN- inputs are simultaneously sampled and stored with the internal sample circuits for 1.5 clock cycles ( $t_{ACQ}$ ). Following this sample time, the input hold switches of the converter open and the device uses the collected charge to produce a serial 13-bit binary two's complement output code. This conversion process is driven by the external clock and must include 13 clock cycles, one for each bit. During this process, the most significant bit (MSB) is output first. This bit is the sign bit and indicates if the IN+ or IN- input is at a higher potential.

**FIGURE 6-1:** Simplified Block Diagram.

### 6.2 Driving the Analog Input

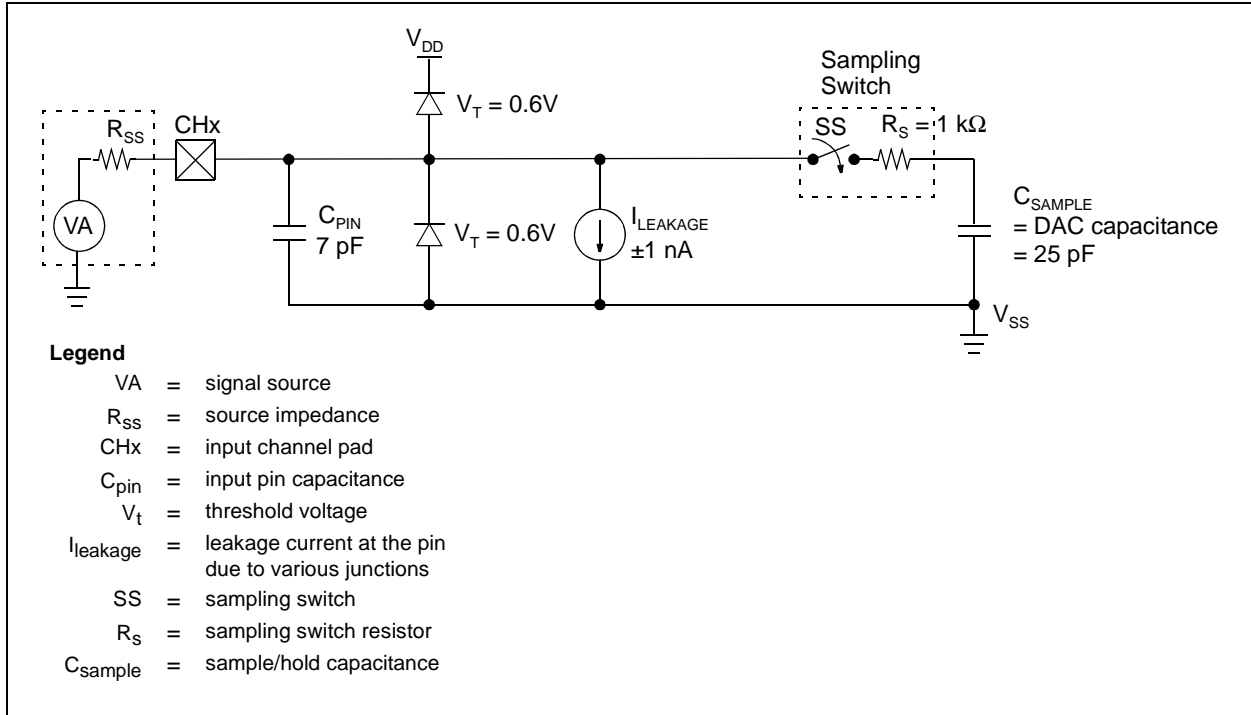

The analog input of the MCP3301 is easily driven either differentially or single-ended. Any signal that is common to the two input channels will be rejected by the common mode rejection of the device. During the charging time of the sample capacitor, a small charging current will be required. For low source impedances, this input can be driven directly. For larger source impedances, a larger acquisition time will be required due to the RC time constant that includes the source impedance. For the A/D Converter to meet specification, the charge holding capacitor ( $C_{SAMPLE}$ ) must be given enough time to acquire a 13-bit accurate voltage level during the 1.5 clock cycle acquisition period.

An analog input model is shown in Figure 6-3. This model is accurate for an analog input, regardless if it is configured as a single-ended input or the IN+ and IN- input in differential mode. In this diagram, it is shown that the source impedance ( $R_S$ ) adds to the internal sampling switch ( $R_{SS}$ ) impedance, directly affecting the time that is required to charge the capacitor ( $C_{SAMPLE}$ ). Consequently, a larger source impedance with no additional acquisition time increases the offset, gain and integral linearity errors of the conversion. To overcome this, a slower clock speed can be used to allow for the longer charging time. Figure 6-2 shows the maximum clock speed associated with source impedances.

**FIGURE 6-2:** Maximum Clock Frequency vs. Source Resistance ( $R_{SS}$ ) to maintain  $\pm 1$  LSB INL.

**FIGURE 6-3:** Analog Input Model.

## 6.2.1 MAINTAINING MINIMUM CLOCK SPEED

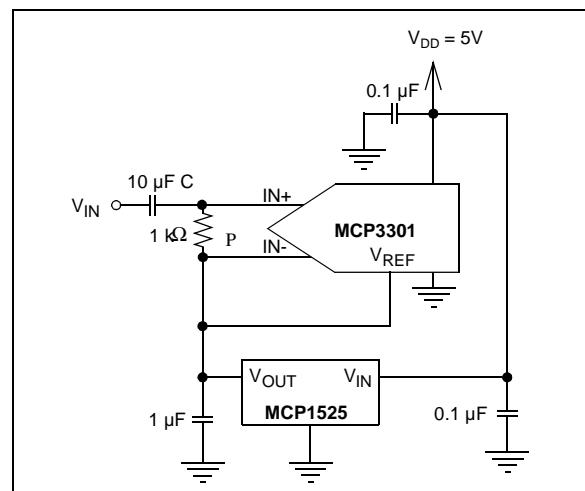

When the MCP3301 initiates, charge is stored on the sample capacitor. When the sample period is complete, the device converts one bit for each clock that is received. It is important for the user to note that a slow clock rate will allow charge to bleed off the sample capacitor while the conversion is taking place. For the MCP330X devices, the recommended minimum clock speed during the conversion cycle ( $t_{CONV}$ ) is 85 kHz. Failure to meet this criteria may introduce linearity errors into the conversion outside the rated specifications. It should be noted that, during the entire conversion cycle, the A/D converter does not have requirements for clock speed or duty cycle as long as all timing specifications are met.

## 6.3 Biasing Solutions

For pseudo-differential bipolar operation, the biasing circuit shown in Figure 6-4 shows a single-ended input AC coupled to the converter. This configuration will give a digital output range of -4096 to +4095. With the 2.5V reference, the LSB size is equal to 610  $\mu$ V.

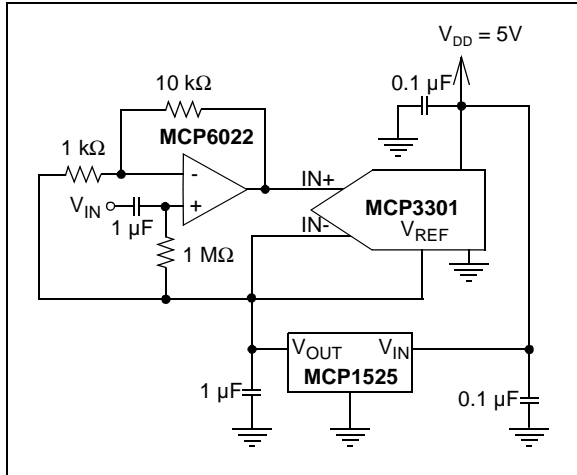

Although the ADC is not production tested with a 2.5V reference as shown, linearity will not change more than 0.1 LSB. See Figure 2-2 and 2-9 for DNL and INL errors versus  $V_{REF}$  at  $V_{DD} = 5V$ . A trade-off exists between the high pass corner and the acquisition time. The value of C will need to be quite large in order to bring down the high pass corner. The value of R needs to be 1 k $\Omega$  or less, since higher input impedances

require additional acquisition time. Using the values in Figure 6-4, we have a 100 Hz corner frequency. See Figure 2-12 for the relationship between input impedance and acquisition time.

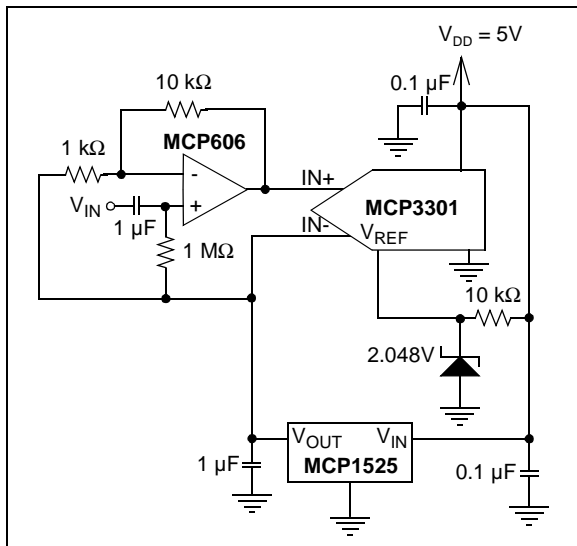

**FIGURE 6-4:** Pseudo-differential biasing circuit for bipolar operation.

Using an external operational amplifier on the input allows for gain and buffers the input signal from the input to the ADC, allowing for a higher source impedance. This circuit is shown in Figure 6-5.

**FIGURE 6-5:** Adding an amplifier allows for gain and also buffers the input from any high impedance sources.

This circuit shows that some headroom will be lost due to the amplifier output not being able to swing all the way to the rail. An example would be for an output swing of 0V to 5V. This limitation can be overcome by supplying a  $V_{REF}$  that is slightly less than the common mode voltage. Using a 2.048V reference for the A/D converter, while biasing the input signal at 2.5V solves the problem. This circuit is shown in Figure 6-6.

**FIGURE 6-6:** Circuit solution to overcome amplifier output swing limitation.

## 6.4 Common Mode Input Range

The common mode input range has no restriction and is equal to the absolute input voltage range:  $V_{SS} - 0.3V$  to  $V_{DD} + 0.3V$ . However, for a given  $V_{REF}$ , the common mode voltage has a limited swing if the entire range of the A/D converter is to be used. Figure 6-7 and Figure 6-8 show the relationship between  $V_{REF}$  and the common mode voltage. A smaller  $V_{REF}$  allows for wider flexibility in a common mode voltage.  $V_{REF}$  levels down to 400 mV and exhibits less than 0.1 LSB change in DNL and INL. See Figure 2-9 and Figure 2-12 for characterization graphs that illustrate this performance relationship.

**FIGURE 6-7:** Common Mode Range of Full Differential input signal versus  $V_{REF}$ .

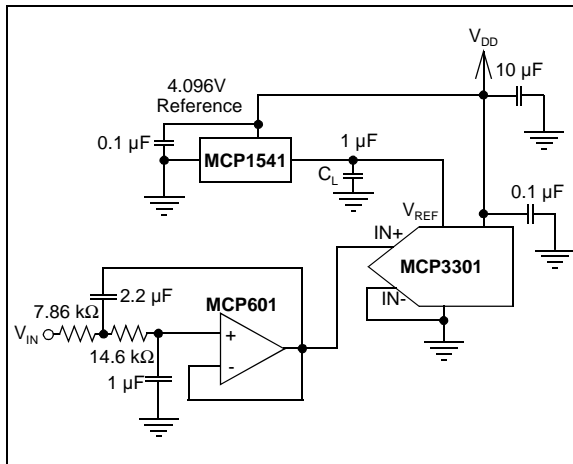

**FIGURE 6-8:** Common Mode Range versus  $V_{REF}$  for Pseudo Differential Input.

## 6.5 Buffering/Filtering the Analog Inputs

Inaccurate conversion results may occur if the signal source for the A/D converter is not a low impedance source. Buffering the input will solve the impedance issue. It is also recommended that an analog filter be used to eliminate any signals that may be aliased back into the conversion results. Using an op amp to drive the analog input of the MCP3301 is illustrated in Figure 6-9. This amplifier provides a low impedance source for the converter input and low pass filter, which eliminates unwanted high frequency noise. Values shown are for a 10 Hz Butterworth Low pass filter.

Low pass (anti-aliasing) filters can be designed using Microchip's interactive FilterLab<sup>®</sup> software. FilterLab will calculate capacitor and resistor values as well as determine the number of poles that are required for the application. For more information on filtering signals, see AN-699 "Anti-Aliasing Analog Filters for Data Acquisition Systems".

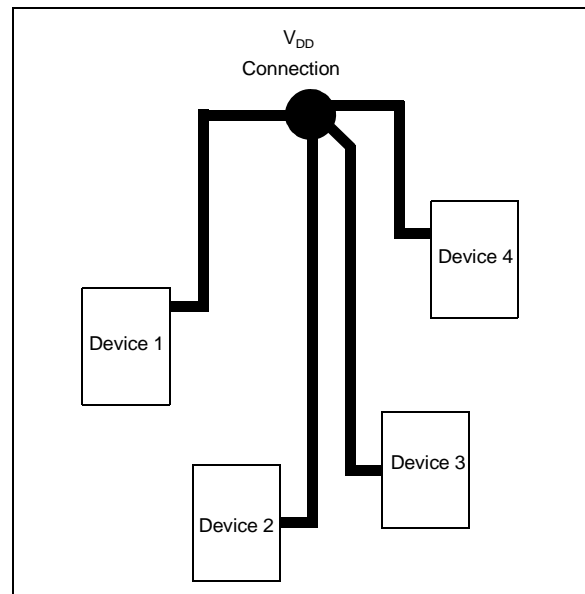

**FIGURE 6-9:** The MCP601 Operational Amplifier is used to implement a 2nd order anti-aliasing filter for the signal being converted by the MCP3301.

## 6.6 Layout Considerations

When laying out a printed circuit board for use with analog components, care should be taken to reduce noise wherever possible. A bypass capacitor from  $V_{DD}$  to ground should always be used with this device and should be placed as close as possible to the device pin. A bypass capacitor value of 0.1  $\mu\text{F}$  is recommended.

Digital and analog traces should be separated as much as possible on the board with no traces running underneath the device or bypass capacitor. Extra precautions should be taken to keep traces with high frequency signals (such as clock lines) as far as possible from analog traces.

Use of an analog ground plane is recommended in order to keep the ground potential the same for all devices on the board. Providing  $V_{DD}$  connections to devices in a "star" configuration can also reduce noise by eliminating current return paths and associated errors (Figure 6-10). For more information on layout tips when using the MCP3301 or other ADC devices, refer to AN-688 "Layout Tips for 12-Bit A/D Converter Applications".

**FIGURE 6-10:**  $V_{DD}$  traces arranged in a 'Star' configuration in order to reduce errors caused by current return paths.

# MCP3301

## 7.0 SERIAL COMMUNICATIONS

### 7.1 Output Code Format

The output code format is a binary two's complement scheme with a leading sign bit that indicates the sign of the output. If the IN+ input is higher than the IN- input, the sign bit will be a zero. If the IN- input is higher, the sign bit will be a '1'.

The diagram shown in Figure 7-1 shows the output code transfer function. In this diagram, the horizontal axis is the analog input voltage and the vertical axis is the output code of the ADC. It shows that when IN+ is equal to IN-, both the sign bit and the data word are zero. As IN+ gets larger, with respect to IN-, the sign bit is a zero and the data word gets larger. The full scale output code is reached at +4095 when the input [(IN+) - (IN-)] reaches  $V_{REF} - 1$  LSB. When IN- is larger than IN+, the two's complement output codes will be seen with the sign bit being a one. Some examples of analog input levels and corresponding output codes are shown in Table 7-1

TABLE 7-1: BINARY TWO'S COMPLEMENT OUTPUT CODE EXAMPLES.

Analog Input Levels	Sign Bit	Binary Data	Decimal DATA
Full Scale Positive (IN+)-(IN-) = $V_{REF}-1$ LSB	0	1111 1111 1111	+4095
(IN+)-(IN-) = $V_{REF}-2$ LSB	0	1111 1111 1110	+4094
IN+ = (IN-) +2 LSB	0	0000 0000 0010	+2
IN+ = (IN-) +1 LSB	0	0000 0000 0001	+1
IN+ = IN-	0	0000 0000 0000	0
IN+ = (IN-) - 1 LSB	1	1111 1111 1111	-1
IN+ = (IN-) - 2 LSB	1	1111 1111 1110	-2
(IN+)-(IN-) = $V_{REF}-2$ LSB	1	0000 0000 0001	-4095
Full Scale Negative (IN+)-(IN-) = $V_{REF}-1$ LSB	1	0000 0000 0000	-4096

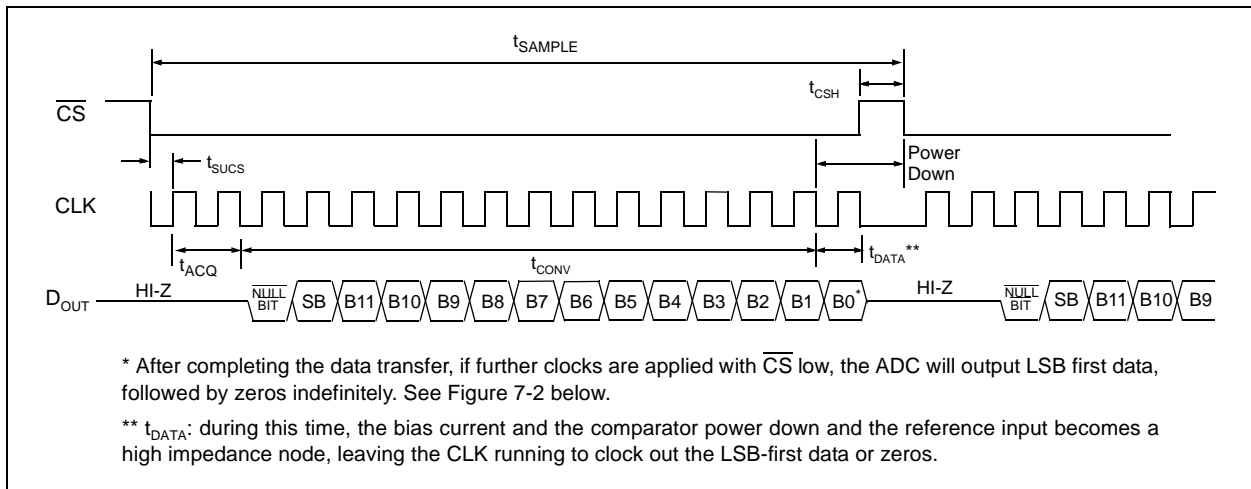

FIGURE 7-1: Output Code Transfer Function.

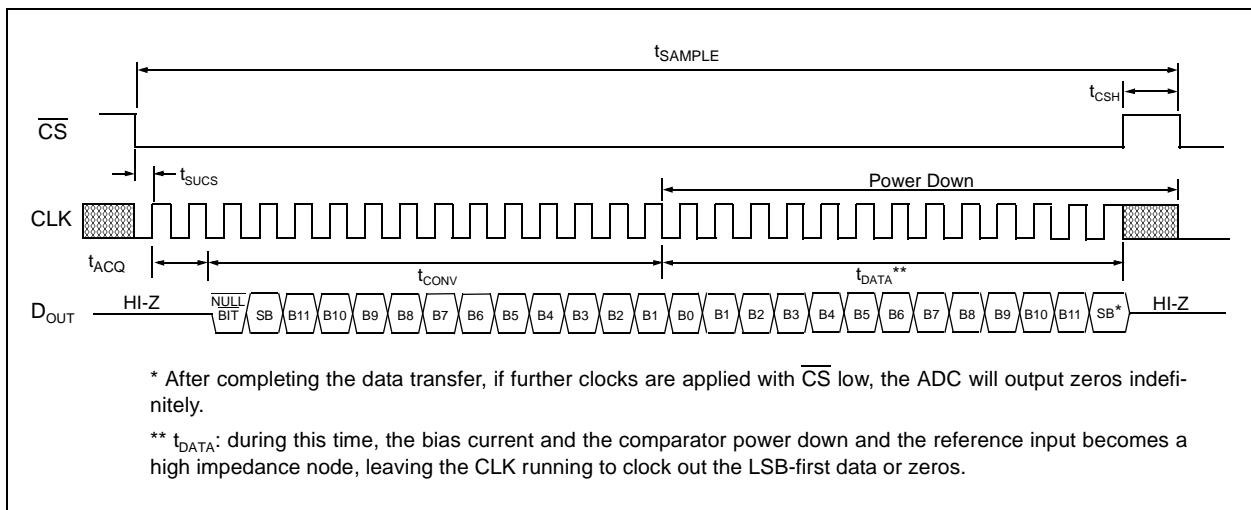

## 7.2 Communicating with the MCP3301

Communication with the device is completed using a standard SPI compatible serial interface. Initiating communication with the MCP3301 begins with the  $\overline{CS}$  going low. If the device was powered up with the  $\overline{CS}$  pin low, it must be brought high and back low to initiate communication. The device will begin to sample the analog input on the first rising edge of CLK after  $\overline{CS}$  goes low. The sample period will end in the falling edge of the second clock, at which time the device will output a low null bit. The next 13 clocks will output the result of the conversion with the sign bit first, followed by the

12 remaining data bits, as shown in Figure 7-2. Data is always output from the device on the falling edge of the clock. If all 13 data bits have been transmitted and the device continues to receive clocks while the  $\overline{CS}$  is held low, the device will output the conversion result LSB first, as shown in Figure 7-3. If more clocks are provided to the device while  $\overline{CS}$  is still low (after the LSB first data has been transmitted), the device will clock out zeros indefinitely.

**FIGURE 7-2:** Communication with MCP3301 (MSB first Format).

**FIGURE 7-3:** Communication with MCP3301 (LSB first Format).

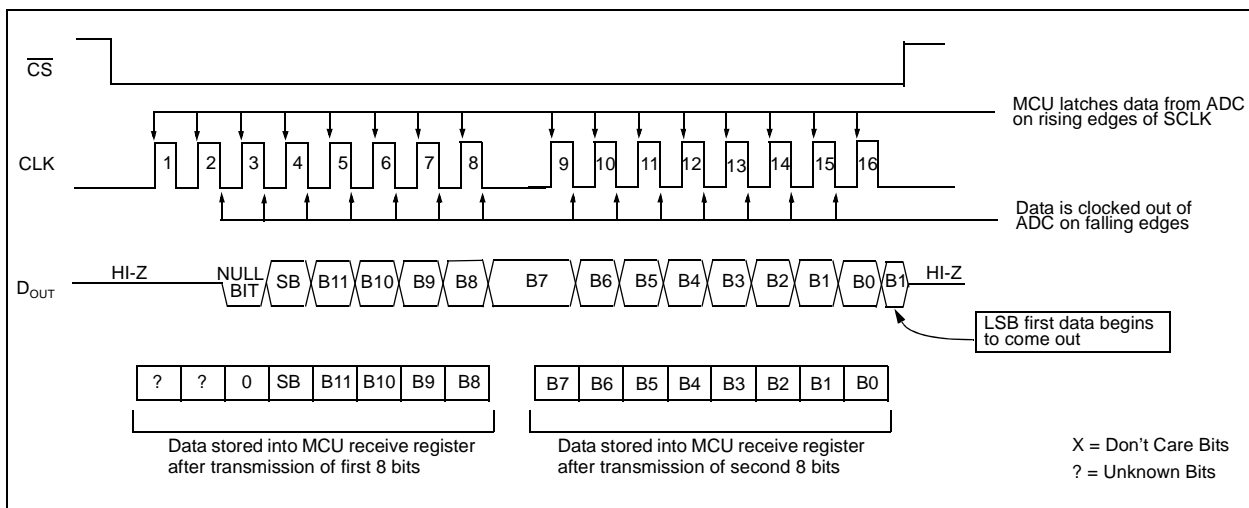

# MCP3301

## 7.3 Using the MCP3301 with Microcontroller (MCU) SPI Ports

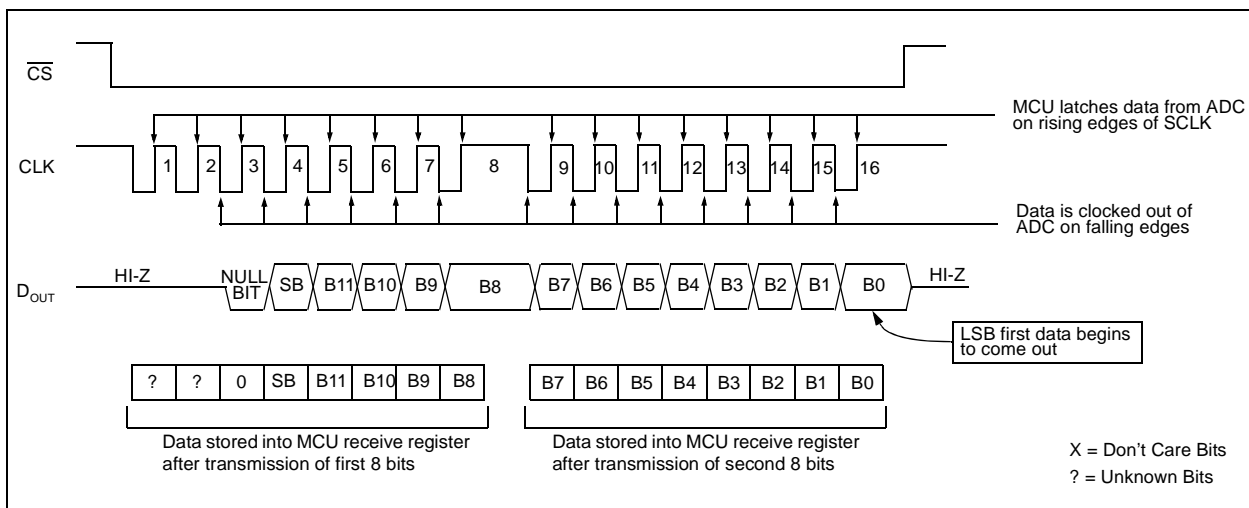

With most microcontroller SPI ports, it is required to clock out eight bits at a time. Using a hardware SPI port with the MCP3301 is very easy because each conversion requires 16 clocks. For example, Figure 7-4 and Figure 7-5 show how the MCP3301 can be interfaced to a microcontroller with a standard SPI port. Since the MCP3301 always clocks data out on the falling edge of clock, the MCU SPI port must be configured to match this operation. SPI Mode 0,0 (clock idles low) and SPI Mode 1,1 (clock idles high) are both compatible with the MCP3301. Figure 7-4 depicts the operation shown in SPI Mode 0,0, which requires that the CLK from the microcontroller idles in the 'low' state. As shown in the diagram, the sign bit is clocked out of the ADC on the

falling edge of the third clock pulse, followed by the remaining 12 data bits (MSB first). Once the first eight clocks have been sent to the device, the microcontroller's receive buffer will contain two unknown bits (for the first two clocks, the output is high impedance), followed by the null bit, the sign bit and the highest order four bits of the conversion. After the second eight clocks have been sent to the device, the MCU receive register will contain the lowest order 8 data bits. Notice that, on the falling edge of clock 16, the ADC has begun to shift out LSB first data.

Figure 7-5 shows the same scenario in SPI Mode 1,1, which requires that the clock idles in the high state. As with mode 0,0, the ADC outputs data on the falling edge of the clock and the MCU latches data from the ADC in on the rising edge of the clock.

**FIGURE 7-4:** SPI Communication with the MCP3301 using 8-bit segments (Mode 0,0: SCLK idles low).

**FIGURE 7-5:** SPI Communication with the MCP3301 using 8-bit segments (Mode 1,1: SCLK idles high).

## 8.0 PACKAGING INFORMATION

### 8.1 Package Marking Information

8-Lead MSOP

Example:

8-Lead PDIP (300 mil)

Example:

8-Lead SOIC (150 mil)

Example:

<b>Legend:</b>	XX...X	Customer-specific information
	Y	Year code (last digit of calendar year)
	YY	Year code (last 2 digits of calendar year)
	WW	Week code (week of January 1 is week '01')
	NNN	Alphanumeric traceability code
	(e3)	Pb-free JEDEC designator for Matte Tin (Sn)
	*	This package is Pb-free. The Pb-free JEDEC designator (e3) can be found on the outer packaging for this package.

**Note:** In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.

# MCP3301

## 8-Lead Plastic Micro Small Outline Package (MS) [MSOP]

**Note:** For the most current package drawings, please see the Microchip Packaging Specification located at <http://www.microchip.com/packaging>

Dimension Limits	Units	MILLIMETERS		
		MIN	NOM	MAX
Number of Pins	N	8		
Pitch	e	0.65 BSC		
Overall Height	A	–	–	1.10
Molded Package Thickness	A2	0.75	0.85	0.95
Standoff	A1	0.00	–	0.15
Overall Width	E	4.90 BSC		
Molded Package Width	E1	3.00 BSC		
Overall Length	D	3.00 BSC		
Foot Length	L	0.40	0.60	0.80
Footprint	L1	0.95 REF		
Foot Angle	$\phi$	0°	–	8°
Lead Thickness	c	0.08	–	0.23
Lead Width	b	0.22	–	0.40

**Notes:**

- Pin 1 visual index feature may vary, but must be located within the hatched area.
- Dimensions D and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.15 mm per side.
- Dimensioning and tolerancing per ASME Y14.5M.

BSC: Basic Dimension. Theoretically exact value shown without tolerances.

REF: Reference Dimension, usually without tolerance, for information purposes only.

## APPENDIX A: REVISION HISTORY

### Revision C (January 2007)

This revision includes updates to the packaging diagrams.

# MCP3301

---

NOTES:

## PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

<u>PART NO.</u>	X	X	XX
Device	Grade	Temperature Range	Package
Device:			
Grade:			
Temperature Range:			
Package:			

Device: MCP3301: 13-Bit Serial A/D Converter  
MCP3301T: 13-Bit Serial A/D Converter (Tape and Reel)

Grade: B =  $\pm 1$  LSB INL  
C =  $\pm 2$  LSB INL

Temperature Range: I = -40°C to +85°C

Package: MS = Plastic MSOP, 8-lead  
P = Plastic DIP (300 mil Body), 8-lead  
SN = Plastic SOIC (150 mil Body), 8-lead

**Examples:**

- a) MCP3301-BI/P:  $\pm 1$  LSB INL, Industrial Temperature, PDIP package
- b) MCP3301-BI/SN:  $\pm 1$  LSB INL, Industrial Temperature, SOIC package
- c) MCP3301-CI/MS:  $\pm 2$  LSB INL, Industrial Temperature, MSOP package

NOTES:

---

---

**Note the following details of the code protection feature on Microchip devices:**

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.
