

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## General Description

The MAXQ7665A-MAXQ7665D smart systems-on-a-chip (SoC) are data-acquisition systems based on a microcontroller ( $\mu$ C). As members of the MAXQ<sup>®</sup> family of 16-bit, reduced instruction set computing (RISC)  $\mu$ Cs, the MAXQ7665A-MAXQ7665D are ideal for low-cost, low-power, embedded applications such as automotive, industrial controls, and building automation. The flexible, modular architecture design used in these  $\mu$ Cs allows development of targeted products for specific applications with minimal effort.

The MAXQ7665A-MAXQ7665D incorporate a high-performance 16-bit RISC core, a 12-bit 500ksps SAR ADC with a programmable gain amplifier (PGA), and a full CAN 2.0B controller supporting transfer rates up to 1Mbps. These devices include a 12-bit DAC with a buffered voltage output and on-chip oscillator circuitry to operate from an external high frequency (8MHz) crystal. There is also a built-in internal RC oscillator as an alternative to using an external crystal. The MAXQ7665A-MAXQ7665D contain an internal temperature sensor to measure die temperature and a remote temperature-sensor driver. The analog functions and digital I/O are powered from a +5V supply, while the internal digital core is powered from +3.3V, which can be supplied by an on-chip linear regulator. These devices also include a dual power-supply supervisor with reset and a JTAG interface for in-system programming and debugging. The 16-bit RISC  $\mu$ C includes up to 128KB (64K x 16) of flash memory and 512 bytes (256 x 16) of RAM.

The MAXQ7665A-MAXQ7665D are available in a 7mm x 7mm 48-pin TQFN package and are specified to operate from -40°C to +125°C.

## Applications

Automotive Steering Sensors  
CAN- and LIN-Based Automotive Sensors  
Industrial Control

## Features

- ◆ **High-Performance, Low-Power, 16-Bit RISC Core**  
8MHz Operation, Approaching 1MIPS per MHz  
Low Power (< 3mA/MIPS, DV<sub>DD</sub> = +3.3V)  
16-Bit Instruction Word, 16-Bit Data Bus  
33 Instructions (Most Require Only One Clock Cycle)  
16-Level Hardware Stack

MAXQ is a registered trademark of Maxim Integrated Products, Inc.  
DeviceNet is a trademark of Open DeviceNet Vendor Association, Inc.

**Note:** Some revisions of this device may incorporate deviations from published specifications known as errata. Multiple revisions of any device may be simultaneously available through various sales channels. For information about device errata, go to: [www.maxim-ic.com/errata](http://www.maxim-ic.com/errata).

Three Independent Data Pointers with Automatic Increment/Decrement

- ◆ **Program and Data Memory**  
Up to 128KB (64K x 16) Internal Flash  
512 Bytes (256 x 16) Internal RAM
- ◆ **Smart Analog Peripherals**  
Low-Power, Eight Differential-Channel, 12-Bit, 500ksps ADC  
Programmable-Gain Amplifier, Software-Selectable Gain: 1V/V, 2V/V, 4V/V, 8V/V, 16V/V, 32V/V  
12-Bit DAC with Buffered Voltage Output  
External References for ADC and DAC  
Internal (Die) and External Diode Temperature Sensing
- ◆ **Timer/Digital I/O Peripherals**  
Full CAN 2.0B Controller  
15 Message Centers (256-Byte Dual Port Memory)  
Programmable Bit Rates from 10kbps to 1Mbps  
Standard 11-Bit or Extended 29-Bit Identification Modes  
Two Data Masks and Associated IDs for DeviceNET™, SDS and Other Higher Layer CAN Protocols  
External Transmit Disable for Autobaud  
SIESTA Low-Power Mode  
Wake-Up on CANRXD Edge Transition  
UART (LIN) with User-Programmable Baud Rate  
16 x 16 Hardware Multiplier with 48-Bit Accumulator, Single Clock Cycle Operation  
Three 16-Bit (or Six 8-Bit) Programmable Timer/Counter/PWM  
Eight General-Purpose, Digital I/O Pins, with External Interrupt Capability  
All Interrupts Can Be Used as a Wake-Up
- ◆ **Crystal/Clock Module**  
Internal Oscillator for Use with External Crystal  
On-Chip RC Oscillator Eliminates External Crystal  
External Clock-Source Operation  
Programmable Watchdog Timer
- ◆ **Power-Management Module**  
Power-On Reset (POR)  
Power-Supply Supervisor/Brownout Detection for Digital I/O and Digital Core Supplies  
On-Chip +3.3V, 50mA Linear Regulator
- ◆ **JTAG Interface**  
Extensive Debug and Emulation Support  
In-System Test Capability  
Flash-Memory-Program Download  
Software Bootstrap Loader for Flash Programming
- ◆ **Ultra-Low-Power Consumption**  
Low-Power, Stop Mode (CPU Shutdown)

**Ordering Information and Pin Configuration appear at end of data sheet.**

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## ABSOLUTE MAXIMUM RATINGS

DV <sub>DD</sub> to DGND, AGND, or GNDIO .....	-0.3V to +4V	Continuous Current into Any Pin.....	±50mA
DGND to GNDIO or AGND.....	-0.3V to +0.3V	Continuous Power Dissipation (T <sub>A</sub> = +70°C)	
DV <sub>DDIO</sub> to DGND, AGND, or GNDIO .....	-0.3V to +6V	48-Pin TQFN (derate 40mW/°C above +70°C) .....	3200mW
AV <sub>DD</sub> to DGND, AGND, or GNDIO.....	-0.3V to +6V	Operating Temperature Range .....	-40°C to +125°C
Digital Inputs/Outputs to DGND, AGND, or GNDIO .....	-0.3V to (DV <sub>DDIO</sub> + 0.3V)	Junction Temperature.....	+150°C
Analog Inputs/Outputs to DGND, AGND, or GNDIO .....	-0.3V to (AV <sub>DD</sub> + 0.3V)	Storage Temperature Range .....	-65°C to +150°C
RESET, XIN, XOUT to DGND, AGND, or GNDIO .....	-0.3V to (DV <sub>DD</sub> + 0.3V)	Lead Temperature (soldering, 10s) .....	+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS

(AV<sub>DD</sub> = DV<sub>DDIO</sub> = +5.0V, DV<sub>DD</sub> = +3.3V, f<sub>SYSCLOCK</sub> = 8MHz, V<sub>REFDAC</sub> = V<sub>REFADC</sub> = +5V, T<sub>A</sub> = T<sub>MIN</sub> to T<sub>MAX</sub>, unless otherwise noted. Typical values are at T<sub>A</sub> = +25°C.) (Note 1)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
<b>POWER REQUIREMENTS</b>						
Supply Voltage Range	DV <sub>DD</sub>	Safe mode (RC/2 = 3.8MHz)	2.7	3.3	3.6	V

## Pin Description

PIN	NAME	FUNCTION
1	AIN11	Analog Input Channel 11. AIN11 is multiplexed to the PGA as a differential input with AIN10.
2	AIN10	Analog Input Channel 10. AIN10 is multiplexed to the PGA as a differential input with AIN11.
3	AIN9	Analog Input Channel 9. AIN9 is multiplexed to the PGA as a differential input with AIN8.
4	AIN8	Analog Input Channel 8. AIN8 is multiplexed to the PGA as a differential input with AIN9.
5, 8	AGND	Analog Ground
6	REFADC	ADC External Reference Input. Connect an external reference voltage between 1V and AV <sub>DD</sub> to REFADC.
7	REFDAC	DAC External Reference Input. Connect an external reference voltage between 0V and AV <sub>DD</sub> to REFDAC.
9	AIN7	Analog Input Channel 7. AIN7 is multiplexed to the PGA as a differential input with AIN6.
10	AIN6	Analog Input Channel 6. AIN6 is multiplexed to the PGA as a differential input with AIN7.
11	AIN5	Analog Input Channel 5. AIN5 is multiplexed to the PGA as a differential input with AIN4.
12	AIN4	Analog Input Channel 4. AIN4 is multiplexed to the PGA as a differential input with AIN5.
13	AIN3	Analog Input Channel 3. AIN3 is multiplexed to the PGA as a differential input with AIN2. AIN3–AIN0 have remote temperature sensor capability.
14	AIN2	Analog Input Channel 2. AIN2 is multiplexed to the PGA as a differential input with AIN3. AIN3–AIN0 have remote temperature sensor capability.
15	AIN1	Analog Input Channel 1. AIN1 is multiplexed to the PGA as a differential input with AIN0. AIN3–AIN0 have remote temperature sensor capability.
16	AIN0	Analog Input Channel 0. AIN0 is multiplexed to the PGA as a differential input with AIN1. AIN3–AIN0 have remote temperature sensor capability.
17	DACOUT	DAC Buffer Output. DACOUT is the DAC voltage buffer output.
18, 19, 31	DGND	Digital Ground for the Digital Core and Flash
20	CANRXD	CAN Bus Receiver Input. Control area network receiver input.
21	CANTXD	CAN Bus Transmitter Output. Control area network transmitter output.
22	UTX	UART Transmitter Output
23	URX	UART Receiver Input
24	P0.6/T0	Port 0 Bit 6/Timer 0. P0.6 is a general-purpose digital I/O with interrupt/wake-up input capability. T0 is a primary timer/PWM input or output.
25	P0.7/T1	Port 0 Bit 7/Timer 1. P0.7 is a general-purpose digital I/O with interrupt/wake-up input capability. T1 is a primary timer/PWM input or output.
26, 39	DV <sub>DDIO</sub>	Digital I/O Supply Voltage. Supplies all digital I/O except for XIN, XOUT, and $\overline{\text{RESET}}$ . Bypass DV <sub>DDIO</sub> to GNDIO with a 0.1 $\mu$ F capacitor placed as close as possible to the device. DV <sub>DDIO</sub> is also connected to the input of the linear regulator.
27	GNDIO	Digital I/O Ground
28, 29	I.C.	Internal Connection. Connect I.C. to GNDIO or DV <sub>DDIO</sub> .
30	N.C.	No Connection. No internal connection. Leave N.C. unconnected.
32	P0.0/TDO	Port 0 Data 0/JTAG Serial Test Data Output. P0.0 is a general-purpose digital I/O with interrupt/wake-up capability. TDO is the JTAG serial test, data output.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## Pin Description (continued)

PIN	NAME	FUNCTION
33	P0.1/TMS	Port 0 Data 1/JTAG Test Mode Select. P0.1 is a general-purpose digital I/O with interrupt/wake-up capability. TMS is the JTAG test mode, select input.
34	P0.2/TDI	Port 0 Data 2/JTAG Serial Test Data Input. P0.2 is a general-purpose digital I/O with interrupt/wake-up capability. TDI is the JTAG serial test, data input.
35	P0.3/TCK	Port 0 Data 3/JTAG Serial Test Clock Input. P0.3 is a general-purpose digital I/O with interrupt/wake-up capability. TCK is the JTAG serial test, clock input.
36	P0.4/ADCCNV	Port 0 Data 4/ADC Start Conversion Control. P0.4 is a general-purpose digital I/O. ADCCNV is firmware configurable for a rising or falling edge start/convert to trigger ADC conversions.
37	P0.5/DACLOAD	Port 0 Data 5/DAC Data Register Load/Update Input. P0.5 is a general-purpose digital I/O with interrupt/wake-up capability. DACLOAD is firmware configurable for a rising or falling edge to update the DACOUT register.
38	$\overline{\text{REGEN}}$	Active-Low Linear Regulator Enable Input. Connect $\overline{\text{REGEN}}$ to GNDIO to enable the linear regulator. Connect to DVDDIO to disable the linear regulator.
40	DVDD	Digital Supply Voltage. DVDD supplies the internal digital core and flash memory. DVDD is internally connected to the output of the internal 3.3V linear regulator. Disable the internal regulator to connect DVDD to an external supply. When using the on-chip linear regulator, bypass DVDD to DGND with a 4.7 $\mu\text{F}$ $\pm 20\%$ capacitor with a maximum ESR of 0.5 $\Omega$ . In addition, bypass DVDD with a 0.1 $\mu\text{F}$ capacitor. Place both bypass capacitors as close as possible to the device.
41	$\overline{\text{RESET}}$	Reset Input and Output. Active-low open-drain input/output with internal 360k $\Omega$ pullup to DVDD. Drive low to reset the $\mu\text{C}$ . $\overline{\text{RESET}}$ is low during power-up reset and during DVDD brownout conditions.
42	XOUT	High-Frequency Crystal Output. Connect an external crystal to XIN and XOUT for normal operation. Leave XOUT unconnected if XIN is driven with an external clock source. XOUT is not driven when using the internal RC oscillator.
43	XIN	High-Frequency Crystal Input. Connect an external crystal or resonator to XIN and XOUT for normal operation, or drive XIN with an external clock source. XIN is not driven when using the internal RC oscillator.
44	AVDD	Analog Supply Voltage Input. Connect AVDD to a +5V supply. Bypass AVDD to AGND with a 0.1 $\mu\text{F}$ capacitor placed as close as possible to the device.
45	AIN15	Analog Input Channel 15. AIN15 is multiplexed to the PGA as a differential input with AIN14.
46	AIN14	Analog Input Channel 14. AIN14 is multiplexed to the PGA as a differential input with AIN15.
47	AIN13	Analog Input Channel 13. AIN13 is multiplexed to the PGA as a differential input with AIN12.
48	AIN12	Analog Input Channel 12. AIN12 is multiplexed to the PGA as a differential input with AIN13.
—	EP	Exposed Pad. EP is internally connected to AGND. Connect EP to AGND externally.

MAXQ7665A-MAXQ7665D

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## Detailed Description

The  $\mu$ C arithmetic core of the MAXQ7665A-MAXQ7665D is a 16-bit RISC machine with digital and analog peripheral functions. They incorporate a 16-bit RISC ALU with a Harvard memory architecture that can address up to 128KB (64K x 16) of flash and 512 bytes (256 x 16) of RAM memory. They also contain a hardware multiplier, up to eight digital I/Os, a controller area network (CAN 2.0B) bus, a JTAG interface, three timers, an on-chip RC oscillator, a precision 12-bit 500ksps ADC with an 8-channel differential MUX and PGA, a 12-bit precision DAC, an internal temperature sensor and temperature-sensor driver, a linear regulator, watchdog timer, and a dual power-supply supervisor.

The MAXQ offers a low  $< 3\text{mA}/\text{MIPS}$  ratio. The on-chip 16-bit x 16-bit hardware multiplier with accumulator, performs single-cycle computations. Refer to the *MAXQ7665/MAXQ7666 User's Guide* for more detailed information on configuring and programming the MAXQ7665A-MAXQ7665D.

## Analog Input Peripheral

The integrated 12-bit ADC employs an ultra-low-power, high-precision, SAR-based conversion method and can operate up to 500ksps (142ksps with  $\text{PGA} \geq 2$ ). The on-chip 8-channel differential MUX and PGA allow the ADC to measure eight fully differential analog inputs with software-selectable input ranges through the PGA. See Figure 1.

Figure 1. Simplified Analog Input Diagram (Eight Fully Differential Inputs)

## 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

The MAXQ7665A-MAXQ7665D ADC uses a fully differential SAR conversion technique and an on-chip T/H block to convert temperature and voltage signals into a 12-bit digital result. Differential configurations are supported using an analog input channel MUX that supports eight differential channels.

The differential analog inputs are selected from the following pairs: AIN0/AIN1, AIN2/AIN3, AIN4/AIN5, AIN6/AIN7, AIN8/AIN9, AIN10/AIN11, AIN12/AIN13, and AIN14/AIN15.

Remote temperature-sensor configuration in differential mode uses analog input channel pairs AIN2/AIN3 and AIN0/AIN1. In single-ended remote temperature-sensor configuration, only channels AIN2 and AIN0 are used. Internal temperature-sensor configuration measures local die temperature and does not use any analog input channel.

There are four ways to control the ADC conversion timing:

- 1) Software register bit control
- 2) Continuous conversion
- 3) Internal timers (T0, T1, or T2)
- 4) External input through pin ADCCNV

Refer to the *MAXQ7665/MAXQ7666 User's Guide* for more detailed information on the ADC and MUX.

### 12-Bit Digital-to-Analog Converter (DAC)

The MAXQ7665A-MAXQ7665D contain a 12-bit voltage-output DAC with its own output buffer. The data path to the DAC is double buffered and the output register can be updated using the DACLOAD digital input. Refer to the *MAXQ7665/MAXQ7666 User's Guide* for detailed programming information. The DAC also supports a square-wave-output toggle mode with precise amplitude control for applications that require pulse-amplitude modulation (PAM) and/or pulse-width modulation (PWM) signals. See Figure 2 for a simplified block diagram of the DAC.

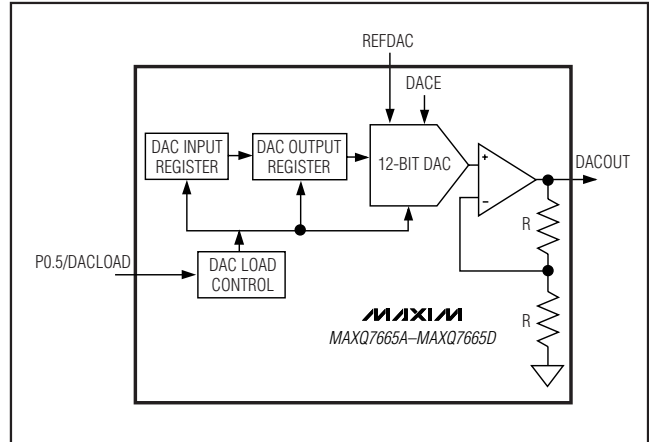

Figure 2. Simplified DAC Diagram

The DAC output buffer is in a voltage follower configuration (gain of 1V/V from REFDAC). The buffer can be disabled when not in use. When the buffer is disabled, the output is connected internally to AGND through a 100kΩ resistor. The reference input REFDAC accepts an input voltage of less than or equal to AVDD for a maximum output swing of 0V to AVDD.

### Temperature Sensor

The μC measures temperature by using the on-chip ADC and a ROM-based tempConv subroutine. Use the tempConv subroutine to initiate a measurement (refer to the *MAXQ7665/MAXQ7666 User's Guide* for detailed information). The device supports conversions of two external and one on-chip (internal) temperature sensors. The external temperature sensor is typically a diode-connected small-signal transistor, connected between two analog inputs (differential) or one analog input and AGND (single-ended). Figures 3 and 4 illustrate these two configurations.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

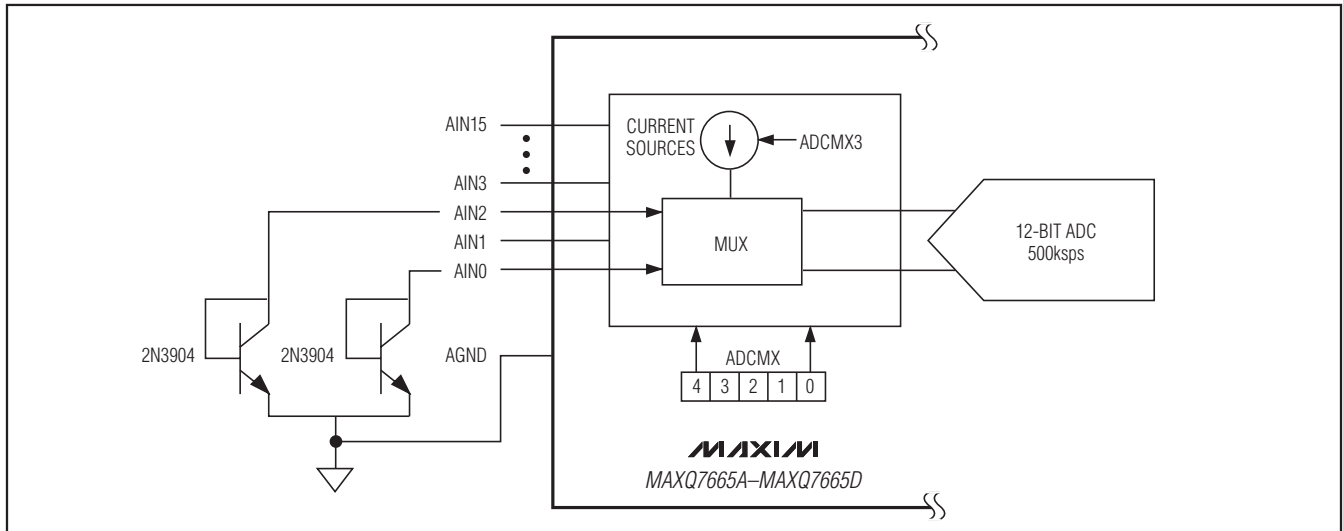

Figure 3. Temperature-Sensor Application Circuit—Single-Ended Configuration

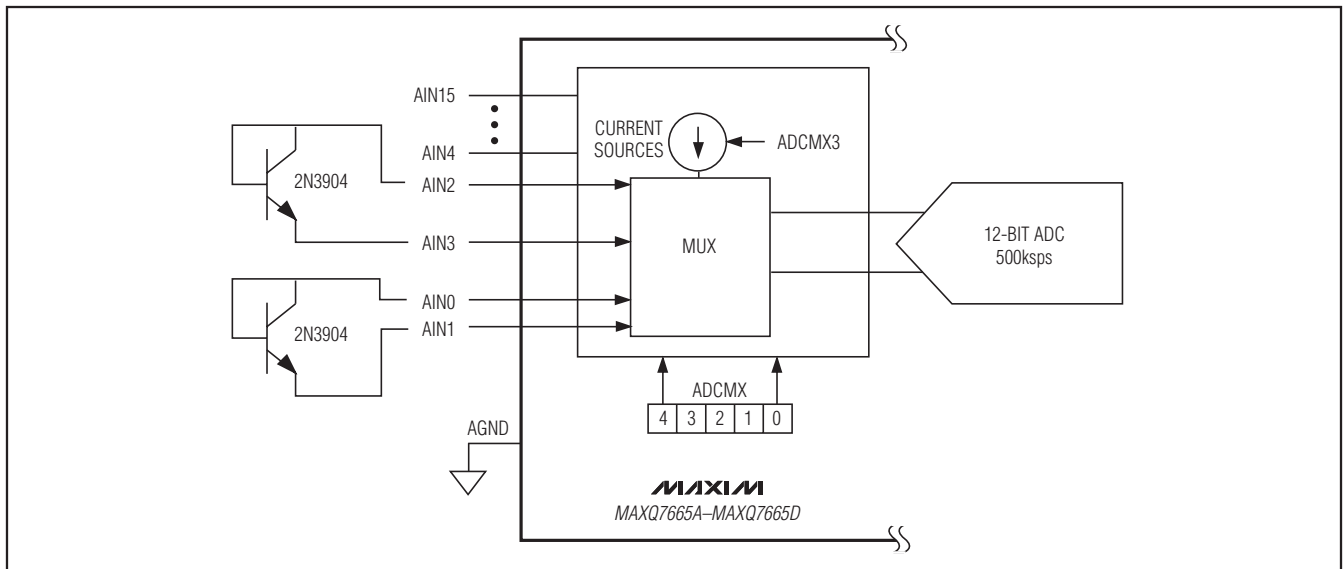

Figure 4. Temperature-Sensor Application Circuit—Differential Configuration

## Power-On Reset and Brownout

Power supplies DV<sub>DD</sub> and DV<sub>DDIO</sub> each include a brownout monitor that alerts the  $\mu$ C through interrupt when their corresponding supply voltages drop below a selectable threshold. This condition is generally referred to as brownout interrupt (BOI), and these thresholds are set by the VDBI and VIOBI bits for DV<sub>DD</sub> and DV<sub>DDIO</sub>, respectively. Continuous monitoring ensures that a valid supply is present at all times while the  $\mu$ C is executing code. For example, the brownout

monitors check that DV<sub>DDIO</sub> does not drop during a CAN bus transfer, or DV<sub>DD</sub> is not disrupted while the  $\mu$ C core is executing. The DV<sub>DDIO</sub> brownout monitor also covers the analog peripherals if AV<sub>DD</sub> and DV<sub>DDIO</sub> are directly connected.

The DV<sub>DD</sub> supply (internal core logic) also includes a voltage supervisor that controls the  $\mu$ C reset during power-up (DV<sub>DD</sub> rising) and brownout (DV<sub>DD</sub> falling) conditions (see Figure 5 for a POR and brownout timing example).

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

Figure 5. DVDD Brownout Interrupt Detection

During power-up,  $\overline{\text{RESET}}$  is held low once DVDD rises above +1.0V. All internal register bits are set to their default, POR state after DVDD exceeds a threshold of approximately +1.2V. This includes the VDBR bits which reset to 00b, resulting in a default, DVDD brownout reset (BOR) threshold in the +2.7V to +2.99V range following POR. Once DVDD rises above this DVDD brownout threshold, the 7.6MHz RC oscillator starts driving the power-up counter, and 8.6ms (typ) later, the RESET pin is released and allowed to go high if nothing external is holding it low. An important system-design consideration at power-up is the DVDD ramp-up rate should be at least 35mV/ms between +2.7V and +3.0V. This ensures  $\overline{\text{RESET}}$  is not released before DVDD reaches a minimum flash operating level of +3.0V. After DVDD has reached a valid level and  $\overline{\text{RESET}}$  is released, the  $\mu\text{C}$  jumps to the reset vector

(8000h in the utility ROM), and the desired BOI and BOR threshold values can be set by the user through the VIOBI, VDBI, and VDBR bits.

If a valid DVDD drops below its BOI threshold (set by the VDBI bits), an interrupt is generated. This offers the possibility of limited software cleanup before the DVDD BOR occurs. The amount of cleanup time depends on the VDBI and VDBR brownout threshold bit settings, the size of the DVDD bypass capacitors, and the application-dependent,  $\mu\text{C}$  power management and software cleanup tasks. Note that if the internal, +3.3V linear regulator is being used to provide DVDD, additional software cleanup time is possible by using the DVDDIO brownout monitor as an early warning that the regulator's DVDDIO (+5V) input voltage is falling, and its DVDD (+3.3V) will subsequently drop (unless DVDDIO recovers).

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

As  $DV_{DD}$  continues to fall below the  $DV_{DD}$  BOR threshold set by the  $VDBR$  bits, the  $\overline{RESET}$  pin is pulled low,  $\mu C$  and peripheral activity stops, and most, but not all of the register bits are set to their default state. This includes the  $VDBR$  bits, which retain their value if  $DV_{DD}$  falls below the BOR threshold, but not below the POR threshold.

Once  $DV_{DD}$  has entered BOR, there are a few possible scenarios:

- If  $DV_{DD}$  remains below the BOR threshold, the  $\overline{RESET}$  pin remains low, and the  $\mu C$  remains in the reset state.
- If  $DV_{DD}$  stops falling before reaching the POR threshold, then begins rising above the BOR threshold, the  $\overline{RESET}$  pin is released, and the  $\mu C$  jumps to the reset vector (8000h in the utility ROM). This is similar to the  $DV_{DD}$  power-up case described in the previous scenario, except there is no power-up counter delay and some of the register bits are set to BOR values rather than POR values. See Tables 3 and 5 for the reset behavior of specific bits. In particular, the retained  $VDBR$  setting, if higher than the default value of 00b, allows a potentially more robust brownout recovery closer to or above the minimum flash operating level of +3.0V.
- If  $DV_{DD}$  falls below the 1.2V POR threshold, all register bits are reset, and any  $DV_{DD}$  recovery from that point is identical to the power-up case described above. See Tables 3 and 5 for reset behavior of specific bits.

Refer to the *MAXQ7665/MAXQ7666 User's Guide* for detailed programming information, and a more thorough description of POR and brownout behavior.

## Internal 3.3V Linear Regulator

The MAXQ7665A–MAXQ7665D core logic supply,  $DV_{DD}$ , can be supplied by a 3.3V external supply or the on-chip 3.3V, 50mA linear regulator. To use the on-chip linear regulator, ensure the  $DV_{DDIO}$  supply can support a load of approximately 50mA and connect digital input  $\overline{REGEN}$  to  $GNDIO$ . If using an external supply, connect the regulated 3.3V supply to  $DV_{DD}$  and connect digital input  $\overline{REGEN}$  to  $DV_{DDIO}$ . If the linear regulator is not used, bring up  $DV_{DDIO}$  before  $DV_{DD}$ .

## System Clock Generator

The MAXQ7665A–MAXQ7665D oscillator module is the master clock generator that supplies the system clock for the  $\mu C$  core and all of the peripheral modules. The high-frequency (HF) oscillator is designed to operate with an 8MHz crystal. Alternatively, the on-chip RC oscillator can be used in applications that do not require precise timing. Due to its RISC design, the

MAXQ7665A–MAXQ7665D execute most instructions in a single  $SYSCLK$  period. The oscillator module contains all of the primary clock-generation circuitry. Figure 6 shows a block diagram of the system clock module.

The MAXQ7665A–MAXQ7665D contain many features for generating a master clock signal timing source:

- Internal, fast-starting, 7.6MHz RC oscillator eliminates external crystal
- Internal high-frequency oscillator that can drive an external 8MHz crystal
- External high-frequency clock input (8MHz)
- Selectable internal capacitors for HF crystal oscillator
- Power-up timer
- Power-saving management modes
- Fail-safe modes

## Watchdog Timer

The watchdog timer serves as a time-base generator, an event timer, or a system supervisor. The primary function of the watchdog timer is to supervise software execution, watching for stalled or stuck software. The watchdog timer performs a controlled system restart when the  $\mu P$  fails to write to the watchdog timer register before a selectable timeout interval expires. In some designs, the watchdog timer is also used to implement a real-time operating system (RTOS) in the  $\mu C$ . When used to implement an RTOS, a watchdog timer typically has four objectives:

- 1) To detect if a system is operating normally
- 2) To detect an infinite loop in any of the tasks
- 3) To detect an arbitration deadlock involving two or more tasks
- 4) To detect if some lower priority tasks are not getting to run because of higher priority tasks

Figure 6. High-Frequency and RC Oscillator Block Diagram

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

As illustrated in Figure 7, the high-frequency internal RC oscillator (HFRCLK) drives the watchdog timer through a series of dividers. The divider output is programmable and determines the timeout interval. When enabled, the interrupt flag WDIF is set when a timeout is reached. A system reset then occurs after a time delay (based on the divider ratio).

The watchdog timer functions as the source of both the watchdog interrupt and the watchdog reset. The interrupt timeout has a default divide ratio of  $2^{12}$  of the HFR-

CCLK, with the watchdog reset set to timeout  $2^9$  clock cycles later. With the nominal RC oscillator value of 7.6MHz, an interrupt timeout occurs every 539 $\mu$ s, followed by a watchdog reset 67.4 $\mu$ s later. The watchdog timer is reset to the default divide ratio following any reset. Using the WD0 and WD1 bits in the WDCN register, other divide ratios can be selected for longer watchdog interrupt periods. If the WD[1:0] bits are changed before the watchdog interrupt timeout occurs (i.e. before the watchdog reset counter begins), the watchdog timer count is reset. All watchdog timer reset timeouts follow the programmed interrupt timeout 512 source clock cycles later. For more information on the MAXQ7665A-MAXQ7665D watchdog timer, refer to the MAXQ7665/MAXQ7666 User's Guide.

### Timer and PWM

The MAXQ7665A-MAXQ7665D include three 16-bit timer channels. Each timer is a type 2 timer implemented in the MAXQ family (see Figure 8). Two of the timers are accessible through I/Os, and one is accessible only through software. Type 2 timers are auto-reload 16-bit timers/counters offering the following functions:

- 8-bit/16-bit timer/counter
- Up/down auto-reload
- Counter function of external pulse
- Capture
- Compare

Figure 7. Watchdog Functional Diagram

Figure 8. Type 2 Timer Functional Diagram

## 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

**Note:** The MAXQ7665A–MAXQ7665D do not have secondary timer I/O pins (such as T0B and T1B) that are present in some other MAXQ products.

### 16-Bit x 16-Bit Hardware Multiplier

A hardware multiplier supports high-speed multiplications. The multiplier is capable of completing a 16-bit x 16-bit multiply in a single cycle and contains a 48-bit accumulator that requires one more cycle. The multiplier is not part of the MAXQ core function but a peripheral that performs seven different multiply operations without interfering with the normal core functions:

- Unsigned 16-bit multiplication (one cycle)
- Unsigned 16-bit multiplication and accumulation (two cycles)
- Unsigned 16-bit multiplication and subtraction (two cycles)
- Signed 16-bit multiplication (one cycle)
- Signed 16-bit multiplication and negate (one cycle)
- Signed 16-bit multiplication and accumulation (two cycles)
- Signed 16-bit multiplication and subtraction (two cycles)

Figure 9 illustrates the simplified hardware multiplier circuitry. Two 16-bit parallel-load registers and a 48-bit

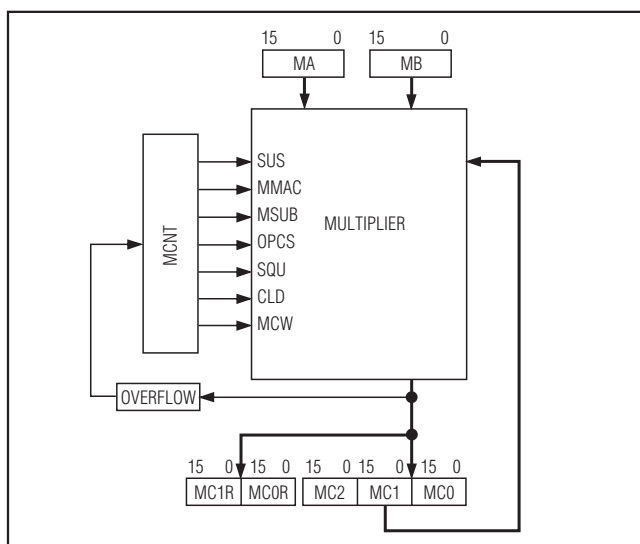

Figure 9. 16-Bit Hardware Multiplier Functional Diagram

accumulator are used: operand A (MA), operand B (MB), and accumulator (MC). The accumulator is formed by three 16-bit parallel registers (MC2, MC1, and MC0). The overflow bit is organized in the MCNT status/control register. The multiplicand and the multiplier are initially loaded into the MA and MB registers, respectively. Loading the required operands triggers the respective multiply, multiply-accumulate/subtract or multiply-negate operation. The multiply operation completes in a single cycle with the results in the read-only MC1R/MC0R register. The multiply-accumulate/subtract operation requires one extra wait cycle for the results to be stable in the MC2, MC1, and MC0 registers.

The main arithmetic unit is the 16-bit x 16-bit multiplier, which processes operands feeding from the MA and MB registers and generates a 32-bit final product. The product value goes through the 32-bit adder to perform final accumulation with zeroes for multiply operation or with the contents from the MC1 and MC0 registers for multiply-accumulation. The final sum is accessible directly from the accumulator.

To support negate operations including signed multiply-negate and signed and unsigned multiply-subtract, the operand in MA is negated by 1's complement operation before being supplied to the arithmetic unit and the partial product terms are sign corrected. Refer to the *MAXQ7665/MAXQ7666 User's Guide* for more detailed information.

### CAN Interface Bus

The MAXQ7665A–MAXQ7665D incorporate a CAN controller that is fully compliant with the CAN 2.0B specification.

The  $\mu$ C interface to the CAN controller is broken into two groups of registers. To simplify the software associated with the operation of the CAN controllers, most of the global CAN status and controls as well as the individual message center control/status registers are located in the peripheral register map. The remaining registers associated with the data identification, identification masks, format, and data are located in a dual port memory to allow the CAN controller and the processor access to the required functions. The CAN controller can directly access the dual port memory. A dedicated interface is incorporated to support dual port memory accessing by the processor through the CAN 0 data pointer (C0DP) and the CAN 0 data buffer (C0DB) special function registers.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## CAN Functional Description

The basic functions covered by the CAN controller include the use of 11-bit standard or 29-bit extended acceptance identifiers, as programmed by the  $\mu$ C for each message center, as shown in Figure 10. The CAN unit provides storage for up to 15 messages, with the standard 8-byte data field, in each message.

Each of the first 14 message centers is programmable in either transmit or receive mode. Message center 15 is designed as a receive-only message center with a buffer FIFO arrangement to help prevent the inadver-

tent loss of data when the  $\mu$ C is busy and is not allowed time to retrieve the incoming message prior to the acceptance of a second message into message center 15. Message center 15 also utilizes an independent set of mask registers and identification registers, which are only applied once an incoming message has not been accepted by any of the first 14 message centers. A second filter test is also supported for all message centers (1–15) to allow the CAN controller to use two separate 8-bit media masks and media arbitration fields to verify the contents of the first 2 bytes of data of

Figure 10. CAN 0 Controller Block Diagram

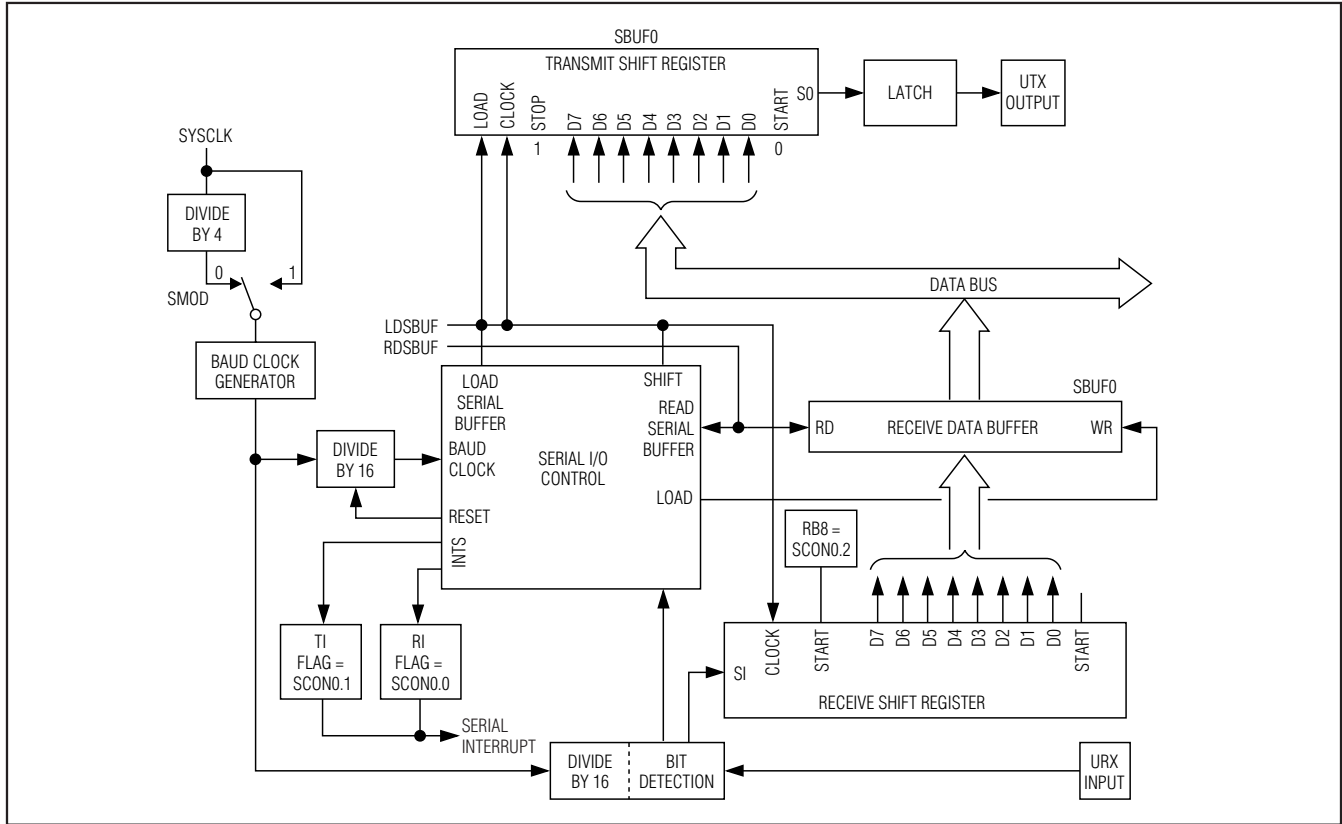

Figure 11b. UART Asynchronous Mode (Mode 1)

detection. Table 1 summarizes the operating characteristics as well as the maximum baud rate of each mode.

### JTAG Interface Bus

The joint test action group (JTAG) IEEE 1149.1 standard defines a unique method for in-circuit testing and programming. The MAXQ7665A-MAXQ7665D conform to this standard, implementing an external test access port (TAP) and internal TAP controller for communication with a JTAG bus master, such as an automatic test equipment (ATE) system. For detailed information on

the TAP and TAP controller, refer to *IEEE Standard 1149.1* on the IEEE website at <http://standards.ieee.org>. The JTAG on the MAXQ7665A-MAXQ7665D is used for in-circuit emulation and debug support, but does not support boundary scan test capability.

The TAP controller communicates synchronously with the host system (bus master) through four digital I/O pins: test mode select (TMS), test clock (TCK), test data input (TDI), and test data output (TDO). The internal TAP module consists of several shift registers and a

Table 1. Operating Characteristics and Mode Baud Rate

MODE	TYPE	BAUD CLOCK	START BITS	DATA BITS	STOP BITS	MAX BAUD RATE AT 8MHz
Mode 0	Synchronous	4 or 12 clock	N/A	8	N/A	2Mbps
Mode 1	Asynchronous	Baud generation	1	8	1	250kbps
Mode 2	Asynchronous	32 or 64 clock	1	8 + 1	1	250kbps
Mode 3	Asynchronous	Baud generation	1	8 + 1	1	250kbps

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

TAP controller (see Figure 12). The shift registers serve as transmit-and-receive data buffers for a debugger. From a JTAG perspective, shift registers are user-defined optional data registers. The bypass register and the instruction register, for example, are realized as a set of shift-register-based elements connected in parallel between a common serial input (TDI) and a common serial output (TDO). The instruction register, through the TAP controller, selects one of the registers to form an active serial path.

The maximum TCK clock frequency must be below 1/8 of the system clock frequency to work properly. The TAP operates asynchronously with on-chip system logic and may be affected by the timing relation-

ship between the on-chip state machines and the TAP. The on-chip state machines are clocked by the system clock.

The four digital I/Os that form the TAP module are described as follows:

- TDO—Serial output signal for test instruction and data. Data is driven out only on the falling edge of TCK and is forced in an inactive state when it is idle. This signal is used to serially transfer internal data to the host. Data is transferred LSB first.
- TDI—Serial input signal for test instruction and data. Data should be driven in only on the rising edge of TCK. This signal is used to serially transfer data from

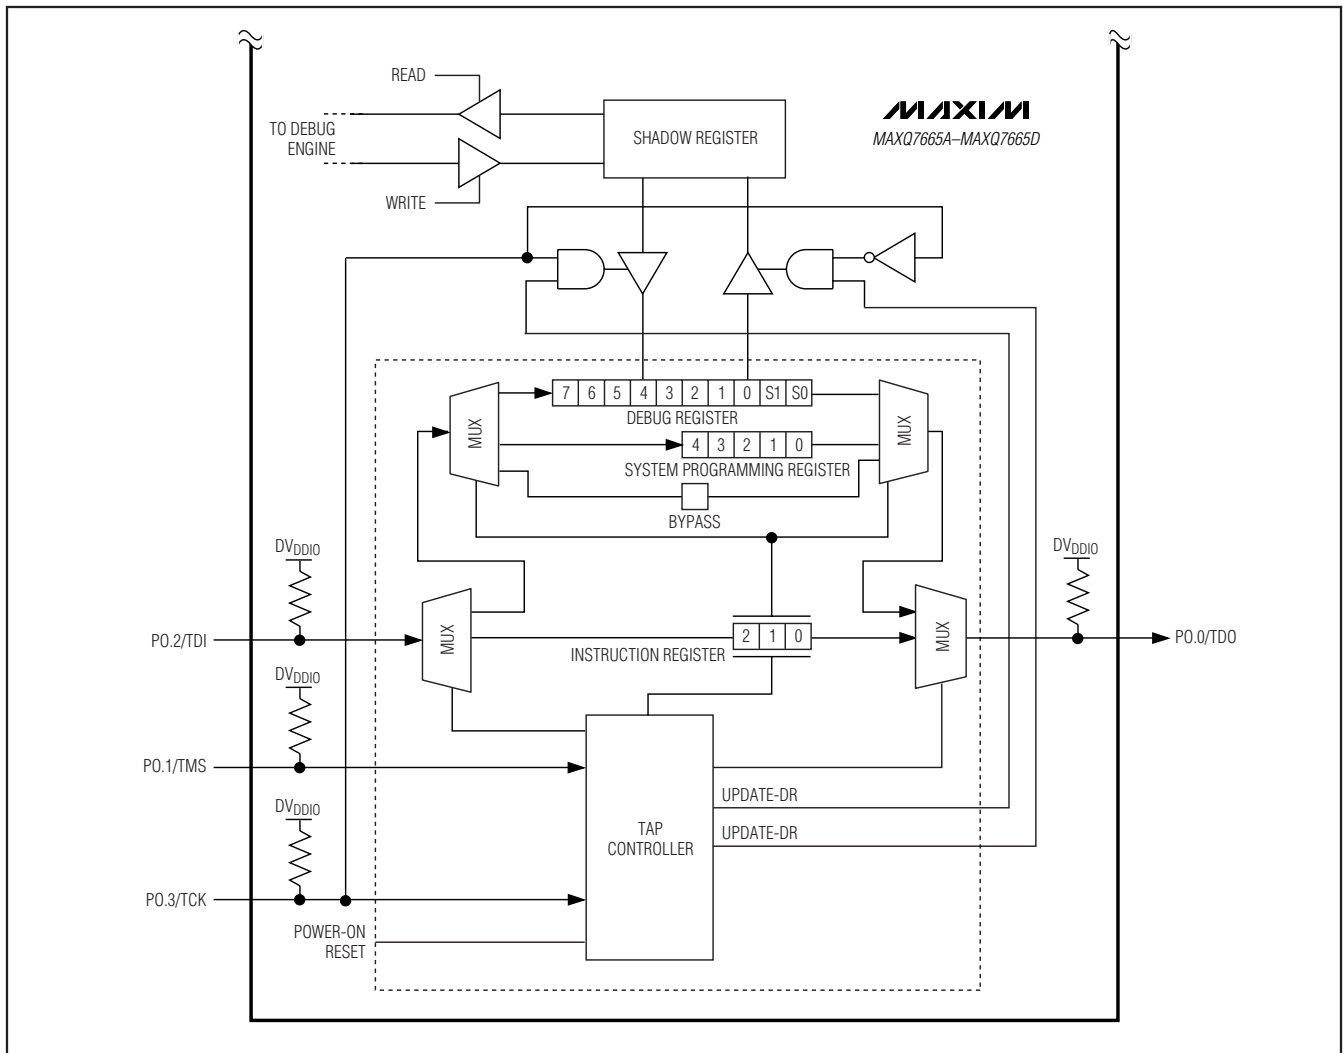

Figure 12. JTAG Interface Block Diagram

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

the host to the internal TAP module shift registers. Data is transferred LSB first.

- TCK—Serial clock for the test logic.
- TMS—Test mode selection. Test signals received at TMS are sampled at the rising edge of TCK and decoded by the TAP controller to control the test operation.

### General-Purpose Digital I/Os

The MAXQ7665A-MAXQ7665D provide eight general-purpose digital I/Os (GPIOs). All GPIOs have an additional special function (SF), such as a timer input/output, or TAP signal for JTAG communication. For example, the state of pin P0.6/T0 can be programmed to depend on timer channel 0 logic. When programmed as a port, each I/O is configurable for high-impedance or weak pullup to DVDDIO. At power-up, each GPIO is configured as an input with pullups to DVDDIO. Note that at power-up, the JTAG function is enabled and should be turned off before normal operation. In addition, each GPIO can be programmed to cause an interrupt (on falling or rising edges). In stop mode, any interrupt can be used to wake up the device.

The data input/output direction in a port is independently controlled by the port direction register (PD). Each I/O within the port can be individually set as an output or input. The port output register (PO) contains the current state of the logic output buffers. When an

I/O is configured as an output, writing to the PO register controls the output logic state. Reading the PO register shows the current state of the output buffers, independent of the data direction. The port input register (PI) is a read-only register that always reflects the logic state of the I/Os. When an I/O is configured as an input, writing to the PO register enables/disables the pull-up resistor. Refer to the *MAXQ7665/MAXQ7666 User's Guide* for more detailed information.

### Port Characteristics

The MAXQ7665A-MAXQ7665D contain only one port (P0). It is a bidirectional 8-bit I/O port, which contains the following features:

- Schmitt trigger input circuitry with software-selectable high-impedance or weak pullup to DVDDIO
- Software-selectable push-pull CMOS output drivers capable of sinking and sourcing 1.6mA
- Software-selectable open-drain output drivers capable of sinking 1.6mA
- Falling or rising edge interrupt capability
- All I/Os contain an additional special function, such as a logic input/output for a timer channel. Selecting an I/O for a special function alters the port characteristics of that I/O (refer to the *MAXQ7665/MAXQ7666 User's Guide* for more details). Figure 13 illustrates the functional blocks of an I/O.

Figure 13. Digital I/O Circuitry

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## MAXQ Core Architecture

The MAXQ7665A–MAXQ7665D are low-cost, high-performance, CMOS, fully static, 16-bit  $\mu$ Cs with flash memory and are members of the MAXQ family of  $\mu$ Cs. The MAXQ7665A–MAXQ7665D are structured on a highly advanced, accumulator-based, 16-bit RISC architecture. Fetch and execution operations are completed in one cycle without pipelining, because the instruction contains both the operation code and data. The result is a streamlined 8 million instructions-per-second (MIPS)  $\mu$ C.

The highly efficient core is supported by a 16-level hardware stack, enabling fast subroutine calling and task switching. Data can be quickly and efficiently manipulated with three internal data pointers. Multiple data pointers allow more than one function to access data memory without having to save and restore data pointers each time. The data pointers can automatically increment or decrement following an operation, eliminating the need for software intervention. As a result, application speed is greatly increased.

## Instruction Set

The instruction set is composed of fixed-length, 16-bit instructions that operate on registers and memory locations. The instruction set is highly orthogonal, allowing arithmetic and logical operations to use any register along with the accumulator. Special-function registers (also called peripheral registers) control the peripherals and are subdivided into register modules. The family architecture is modular, so that new devices and modules can reuse code developed for existing products.

The architecture is transport-triggered. This means that writes or reads from certain register locations can also cause side effects to occur. These side effects form the basis for the higher level operation codes defined by the assembler, such as ADDC, OR, JUMP, etc. The operation codes are actually implemented as MOVE instructions between certain register locations, while the assembler handles the encoding, which need not be a concern to the programmer.

The 16-bit instruction word is designed for efficient execution. Bit 15 indicates the format for the source field of the instruction. Bits 0 to 7 of the instruction represent the

source for the transfer. Depending on the value of the format field, this can either be an immediate value or a source register. If this field represents a register, the lower 4 bits contain the module specifier and the upper 4 bits contain the register index in that module.

Bits 8 to 14 represent the destination for the transfer. This value always represents a destination register, with the lower 4 bits containing the module specifier and the upper 3 bits containing the register subindex within that module. Any time that it is necessary to directly select one of the upper 24 registers as a destination, the prefix register, PFX, is needed to supply the extra destination bits. This prefix register write is inserted automatically by the assembler and requires only one additional execution cycle.

## Memory Organization

The MAXQ7665A–MAXQ7665D incorporate several memory areas:

- 8KB (4K x 16) utility ROM
- Up to 128KB (64K x 16) of flash memory for program storage
- 512 bytes (256 x 16) of SRAM for storage of temporary variables
- 16-level stack memory for storage of program return addresses and general-purpose use

The memory is arranged by default in a Harvard architecture, with separate address spaces for program and data memory (see Figure 14). A special mode allows data memory to be mapped into program space, permitting code execution from data memory. In addition, another mode allows program memory to be mapped into data space, permitting code constants to be accessed as data memory.

The incorporation of flash memory allows the devices to be reprogrammed, eliminating the expense of throwing away one-time programmable devices during development and field upgrades (see Figure 15 for the flash memory sector maps). Flash memory can be password protected with a 16-word key, denying access to program memory by unauthorized individuals.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

Figure 14. MAXQ7665B Memory Map

A pseudo-Von Neumann memory map can also be enabled. This places the utility ROM, code, and data memory into a single contiguous memory map. This is useful for applications that require dynamic program modification or unique memory configurations.

### Stack Memory

A 16-bit-wide x 16 deep internal hardware stack provides storage for program return addresses and general-purpose use. The stack is used automatically by the processor when the CALL, RET, and RETI instructions are executed and interrupts serviced. The stack can also be used explicitly to store and retrieve data by using the PUSH, POP, and POPI instructions.

On reset, the stack pointer, SP, initializes to the top of the stack (0Fh). The CALL, PUSH, and interrupt-vectoring

operations increment SP, then store a value at the location pointed to by SP. The RET, RETI, POP, and POPI operations retrieve the value at SP and then decrement SP.

### Utility ROM

The utility ROM is an 8KB (4K x 16) block of internal ROM memory that defaults to a starting address of 8000h. The utility ROM consists of subroutines that can be called from application software. These include:

- In-system programming (bootstrap loader) over JTAG
- In-circuit debug routines
- User-callable routines for in-application flash programming and fast table lookup

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

Following any reset, execution begins in the utility ROM. The ROM software determines whether the program execution should immediately jump to location 0000h, the start of user-application code, or to one of the special routines mentioned. Routines within the utility ROM are user-accessible and can be called as sub-routines by the application software. More information on the utility ROM contents is contained in the *MAXQ7665/MAXQ7666 User's Guide*.

Some applications require protection against unauthorized viewing of program code memory. For these applications, access to in-system programming, in-application programming, or in-circuit debugging functions is prohibited until a password has been supplied. The password is defined as the 16 words of physical program memory at addresses 0010h to 001Fh.

A single password lock (PWL) bit is implemented in the SC register. When the PWL is set to one (POR default), the password is required to access the utility ROM, including in-circuit debug and in-system programming routines that allow reading or writing of internal memory. When PWL is cleared to zero, these utilities are fully accessible without the password. The password is automatically set to all ones following a mass erase.

## Programming

The flash memory of the  $\mu\text{C}$  can be programmed by two different methods: in-system programming and in-application programming. Both methods afford great flexibility in system design as well as reduce the life-cycle cost of the embedded system. These features can be password protected to prevent unauthorized access to program memory.

### In-System Programming

An internal bootstrap loader allows the device to be reloaded over a simple JTAG interface. As a result, software can be upgraded in-system, eliminating the need for a costly hardware retrofit when updates are required. Remote software uploads are possible that enable physically inaccessible applications to be frequently updated. The interface hardware can be a JTAG connection to another  $\mu\text{C}$ , or a connection to a PC serial port using a serial-to-JTAG converter such as the MAXQJTAG-001, available from Maxim Integrated Products, Inc. If in-system programmability is not required, a commercial gang programmer can be used for mass programming.

After a power-up or reset, the JTAG interface is active and loading the TAP with the system programming instruction invokes the bootstrap loader. Setting the SPE bit to 1 during reset through the JTAG interface executes the bootstrap-loader-mode program that resides in the utility ROM. When programming is complete, the bootstrap loader can clear the SPE bit and reset the device, allowing the device to bypass the utility ROM and begin execution of the application software.

The following bootstrap loader functions are supported:

- Load
- Dump
- CRC
- Verify
- Erase

### In-Application Programming

The in-application programming feature allows the  $\mu\text{C}$  to modify its own flash program memory while simultaneously executing its application software. This allows on-the-fly software updates in mission-critical applications that cannot afford downtime. Alternatively, it allows the application to develop custom loader software that can operate under the control of the application software. The utility ROM contains user-accessible flash programming functions that erase and program flash memory. These functions are described in detail in the *MAXQ7665/MAXQ7666 User's Guide* for these devices.

## Register Set

Most functions of these devices are controlled by sets of registers. These registers provide a working space for memory operations as well as configuring and addressing peripheral registers on the device. Registers are divided into two major types: system registers and peripheral registers. The common register set, also known as the system registers, includes the ALU, accumulator registers, data pointers, interrupt vectors and control, and stack pointer. The peripheral registers define additional functionality that may be included by different products based on the MAXQ architecture. This functionality is broken up into discrete modules so that only the features required for a given product need to be included. Tables 2 and 4 show the MAXQ7665A–MAXQ7665D register set. Tables 3 and 5 show the bit functions and reset values.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

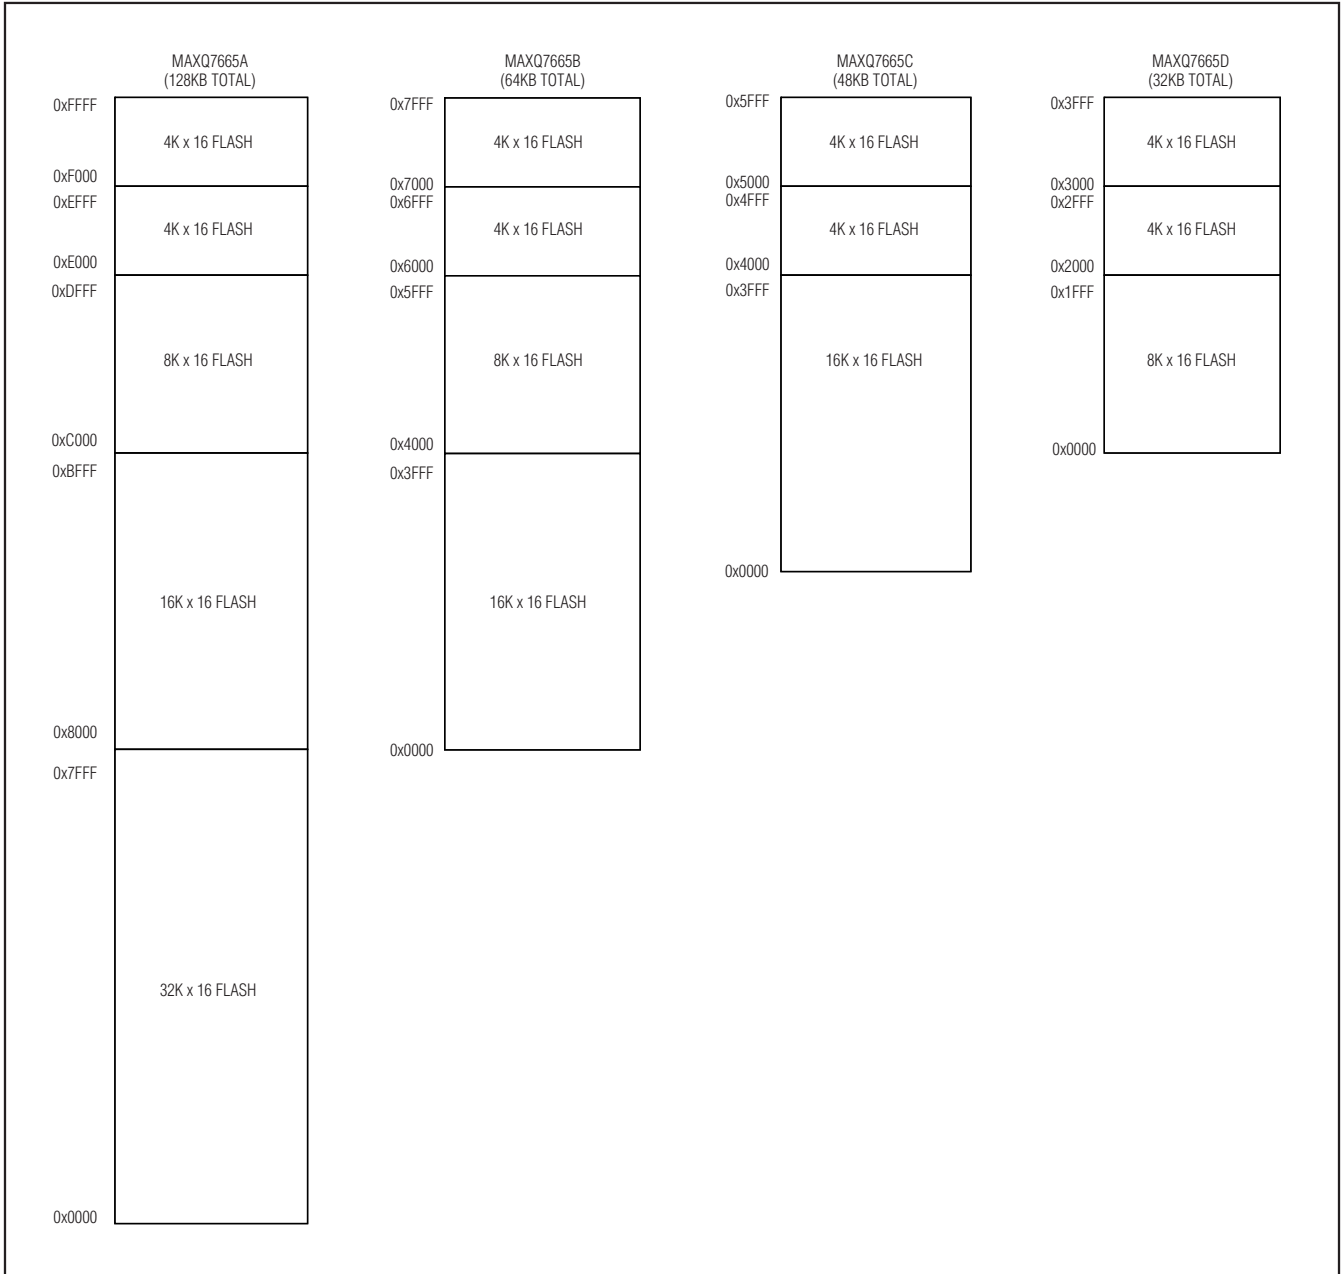

Figure 15. Flash Memory Sector Maps

## Power Management

Power consumption reaches its minimum in stop mode. In this mode, the external oscillator, internal RC oscillator, system clock, and all processing activity is halted. Stop mode is exited when an enabled external interrupt input is triggered or an external reset signal is applied

to  $\overline{\text{RESET}}$ . Upon exiting stop mode, the  $\mu\text{C}$  can choose to wait for the external high-frequency crystal to complete its warmup period, or it can start execution immediately from its internal RC oscillator while the warmup period completes.

**Note:** Names that appear in italics indicate that all bits of a register are read-only. Names that appear in bold indicate that a register is 16 bits wide.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## Interrupts

Multiple interrupt sources are available for quick response to internal and external events. The MAXQ architecture uses a single interrupt vector (IV), single interrupt-service routine (ISR) design. For maximum flexibility, interrupts can be enabled globally, individually, or by module. When an interrupt condition occurs, its individual flag is set, even if the interrupt source is disabled at the local, module, or global level. Interrupt flags must be cleared within the user-interrupt routine to avoid repeated false interrupts from the same source. Application software must ensure a delay between the write to the flag and the RETI instruction to allow time for the interrupt hardware to remove the internal interrupt condition. Asynchronous interrupt flags require a one-instruction delay and synchronous interrupt flags require a two-instruction delay.

When an enabled interrupt is detected, software jumps to a user-programmable interrupt vector location. The IV register defaults to 0000h on reset or power-up, so if it is not changed to a different address, the user program must determine whether a jump to 0000h came from a reset or interrupt source.

Once software control has been transferred to the ISR, the interrupt identification register (IIR) can be used to determine if a system register or peripheral register was the source of the interrupt. The specified module can then be interrogated for the specific interrupt source and software can take appropriate action. Because the interrupts are evaluated by user software, the user can define a unique interrupt priority scheme for each application. The following interrupt sources are available.

- Watchdog interrupt
- External interrupts 0 to 7
- Serial port 0 receive and transmit interrupts

- Timer 0 low compare, low overflow, capture/compare, and overflow interrupts
- Timer 1 low compare, low overflow, capture/compare, and overflow interrupts
- Timer 2 low compare, low overflow, and overflow interrupts
- CAN0 receive and transmit interrupts and a change in CAN0 status register interrupt
- ADC data ready and overrun interrupts
- Digital and I/O voltage brownout interrupts
- High-frequency oscillator failure interrupt

## Reset Sources

Several reset sources are provided for  $\mu$ C control. Although code execution is halted in the reset state, the high-frequency oscillator and the internal RC oscillator continue to oscillate. The high-frequency oscillator is turned off by a POR, but not by other reset sources. Internal resets such as the power-on and watchdog resets assert the  $\overline{\text{RESET}}$  output low.

### Power-On Reset (POR)

An internal POR circuit enhances system reliability. This circuit forces the device to perform a POR whenever a rising voltage on  $\text{DV}_{\text{DD}}$  climbs above the POR threshold level of 2.7V. At this point the following events occur:

- All registers and circuits enter their reset state
- The POR flag (WDCN.POR) is set to indicate the source of the reset
- The internal RC oscillator becomes the clock source
- Code execution begins at location 8000h

### Watchdog Timer Reset

The watchdog timer functions are described in the *MAXQ7665/MAXQ7666 User's Guide*. Execution resumes at location 8000h following a watchdog timer reset.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## External System Reset

Asserting the external  $\overline{\text{RESET}}$  input low causes the device to enter the reset state. The external reset functions as described in the *MAXQ7665/MAXQ7666 User's Guide*. Execution resumes at location 8000h after  $\overline{\text{RESET}}$  is released.

## Crystal Selection

The MAXQ7665A–MAXQ7665D require a crystal with the following specifications:

Frequency: 8MHz

$C_{\text{LOAD}}$ : 6pF (min)

Drive level: 5 $\mu$ W

Series resonance resistance: 30 $\Omega$  max

**Note:** Series resonance resistance is the resistance observed when the resonator is in the series resonant condition. This is a parameter often stated by quartz crystal vendors and is called R1. When a resonator is used in the parallel resonant mode with an external load capacitance, as is the case with the MAXQ7665A–MAXQ7665D oscillator circuit, the effective resistance is sometimes stated. This effective resistance at the loaded frequency of oscillation is:

$$R1 \times (1 + (C_0/C_{\text{LOAD}}))^2$$

For typical  $C_0$  and  $C_{\text{LOAD}}$  values, the effective resistance can be greater than R1 by a factor of 2.

## Development and Technical Support

A variety of highly versatile, affordably priced development tools for this  $\mu$ C are available from Maxim and third-party suppliers, including:

- Compilers
- Evaluation kits
- Integrated development environments (IDEs)
- JTAG-to-serial converters for programming and debugging

A list of some development-tool vendors can be found at [www.maxim-ic.com/microcontrollers](http://www.maxim-ic.com/microcontrollers).

Technical support is available through email at [maxq.support@maxim-ic.com](mailto:maxq.support@maxim-ic.com).

OSCC (M5, Ch)	0	0	0	0	0	—	—	—	—	—	—	—	—	—	—	—	—

Bits indicated by "—" are unused.

Bits indicated by "ST" reflect the input signal state.

Bits indicated by "S" are only affected by a POR and not by other forms of reset. These bits are set to 0 after a POR.

Bits indicated by "DB" have read/write access only in background or debug mode. These bits are cleared after a POR.

Bits indicated by "DW" are only written to in debug mode. These bits are cleared after a POR.

The OSCC register is cleared to 0002h after a POR and is not affected by other forms of reset.

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

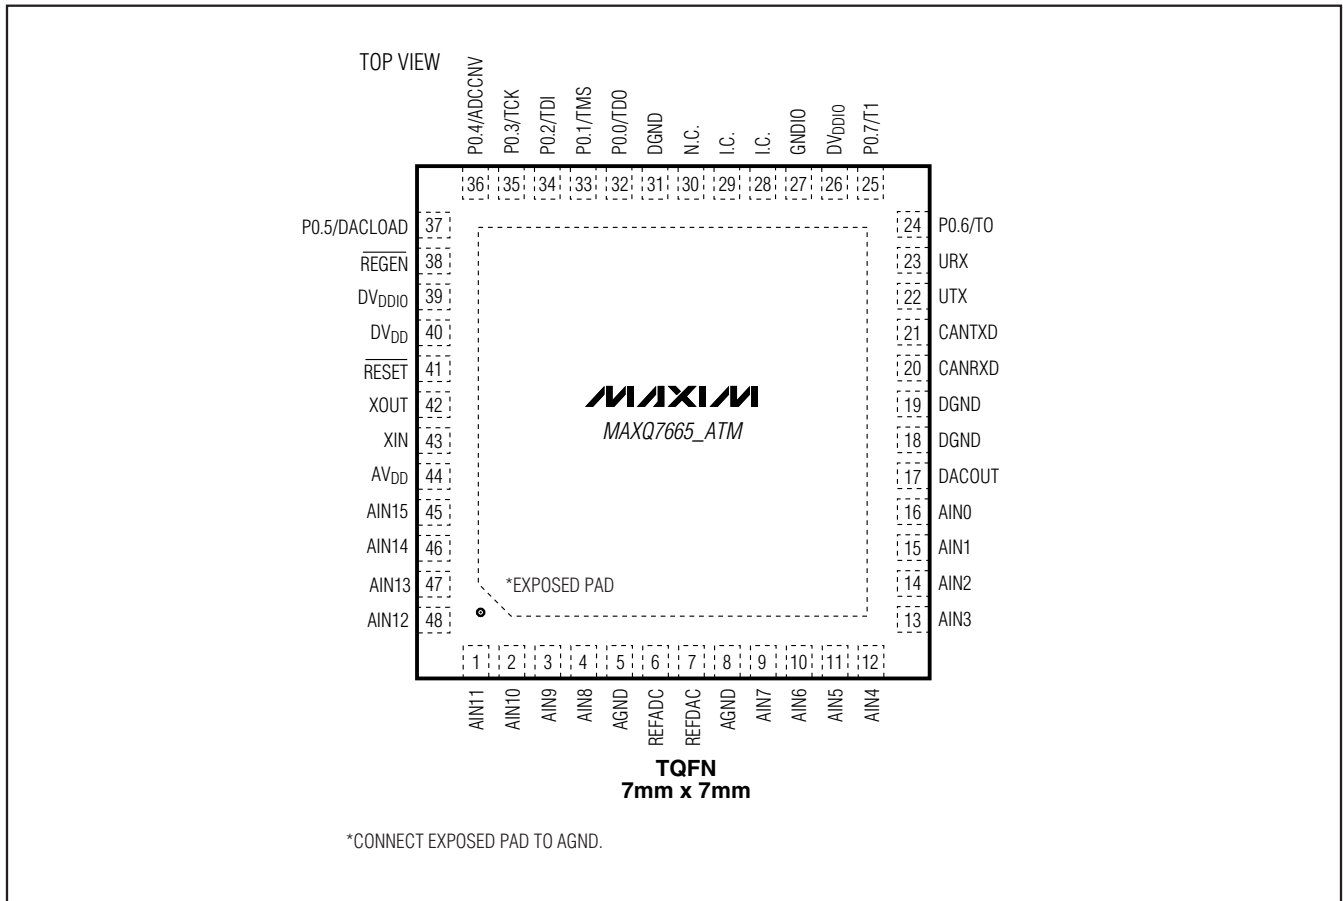

## Typical Operating Circuit

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## Pin Configuration

MAXQ7665A-MAXQ7665D

## Chip Information

PROCESS: BiCMOS and CMOS

# 16-Bit RISC Microcontroller-Based Smart Data-Acquisition Systems

## Ordering Information

PART	PIN-PACKAGE	FLASH SIZE (KB)
MAXQ7665AATM+**	48 TQFN-EP*	128 (64K x 16)
MAXQ7665BATM+	48 TQFN-EP*	64 (32K x 16)
MAXQ7665CATM+**	48 TQFN-EP*	48 (24K x 16)
MAXQ7665DATM+**	48 TQFN-EP*	32 (16K x 16)

+Devices are only available in lead(Pb)-free packaging.

\*EP = Exposed pad.

\*\*Future Product—contact factory for availability.

**Note:** All devices are specified for operation over the -40°C to +125°C automotive temperature range.

## Package Information

For the latest package outline information and land patterns, go to [www.maxim-ic.com/packages](http://www.maxim-ic.com/packages).
