# 36-Mbit (1M x 36/2M x 18/512K x 72) Pipelined SRAM with NoBL™ Architecture

## Features

- Pin-compatible and functionally equivalent to ZBT™
- Supports 250-MHz bus operations with zero wait states
  - Available speed grades are 250, 200 and 167 MHz
- Internally self-timed output buffer control to eliminate the need to use asynchronous  $\overline{OE}$
- Fully registered (inputs and outputs) for pipelined operation
- Byte Write capability
- Single 2.5V power supply
- 2.5V/1.8V I/O operation
- Fast clock-to-output times
  - 2.6 ns (for 250-MHz device)
  - 3.2 ns (for 200-MHz device)
  - 3.4 ns (for 167-MHz device)
- Clock Enable (CEN) pin to suspend operation
- Synchronous self-timed writes
- CY7C1460AV25 and CY7C1462AV25 available in lead-free 100 TQFP and 165 fBGA packages  
CY7C1464AV25 available in 209-Ball fBGA package
- IEEE 1149.1 JTAG Boundary Scan
- Burst capability—linear or interleaved burst order
- “ZZ” Sleep Mode option and Stop Clock option

## Functional Description

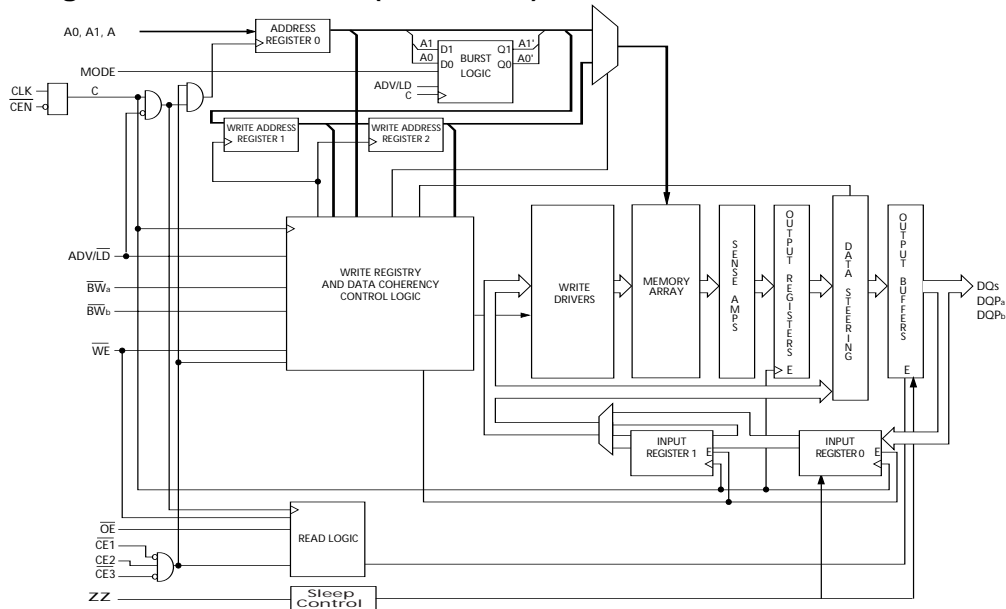

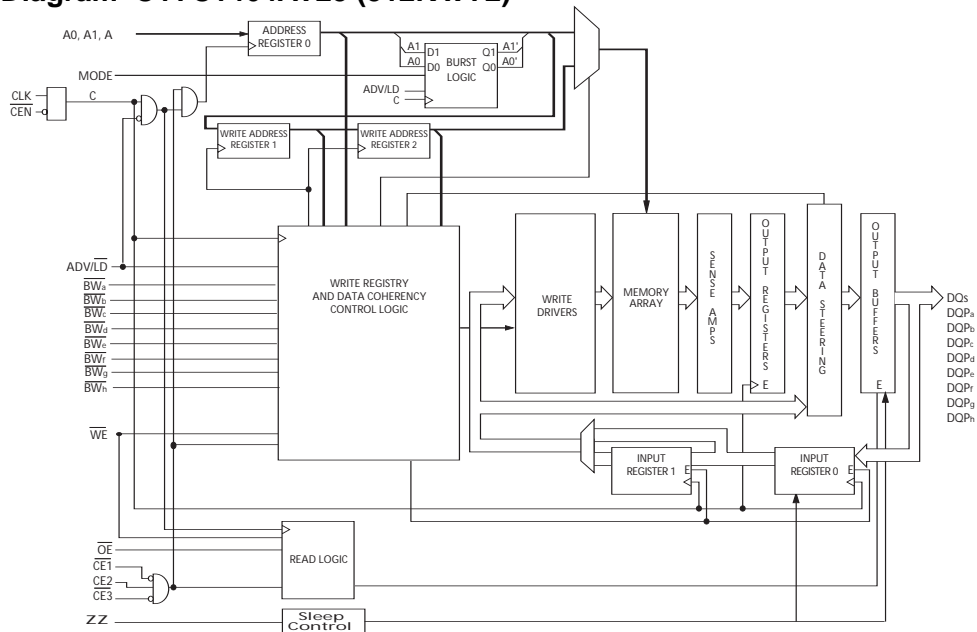

The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 are 2.5V, 1-Mbit x 36/2-Mbit x 18/Synchronous pipelined burst SRAMs with No Bus Latency™ (NoBL™) logic, respectively. They are designed to support unlimited true back-to-back Read/Write operations with no wait states. The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 are equipped with the advanced (NoBL) logic required to enable consecutive Read/Write operations with data being transferred on every clock cycle. This feature dramatically improves the throughput of data in systems that require frequent Write/Read transitions. The CY7C1460AV25/ CY7C1462AV25/ CY7C1464AV25 are pin-compatible and functionally equivalent to ZBT devices.

All synchronous inputs pass through input registers controlled by the rising edge of the clock. All data outputs pass through output registers controlled by the rising edge of the clock. The clock input is qualified by the Clock Enable (CEN) signal, which when deasserted suspends operation and extends the previous clock cycle. Write operations are controlled by the Byte Write Selects ( $\overline{BW}_a$ – $\overline{BW}_h$  for CY7C1464AV25,  $\overline{BW}_a$ – $\overline{BW}_d$  for CY7C1460AV25 and  $\overline{BW}_a$ – $\overline{BW}_b$  for CY7C1462AV25) and a Write Enable (WE) input. All writes are conducted with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Enables ( $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$ ) and an asynchronous Output Enable ( $\overline{OE}$ ) provide for easy bank selection and output three-state control. In order to avoid bus contention, the output drivers are synchronously three-stated during the data portion of a write sequence.

**Pin Definitions**

Pin Name	I/O Type	Pin Description
A0 A1 A	Input-Synchronous	<b>Address Inputs used to select one of the address locations.</b> Sampled at the rising edge of the CLK.
$\overline{BW}_a$ $\overline{BW}_b$ $\overline{BW}_c$ $\overline{BW}_d$ $\overline{BW}_e$ $\overline{BW}_f$ $\overline{BW}_g$ $\overline{BW}_h$	Input-Synchronous	<b>Byte Write Select Inputs, active LOW.</b> Qualified with WE to conduct writes to the SRAM. Sampled on the rising edge of CLK. $\overline{BW}_a$ controls DQ <sub>a</sub> and DQP <sub>a</sub> , $\overline{BW}_b$ controls DQ <sub>b</sub> and DQP <sub>b</sub> , $\overline{BW}_c$ controls DQ <sub>c</sub> and DQP <sub>c</sub> , $\overline{BW}_d$ controls DQ <sub>d</sub> and DQP <sub>d</sub> , $\overline{BW}_e$ controls DQ <sub>e</sub> and DQP <sub>e</sub> , $\overline{BW}_f$ controls DQ <sub>f</sub> and DQP <sub>f</sub> , $\overline{BW}_g$ controls DQ <sub>g</sub> and DQP <sub>g</sub> , $\overline{BW}_h$ controls DQ <sub>h</sub> and DQP <sub>h</sub> .
WE	Input-Synchronous	<b>Write Enable Input, active LOW.</b> Sampled on the rising edge of CLK if CEN is active LOW. This signal must be asserted LOW to initiate a write sequence.
A0 A1 A	Input-Synchronous	<b>Address Inputs used to select one of the address locations.</b> Sampled at the rising edge of the CLK.

**Pin Definitions** (continued)

Pin Name	I/O Type	Pin Description
BW <sub>a</sub> BW <sub>b</sub> BW <sub>c</sub> BW <sub>d</sub> BW <sub>e</sub> BW <sub>f</sub> BW <sub>g</sub> BW <sub>h</sub>	Input-Synchronous	<b>Byte Write Select Inputs, active LOW.</b> Qualified with WE to conduct writes to the SRAM. Sampled on the rising edge of CLK. BW <sub>a</sub> controls DQ <sub>a</sub> and DQP <sub>a</sub> , BW <sub>b</sub> controls DQ <sub>b</sub> and DQP <sub>b</sub> , BW <sub>c</sub> controls DQ <sub>c</sub> and DQP <sub>c</sub> , BW <sub>d</sub> controls DQ <sub>d</sub> and DQP <sub>d</sub> , BW <sub>e</sub> controls DQ <sub>e</sub> and DQP <sub>e</sub> , BW <sub>f</sub> controls DQ <sub>f</sub> and DQP <sub>f</sub> , BW <sub>g</sub> controls DQ <sub>g</sub> and DQP <sub>g</sub> , BW <sub>h</sub> controls DQ <sub>h</sub> and DQP <sub>h</sub> .
WE	Input-Synchronous	<b>Write Enable Input, active LOW.</b> Sampled on the rising edge of CLK if CEN is active LOW. This signal must be asserted LOW to initiate a write sequence.
ADV/LD	Input-Synchronous	<b>Advance/Load Input used to advance the on-chip address counter or load a new address.</b> When HIGH (and CEN is asserted LOW) the internal burst counter is advanced. When LOW, a new address can be loaded into the device for an access. After being deselected, ADV/LD should be driven LOW in order to load a new address.
ADV/LD	Input-Synchronous	<b>Advance/Load Input used to advance the on-chip address counter or load a new address.</b> When HIGH (and CEN is asserted LOW) the internal burst counter is advanced. When LOW, a new address can be loaded into the device for an access. After being deselected, ADV/LD should be driven LOW in order to load a new address.
CLK	Input-Clock	<b>Clock Input.</b> Used to capture all synchronous inputs to the device. CLK is qualified with CEN. CLK is only recognized if CEN is active LOW.
CE <sub>1</sub>	Input-Synchronous	<b>Chip Enable 1 Input, active LOW.</b> Sampled on the rising edge of CLK. Used in conjunction with CE <sub>2</sub> and CE <sub>3</sub> to select/deselect the device.
CE <sub>2</sub>	Input-Synchronous	<b>Chip Enable 2 Input, active HIGH.</b> Sampled on the rising edge of CLK. Used in conjunction with CE <sub>1</sub> and CE <sub>3</sub> to select/deselect the device.
CE <sub>3</sub>	Input-Synchronous	<b>Chip Enable 3 Input, active LOW.</b> Sampled on the rising edge of CLK. Used in conjunction with CE <sub>1</sub> and CE <sub>2</sub> to select/deselect the device.
OE	Input-Asynchronous	<b>Output Enable, active LOW.</b> Combined with the synchronous logic block inside the device to control the direction of the I/O pins. When LOW, the I/O pins are allowed to behave as outputs. When deasserted HIGH, I/O pins are tri-stated, and act as input data pins. OE is masked during the data portion of a write sequence, during the first clock when emerging from a deselected state and when the device has been deselected.
CEN	Input-Synchronous	<b>Clock Enable Input, active LOW.</b> When asserted LOW the clock signal is recognized by the SRAM. When deasserted HIGH the clock signal is masked. Since deasserting CEN does not deselect the device, CEN can be used to extend the previous cycle when required.
DQ <sub>a</sub> DQ <sub>b</sub> DQ <sub>c</sub> DQ <sub>d</sub> DQ <sub>e</sub> DQ <sub>f</sub> DQ <sub>g</sub> DQ <sub>h</sub>	I/O-Synchronous	<b>Bidirectional Data I/O lines.</b> As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by A <sub>x</sub> during the previous clock rise of the read cycle. The direction of the pins is controlled by OE and the internal control logic. When OE is asserted LOW, the pins can behave as outputs. When HIGH, DQ <sub>a</sub> –DQ <sub>d</sub> are placed in a tri-state condition. The outputs are automatically tri-stated during the data portion of a write sequence, during the first clock when emerging from a deselected state, and when the device is deselected, regardless of the state of OE.
DQP <sub>a</sub> DQP <sub>b</sub> DQP <sub>c</sub> DQP <sub>d</sub> DQP <sub>e</sub> DQP <sub>f</sub> DQP <sub>g</sub> DQP <sub>h</sub>	I/O-Synchronous	<b>Bidirectional Data Parity I/O lines.</b> Functionally, these signals are identical to DQ <sub>[31:0]</sub> . During write sequences, DQP <sub>a</sub> is controlled by BW <sub>a</sub> , DQP <sub>b</sub> is controlled by BW <sub>b</sub> , DQP <sub>c</sub> is controlled by BW <sub>c</sub> , and DQP <sub>d</sub> is controlled by BW <sub>d</sub> , DQP <sub>e</sub> is controlled by BW <sub>e</sub> , DQP <sub>f</sub> is controlled by BW <sub>f</sub> , DQP <sub>g</sub> is controlled by BW <sub>g</sub> , DQP <sub>h</sub> is controlled by BW <sub>h</sub> .
MODE	Input Strap Pin	<b>Mode Input.</b> Selects the burst order of the device. Tied HIGH selects the interleaved burst order. Pulled LOW selects the linear burst order. MODE should not change states during operation. When left floating MODE will default HIGH, to an interleaved burst order.
TDO	JTAG serial output Synchronous	<b>Serial data-out to the JTAG circuit.</b> Delivers data on the negative edge of TCK.
TDI	JTAG serial input Synchronous	<b>Serial data-In to the JTAG circuit.</b> Sampled on the rising edge of TCK.

**Pin Definitions** (continued)

Pin Name	I/O Type	Pin Description
TMS	Test Mode Select Synchronous	<b>This pin controls the Test Access Port state machine.</b> Sampled on the rising edge of TCK.
TCK	JTAG-Clock	<b>Clock input to the JTAG circuitry.</b>
V <sub>DD</sub>	Power Supply	<b>Power supply inputs to the core of the device.</b>
V <sub>DDQ</sub>	I/O Power Supply	<b>Power supply for the I/O circuitry.</b>
V <sub>SS</sub>	Ground	<b>Ground for the device.</b> Should be connected to ground of the system.
NC	N/A	<b>No connects.</b> This pin is not connected to the die.
NC/72M	N/A	<b>Not connected to the die.</b> Can be tied to any voltage level.
NC/144M	N/A	<b>Not connected to the die.</b> Can be tied to any voltage level.
NC/288M	N/A	<b>Not connected to the die.</b> Can be tied to any voltage level.
ZZ	Input-Asynchronous	<b>ZZ “sleep” Input.</b> This active HIGH input places the device in a non-time critical “sleep” condition with data integrity preserved. During normal operation, this pin can be connected to V <sub>ss</sub> or left floating.

**Introduction**
**Functional Overview**

The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 are synchronous-pipelined Burst NoBL SRAMs designed specifically to eliminate wait states during Write/Read transitions. All synchronous inputs pass through input registers controlled by the rising edge of the clock. The clock signal is qualified with the Clock Enable input signal (CEN). If CEN is HIGH, the clock signal is not recognized and all internal states are maintained. All synchronous operations are qualified with CEN. All data outputs pass through output registers controlled by the rising edge of the clock. Maximum access delay from the clock rise ( $t_{CO}$ ) is 2.6 ns (250-MHz device).

Accesses can be initiated by asserting all three Chip Enables ( $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$ ) active at the rising edge of the clock. If Clock Enable (CEN) is active LOW and ADV/LD is asserted LOW, the address presented to the device will be latched. The access can either be a read or write operation, depending on the status of the Write Enable (WE).  $BW_{[x]}$  can be used to conduct byte write operations.

Write operations are qualified by the Write Enable ( $\overline{WE}$ ). All writes are simplified with on-chip synchronous self-timed write circuitry.

Three synchronous Chip Enables ( $\overline{CE}_1$ ,  $\overline{CE}_2$ ,  $\overline{CE}_3$ ) and an asynchronous Output Enable (OE) simplify depth expansion. All operations (Reads, Writes, and Deselects) are pipelined. ADV/LD should be driven LOW once the device has been deselected in order to load a new address for the next operation.

**Single Read Accesses**

A read access is initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW, (2)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are ALL asserted active, (3) the Write Enable input signal WE is deasserted HIGH, and (4) ADV/LD is asserted LOW. The address presented to the address inputs is latched into the Address Register and presented to the memory core and control logic. The control logic determines that a read access is in progress and allows the requested data to propagate to the input of the output register. At the rising edge of the next clock the requested data is allowed to propagate through the output register and onto the data bus within 2.6 ns (200-MHz device) provided  $\overline{OE}$  is active LOW. After the first clock of the read access the output buffers are controlled by

$\overline{OE}$  and the internal control logic.  $\overline{OE}$  must be driven LOW in order for the device to drive out the requested data. During the second clock, a subsequent operation (Read/Write/Deselect) can be initiated. Deselecting the device is also pipelined. Therefore, when the SRAM is deselected at clock rise by one of the chip enable signals, its output will three-state following the next clock rise.

**Burst Read Accesses**

The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 have an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four Reads without reasserting the address inputs. ADV/LD must be driven LOW in order to load a new address into the SRAM, as described in the Single Read Access section above. The sequence of the burst counter is determined by the MODE input signal. A LOW input on MODE selects a linear burst mode, a HIGH selects an interleaved burst sequence. Both burst counters use A0 and A1 in the burst sequence, and will wrap-around when incremented sufficiently. A HIGH input on ADV/LD will increment the internal burst counter regardless of the state of chip enables inputs or WE. WE is latched at the beginning of a burst cycle. Therefore, the type of access (Read or Write) is maintained throughout the burst sequence.

**Single Write Accesses**

Write access are initiated when the following conditions are satisfied at clock rise: (1) CEN is asserted LOW, (2)  $\overline{CE}_1$ ,  $\overline{CE}_2$ , and  $\overline{CE}_3$  are ALL asserted active, and (3) the write signal WE is asserted LOW. The address presented to the address inputs is loaded into the Address Register. The write signals are latched into the Control Logic block.

On the subsequent clock rise the data lines are automatically three-stated regardless of the state of the OE input signal. This allows the external logic to present the data on DQ and DQP ( $DQ_{a,b,c,d,e,f,g,h}/DQP_{a,b,c,d,e,f,g,h}$  for CY7C1464AV25,  $DQ_{a,b,c,d}/DQP_{a,b,c,d}$  for CY7C1460AV25 and  $DQ_{a,b}/DQP_{a,b}$  for CY7C1462AV25). In addition, the address for the subsequent access (Read/Write/Deselect) is latched into the Address Register (provided the appropriate control signals are asserted).

On the next clock rise the data presented to DQ and DQP ( $DQ_{a,b,c,d,e,f,g,h}/DQP_{a,b,c,d,e,f,g,h}$  for CY7C1464AV25,  $DQ_{a,b,c,d}/DQP_{a,b,c,d}$  for CY7C1460AV25 and  $DQ_{a,b}/DQP_{a,b}$  for CY7C1462AV25) (or a subset for byte write operations, see

Write Cycle Description table for details) inputs is latched into the device and the write is complete.

The data written during the Write operation is controlled by  $\overline{BW}$  ( $BW_{a,b,c,d,e,f,g,h}$  for CY7C1464AV25,  $BW_{a,b,c,d}$  for CY7C1460AV25 and  $BW_{a,b}$  for CY7C1462AV25) signals. The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 provides byte write capability that is described in the Write Cycle Description table. Asserting the Write Enable input (WE) with the selected Byte Write Select ( $\overline{BW}$ ) input will selectively write to only the desired bytes. Bytes not selected during a byte write operation will remain unaltered. A synchronous self-timed write mechanism has been provided to simplify the write operations. Byte write capability has been included in order to greatly simplify Read/Modify/Write sequences, which can be reduced to simple byte write operations.

Because the CY7C1460AV25/CY7C1462AV25/ CY7C1464AV25 are common I/O devices, data should not be driven into the device while the outputs are active. The Output Enable (OE) can be deasserted HIGH before presenting data to the DQ and DQP ( $DQ_{a,b,c,d,e,f,g,h}/DQP_{a,b,c,d,e,f,g,h}$  for CY7C1464AV25,  $DQ_{a,b,c,d}/DQP_{a,b,c,d}$  for CY7C1460AV25 and  $DQ_{a,b}/DQP_{a,b}$  for CY7C1462AV25) inputs. Doing so will three-state the output drivers. As a safety precaution, DQ and DQP ( $DQ_{a,b,c,d,e,f,g,h}/DQP_{a,b,c,d,e,f,g,h}$  for CY7C1464AV25,  $DQ_{a,b,c,d}/DQP_{a,b,c,d}$  for CY7C1460AV25 and  $DQ_{a,b}/DQP_{a,b}$  for CY7C1462AV25) are automatically three-stated during the data portion of a write cycle, regardless of the state of OE.

#### Burst Write Accesses

The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 has an on-chip burst counter that allows the user the ability to supply a single address and conduct up to four WRITE operations without reasserting the address inputs. ADV/LD must be driven LOW in order to load the initial address, as described in the Single Write Access section above. When ADV/LD is driven HIGH on the subsequent clock rise, the chip enables ( $CE_1$ ,  $CE_2$ , and  $CE_3$ ) and WE inputs are ignored and the burst counter is incremented. The correct BW ( $BW_{a,b,c,d,e,f,g,h}$  for

CY7C1460AV25,  $\overline{BW}_{a,b,c,d}$  for CY7C1460AV25 and  $\overline{BW}_{a,b}$  for CY7C1462AV25) inputs must be driven in each cycle of the burst write in order to write the correct bytes of data.

#### Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode.  $CE_1$ ,  $CE_2$ , and  $CE_3$ , must remain inactive for the duration of  $t_{ZZREC}$  after the ZZ input returns LOW.

#### Interleaved Burst Address Table (MODE = Floating or $V_{DD}$ )

First Address	Second Address	Third Address	Fourth Address
A1,A0	A1,A0	A1,A0	A1,A0
00	01	10	11
01	00	11	10
10	11	00	01
11	10	01	00

#### Linear Burst Address Table (MODE = GND)

First Address	Second Address	Third Address	Fourth Address
A1,A0	A1,A0	A1,A0	A1,A0
00	01	10	11
01	10	11	00
10	11	00	01
11	00	01	10

#### ZZ Mode Electrical Characteristics

Parameter	Description	Test Conditions	Min.	Max	Unit
$I_{DDZZ}$	Sleep mode standby current	$ZZ \geq V_{DD} - 0.2V$		100	mA
$t_{ZZS}$	Device operation to ZZ	$ZZ \geq V_{DD} - 0.2V$		$2t_{CYC}$	ns
$t_{ZZREC}$	ZZ recovery time	$ZZ \leq 0.2V$	$2t_{CYC}$		ns
$t_{ZZI}$	ZZ active to sleep current	This parameter is sampled		$2t_{CYC}$	ns
$t_{RZZI}$	ZZ Inactive to exit sleep current	This parameter is sampled	0		ns

### IEEE 1149.1 Serial Boundary Scan (JTAG)

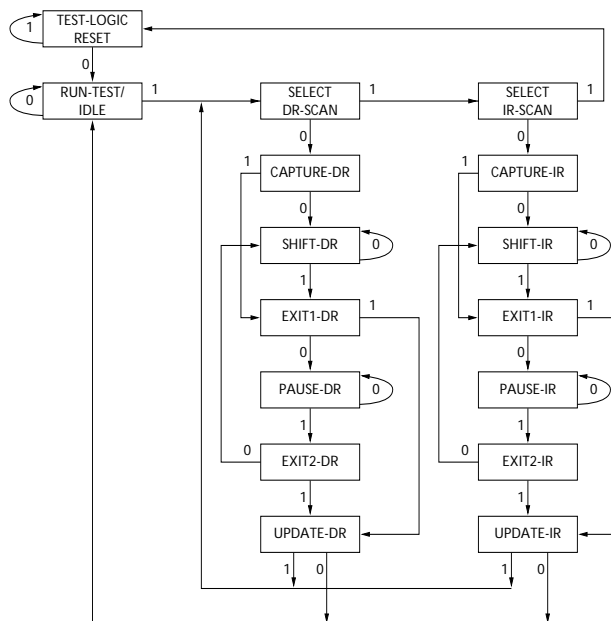

The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 incorporates a serial boundary scan test access port (TAP). This part is fully compliant with 1149.1. The TAP operates using JEDEC-standard 2.5V/1.8V I/O logic level.

The CY7C1460AV25/CY7C1462AV25/CY7C1464AV25 contains a TAP controller, instruction register, boundary scan register, bypass register, and ID register.

#### Disabling the JTAG Feature

It is possible to operate the SRAM without using the JTAG feature. To disable the TAP controller, TCK must be tied LOW(Vss) to prevent clocking of the device. TDI and TMS are internally pulled up and may be unconnected. They may alternately be connected to VDD through a pull-up resistor. TDO should be left unconnected. Upon power-up, the device will come up in a reset state which will not interfere with the operation of the device.

### TAP Controller State Diagram

The 0/1 next to each state represents the value of TMS at the rising edge of TCK.

### Test Access Port (TAP)

#### Test Clock (TCK)

The test clock is used only with the TAP controller. All inputs are captured on the rising edge of TCK. All outputs are driven from the falling edge of TCK.

#### Test MODE SELECT (TMS)

The TMS input is used to give commands to the TAP controller and is sampled on the rising edge of TCK. It is allowable to leave this ball unconnected if the TAP is not used. The ball is pulled up internally, resulting in a logic HIGH level.

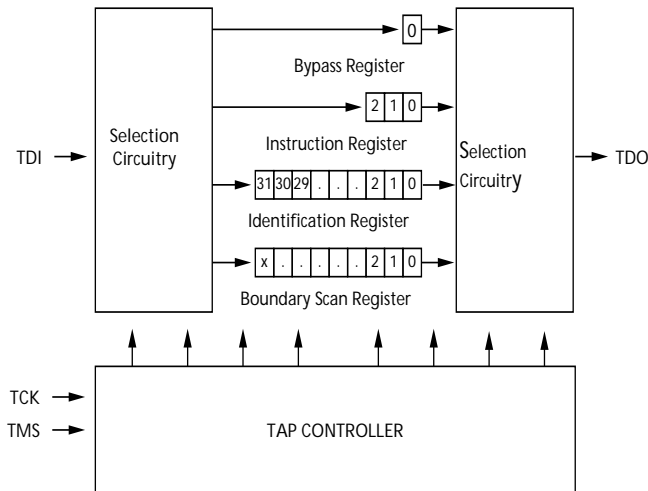

#### Test Data-In (TDI)

The TDI ball is used to serially input information into the registers. The register between TDI and TDO is chosen by the instruction that is loaded into the TAP instruction register. For information on loading the instruction register, see Figure . TDI is internally pulled up and can be unconnected if the TAP is unused in an application. TDI is connected to the most significant bit (MSB) of any register. (See Tap Controller Block Diagram.)

#### Test Data-Out (TDO)

The TDO output ball is used to serially clock data-out from the registers. The output is active depending upon the current state of the TAP state machine. The output changes on the falling edge of TCK. TDO is connected to the least significant bit (LSB) of any register. (See Tap Controller State Diagram.)

## TAP Controller Block Diagram

### Performing a TAP Reset

A RESET is performed by forcing TMS HIGH (VDD) for five rising edges of TCK. This RESET does not affect the operation of the SRAM and may be performed while the SRAM is operating.

At power-up, the TAP is reset internally to ensure that TDO comes up in a High-Z state.

### TAP Registers

Registers are connected between the TDI and TDO balls and allow data to be scanned into and out of the SRAM test circuitry. Only one register can be selected at a time through the instruction register. Data is serially loaded into the TDI ball on the rising edge of TCK. Data is output on the TDO ball on the falling edge of TCK.

### Instruction Register

Three-bit instructions can be serially loaded into the instruction register. This register is loaded when it is placed between the TDI and TDO balls as shown in the Tap Controller Block Diagram. Upon power-up, the instruction register is loaded with the IDCODE instruction. It is also loaded with the IDCODE instruction if the controller is placed in a reset state as described in the previous section.

When the TAP controller is in the Capture-IR state, the two least significant bits are loaded with a binary "01" pattern to allow for fault isolation of the board-level serial test data path.

### Bypass Register

To save time when serially shifting data through registers, it is sometimes advantageous to skip certain chips. The bypass register is a single-bit register that can be placed between the TDI and TDO balls. This allows data to be shifted through the SRAM with minimal delay. The bypass register is set LOW (Vss) when the BYPASS instruction is executed.

### Boundary Scan Register

The boundary scan register is connected to all the input and bidirectional balls on the SRAM. The length of the Boundary Scan Register for the SRAM in different packages is listed in the Scan Register Sizes table.

The boundary scan register is loaded with the contents of the RAM I/O ring when the TAP controller is in the Capture-DR state and is then placed between the TDI and TDO balls when the controller is moved to the Shift-DR state. The EXTEST, SAMPLE/PRELOAD and SAMPLE Z instructions can be used to capture the contents of the I/O ring.

The Boundary Scan Order tables show the order in which the bits are connected. Each bit corresponds to one of the bumps on the SRAM package. The MSB of the register is connected to TDI, and the LSB is connected to TDO.

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions table.

### Identification (ID) Register

The ID register is loaded with a vendor-specific, 32-bit code during the Capture-DR state when the IDCODE command is loaded in the instruction register. The IDCODE is hardwired into the SRAM and can be shifted out when the TAP controller is in the Shift-DR state. The ID register has a vendor code and other information described in the Identification Register Definitions table.

### TAP Instruction Set

#### Overview

Eight different instructions are possible with the three bit instruction register. All combinations are listed in the Instruction Codes table. Three of these instructions are listed as RESERVED and should not be used. The other five instructions are described in detail below.

Instructions are loaded into the TAP controller during the Shift-IR state when the instruction register is placed between TDI and TDO. During this state, instructions are shifted through the instruction register through the TDI and TDO balls. To execute the instruction once it is shifted in, the TAP controller needs to be moved into the Update-IR state.

#### IDCODE

The IDCODE instruction causes a vendor-specific, 32-bit code to be loaded into the instruction register. It also places the instruction register between the TDI and TDO balls and allows the IDCODE to be shifted out of the device when the TAP controller enters the Shift-DR state.

The IDCODE instruction is loaded into the instruction register upon power-up or whenever the TAP controller is given a test logic reset state.

#### SAMPLE Z

The SAMPLE Z instruction causes the boundary scan register to be connected between the TDI and TDO pins when the TAP controller is in a Shift-DR state. The SAMPLE Z command puts the output bus into a High-Z state until the next command is given during the "Update IR" state.

#### SAMPLE/PRELOAD

SAMPLE/PRELOAD is a 1149.1-mandatory instruction. When the SAMPLE/PRELOAD instructions are loaded into the instruction register and the TAP controller is in the Capture-DR state, a snapshot of data on the inputs and output pins is captured in the boundary scan register.

The user must be aware that the TAP controller clock can only operate at a frequency up to 20 MHz, while the SRAM clock operates more than an order of magnitude faster. Because there is a large difference in the clock frequencies, it is possible that during the Capture-DR state, an input or output will undergo a transition. The TAP may then try to capture a signal while in transition (metastable state). This will not harm the device, but there is no guarantee as to the value that will be captured. Repeatable results may not be possible.

To guarantee that the boundary scan register will capture the correct value of a signal, the SRAM signal must be stabilized long enough to meet the TAP controller's capture set-up plus hold times ( $t_{CS}$  and  $t_{CH}$ ). The SRAM clock input might not be captured correctly if there is no way in a design to stop (or slow) the clock during a SAMPLE/PRELOAD instruction. If this is an issue, it is still possible to capture all other signals and simply ignore the value of the CK and CK# captured in the boundary scan register.

Once the data is captured, it is possible to shift out the data by putting the TAP into the Shift-DR state. This places the boundary scan register between the TDI and TDO pins.

PRELOAD allows an initial data pattern to be placed at the latched parallel outputs of the boundary scan register cells prior to the selection of another boundary scan test operation.

The shifting of data for the SAMPLE and PRELOAD phases can occur concurrently when required - that is, while data captured is shifted out, the preloaded data can be shifted in.

### BYPASS

When the BYPASS instruction is loaded in the instruction register and the TAP is placed in a Shift-DR state, the bypass register is placed between the TDI and TDO pins. The advantage of the BYPASS instruction is that it shortens the boundary scan path when multiple devices are connected together on a board.

### EXTEST

The EXTEST instruction enables the preloaded data to be driven out through the system output pins. This instruction also

selects the boundary scan register to be connected for serial access between the TDI and TDO in the shift-DR controller state.

### EXTEST Output Bus Tri-State

IEEE Standard 1149.1 mandates that the TAP controller be able to put the output bus into a tri-state mode.

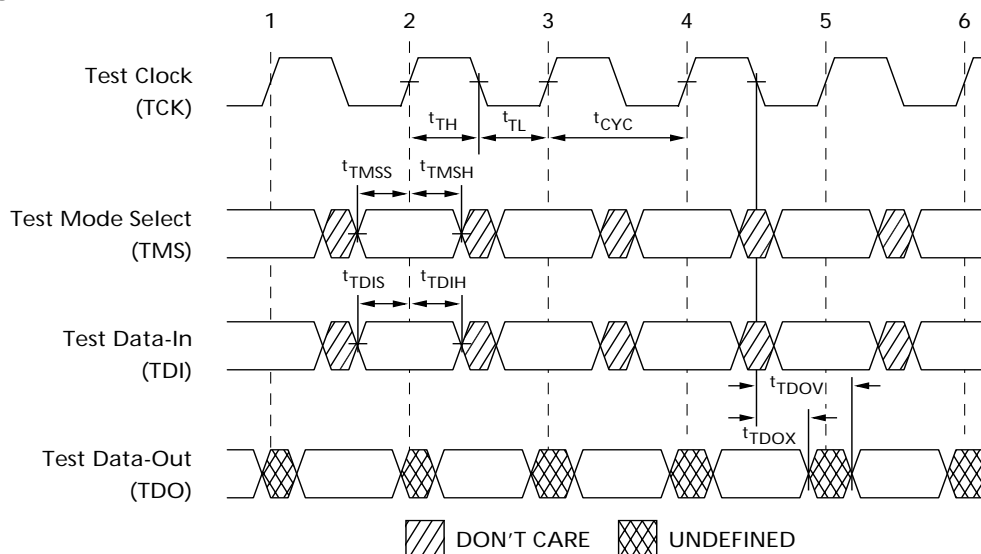

The boundary scan register has a special bit located at bit #89 (for 165-FBGA package) or bit #138 (for 209 BGA package). When this scan cell, called the "extest output bus tri-state," is latched into the preload register during the "Update-DR" state in the TAP controller, it will directly control the state of the output (Q-bus) pins, when the EXTEST is entered as the current instruction. When HIGH, it will enable the output buffers to drive the output bus. When LOW, this bit will place the output bus into a High-Z condition.

This bit can be set by entering the SAMPLE/PRELOAD or EXTEST command, and then shifting the desired bit into that cell, during the "Shift-DR" state. During "Update-DR," the value loaded into that shift-register cell will latch into the preload register. When the EXTEST instruction is entered, this bit will directly control the output Q-bus pins. Note that this bit is preset HIGH to enable the output when the device is powered-up, and also when the TAP controller is in the "Test-Logic-Reset" state.

### Reserved

These instructions are not implemented but are reserved for future use. Do not use these instructions.

## TAP Timing

**TAP AC Switching Characteristics** Over the Operating Range<sup>[9, 10]</sup>

Parameter	Description	Min.	Max.	Unit

I <sub>SB3</sub>	Automatic CE Power-down Current—CMOS Inputs	Max. V <sub>DD</sub> , Device Deselected, V <sub>IN</sub> ≤ 0.3V or V <sub>IN</sub> ≥ V <sub>DDQ</sub> - 0.3V, f = f <sub>MAX</sub> = 1/t <sub>CYC</sub>	4.0-ns cycle, 250 MHz	160	mA
			5.0-ns cycle, 200 MHz	160	mA
			6.0-ns cycle, 167 MHz	160	mA
I <sub>SB4</sub>	Automatic CE Power-down Current—TTL Inputs	Max. V <sub>DD</sub> , Device Deselected, V <sub>IN</sub> ≥ V <sub>IH</sub> or V <sub>IN</sub> ≤ V <sub>IL</sub> , f = 0	All speed grades	110	mA

Shaded areas contain advance information.

**Notes:**

- 14. Overshoot: V<sub>IH</sub>(AC) < V<sub>DD</sub> + 1.5V (Pulse width less than tcyc/2), undershoot: V<sub>IL</sub>(AC) > -2V (Pulse width less than tcyc/2).
- 15. T<sub>Power-up</sub>: Assumes a linear ramp from 0V to V<sub>DD</sub> (min.) within 200ms. During this time V<sub>IH</sub> < V<sub>DD</sub> and V<sub>DDQ</sub> < V<sub>DD</sub>.

**Thermal Resistance<sup>[16]</sup>**

Parameters	Description	Test Conditions	100 TQFP	165 FBGA	209 FBGA	Unit
$\Theta_{JA}$	Thermal Resistance (Junction to Ambient)	Test conditions follow standard test methods and procedures for measuring thermal impedance, per EIA/JESD51.	25.21	20.8	25.31	°C/W
$\Theta_{JC}$	Thermal Resistance (Junction to Case)		2.58	3.2	4.48	°C/W

**Capacitance<sup>[16]</sup>**

Parameter	Description	Test Conditions	100 TQFP	165 FBGA	209 FBGA	Unit
$C_{IN}$	Input Capacitance	$T_A = 25^\circ\text{C}$ , $f = 1\text{ MHz}$ , $V_{DD} = 2.5\text{V}$ $V_{DDQ} = 2.5\text{V}$	6.5	5	5	pF
$C_{CLK}$	Clock Input Capacitance		3	5	5	pF
$C_{I/O}$	Input/Output Capacitance		5.5	7	7	pF

**AC Test Loads and Waveforms**
**2.5V I/O Test Load**

**1.8V I/O Test Load**

**Switching Characteristics Over the Operating Range [ 21, 22]**

Parameter	Description	250		200		167		Unit
		Min.	Max.	Min.	Max.	Min.	Max.	
$t_{Power}^{[17]}$	$V_{CC}$ (typical) to the first access read or write	1		1		1		ms
<b>Clock</b>								
$t_{CYC}$	Clock Cycle Time	4.0		5.0		6.0		ns
$F_{MAX}$	Maximum Operating Frequency		250		200		167	MHz
$t_{CH}$	Clock HIGH	1.5		2.0		2.4		ns
$t_{CL}$	Clock LOW	1.5		2.0		2.4		ns
<b>Output Times</b>								
$t_{CO}$	Data Output Valid After CLK Rise		2.6		3.2		3.4	ns
$t_{EOV}$	OE LOW to Output Valid		2.6		3.0		3.4	ns
$t_{DOH}$	Data Output Hold After CLK Rise	1.0		1.5		1.5		ns
$t_{CHZ}$	Clock to High-Z <sup>[18, 19, 20]</sup>		2.6		3.0		3.4	ns

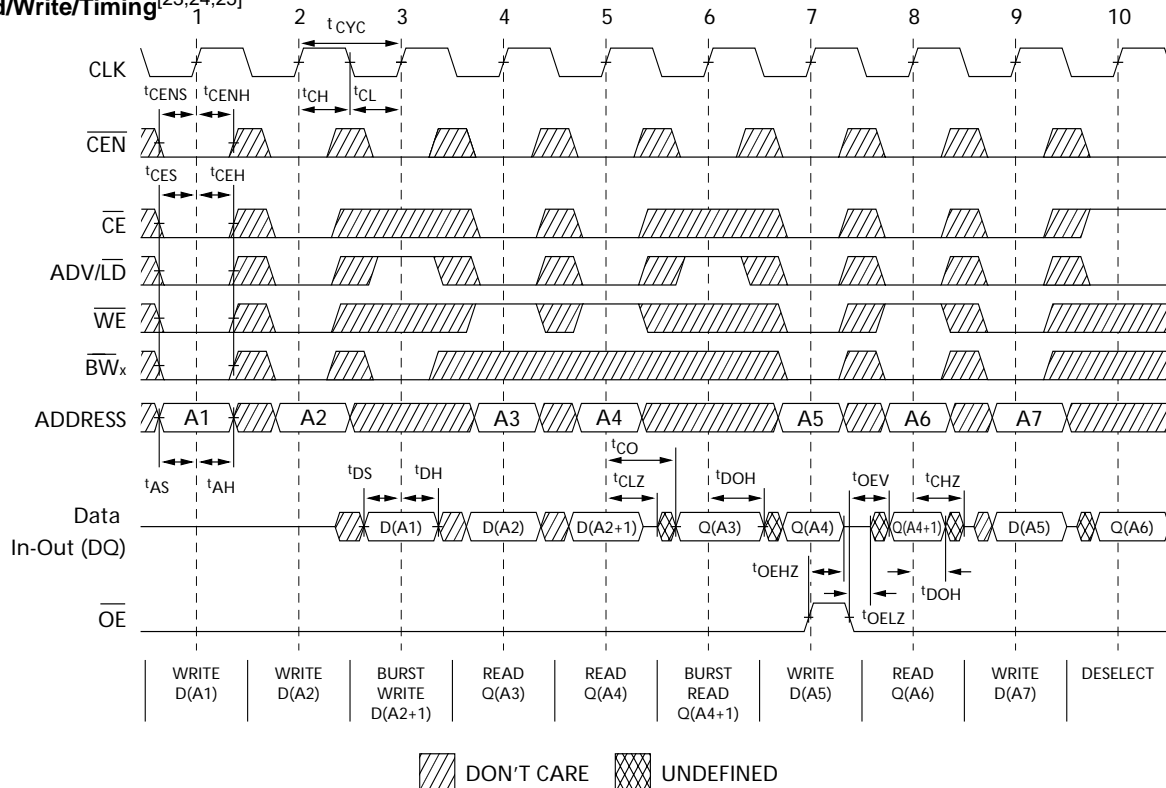

**Notes:**

16. Tested initially and after any design or process changes that may affect these parameters.
17. This part has a voltage regulator internally;  $t_{power}$  is the time power needs to be supplied above  $V_{dd}$  minimum initially, before a Read or Write operation can be initiated.
18.  $t_{CHZ}$ ,  $t_{CLZ}$ ,  $t_{EOLZ}$ , and  $t_{EOHZ}$  are specified with AC test conditions shown in (b) of AC Test Loads. Transition is measured  $\pm 200\text{ mV}$  from steady-state voltage.
19. At any given voltage and temperature,  $t_{EOHZ}$  is less than  $t_{EOLZ}$  and  $t_{CHZ}$  is less than  $t_{CLZ}$  to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve High-Z prior to Low-Z under the same system conditions.
20. This parameter is sampled and not 100% tested.
21. Timing reference is 1.25V when  $V_{DDQ} = 2.5\text{V}$  and 0.9V when  $V_{DDQ} = 1.8\text{V}$ .
22. Test conditions shown in (a) of AC Test Loads unless otherwise noted.

**Switching Characteristics** Over the Operating Range (continued)<sup>[21, 22]</sup>

Parameter	Description	250		200		167		Unit
		Min.	Max.	Min.	Max.	Min.	Max.

Shaded areas contain advance information.

**Switching Waveforms**
**Read/Write/Timing**<sup>[23,24,25]</sup>

**Notes:**

23. For this waveform ZZ is tied low.

 24. When CE is LOW,  $\overline{CE}_1$  is LOW,  $\overline{CE}_2$  is HIGH and  $\overline{CE}_3$  is LOW. When  $\overline{CE}$  is HIGH,  $\overline{CE}_1$  is HIGH or  $\overline{CE}_2$  is LOW or  $\overline{CE}_3$  is HIGH.

25. Order of the Burst sequence is determined by the status of the MODE (0=Linear, 1=Interleaved).Burst operations are optional.

**Switching Waveforms (continued)**
**NOP, STALL and DESELECT Cycles** <sup>[23,24,25]</sup>

**ZZ Mode Timing** <sup>[27,28]</sup>
