MAXIM

3.3V, 12-Bit, 200Msps High Dynamic Performance DAC with CMOS Inputs

General Description

The MAX5883 is an advanced, 12-bit, 200Msps digital-to-analog converter (DAC) designed to meet the demanding performance requirements of signal synthesis applications found in wireless base stations and other communications applications. Operating from a single 3.3V supply, this DAC offers exceptional dynamic performance such as 77dBc spurious-free dynamic range (SFDR) at f_{OUT} = 10MHz. The DAC supports update rates of 200Msps at a power dissipation of less than 200mW.

The MAX5883 utilizes a current-steering architecture, which supports a full-scale output current range of 2mA to 20mA, and allows a differential output voltage swing between 0.1V_{P-P} and 1V_{P-P}.

The MAX5883 features an integrated 1.2V bandgap reference and control amplifier to ensure high accuracy and low noise performance. Additionally, a separate reference input pin enables the user to apply an external reference source for optimum flexibility and to improve gain accuracy.

The digital and clock inputs of the MAX5883 are designed for CMOS-compatible voltage levels. The MAX5883 is available in a 48-pin QFN package with an exposed paddle (EP) and is specified for the extended industrial temperature range (-40°C to +85°C).

Refer to the MAX5884 and MAX5885 data sheets for pin-compatible 14- and 16-bit versions of the MAX5883. For LVDS high-speed versions, refer to the MAX5886, MAX5887, and MAX5888 data sheets.

Applications

Base Stations: Single/Multicarrier UMTS, CDMA

Communications: LMDS, MMDS, Point-to-Point Microwave

Digital Signal Synthesis

Automated Test Equipment (ATE)

Instrumentation

Features

- **200Msps Output Update Rate**
- **Single 3.3V Supply Operation**
- **Excellent SFDR and IMD Performance**
  SFDR = 77dBc at f_{OUT} = 10MHz (to Nyquist)
  IMD = -86dBc at f_{OUT} = 10MHz
  ACLR = 71dB at f_{OUT} = 30.72MHz
- **2mA to 20mA Full-Scale Output Current**
- **CMOS-Compatible Digital and Clock Inputs**
- **On-Chip 1.2V Bandgap Reference**
- **Low Power Dissipation**
- **48-Pin QFN-EP Package**

Pin Description

PIN	NAME	FUNCTION
1, 2, 16, 25–29, 47, 48	N.C.	No connection. **Do not connect to these pins. Do not tie these pins together.**
3	XOR	XOR Input Pin. XOR = 1 inverts the digital input data. XOR = 0 leaves the digital input data unchanged. XOR has an internal pulldown resistor and may be left unconnected if not used.
4, 9	VCLK	Clock Supply Voltage. Accepts a supply voltage range of 3.135V to 3.465V. Bypass each pin with a 0.1µF capacitor to the nearest CLKGND.
5, 8	CLKGND	Clock Ground
6	CLKP	Converter Clock Input. Positive input terminal for the converter clock.
7	CLKN	Complementary Converter Clock Input. Negative input terminal for the converter clock.
10	PD	Power-Down Input. PD pulled high enables the DAC's power-down mode. PD pulled low allows for normal operation of the DAC.
11, 21, 23	AV_{DD}	Analog Supply Voltage. Accepts a supply voltage range of 3.135V to 3.465V. Bypass each pin with a 0.1µF capacitor to the nearest AGND.
12, 17, 20, 22, 24, EP	AGND	Analog Ground. Exposed paddle (EP) must be connected to AGND.
13	REFIO	Reference I/O. Output of the internal 1.2V precision bandgap reference. Bypass with a 0.1µF capacitor to AGND. Can be driven with an external reference source.
14	FSADJ	Full-Scale Adjust Input. This input sets the full-scale output current of the DAC. For 20mA full-scale output current, connect a 2kΩ resistor between FSADJ and DACREF.
15	DACREF	Return Path for the Current Set Resistor. For 20mA full-scale output current, connect a 2kΩ resistor between FSADJ and DACREF.
18	IOUTN	Complementary DAC Output. Negative terminal for differential current output. The full-scale output current range can be set from 2mA to 20mA.
19	IOUTP	DAC Output. Positive terminal for differential current output. The full-scale output current range can be set from 2mA to 20mA.
30	SEL0	Mode Select Input SEL0. This pin has an internal pulldown resistor; it can be left open to disable the segment-shuffling function (see the *Segment Shuffling* section).
31, 43	DV_{DD}	Digital Supply Voltage. Accepts a supply voltage range of 3.135V to 3.465V. Bypass each pin with a 0.1µF capacitor to the nearest DGND.
32, 42	DGND	Digital Ground
33	B11	Data Bit 11 (MSB)
34	B10	Data Bit 10
35	B9	Data Bit 9
36	B8	Data Bit 8
37	B7	Data Bit 7

3.3V, 12-Bit, 200Msps High Dynamic Performance DAC with CMOS Inputs

Pin Description (continued)

PIN	NAME	FUNCTION
38	B6	Data Bit 6
39	B5	Data Bit 5
40	B4	Data Bit 4
41	B3	Data Bit 3

45	B1	Data Bit 1
46	B0	Data Bit 0 (LSB)

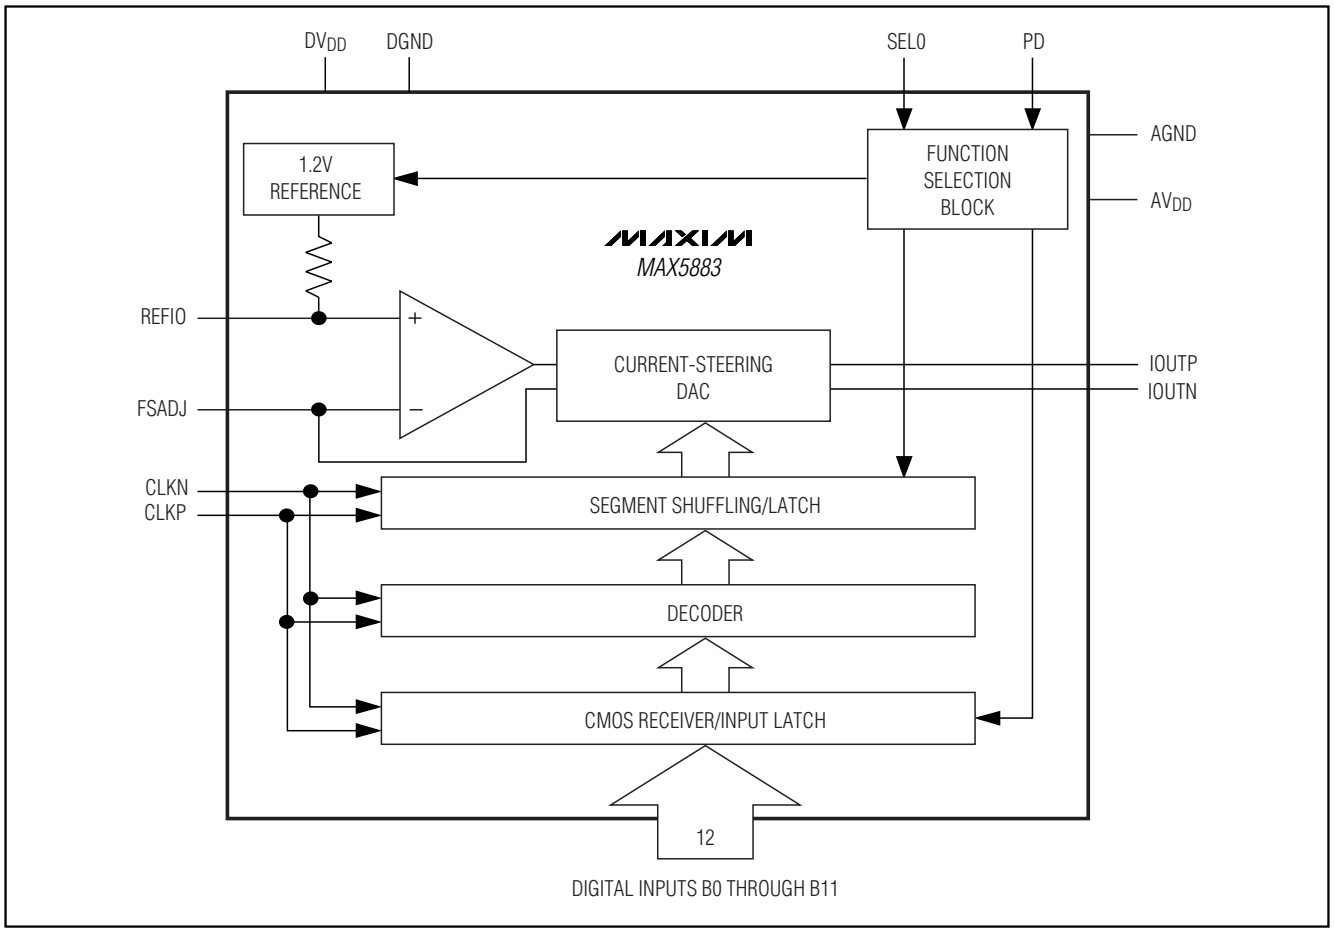

Figure 1. Simplified MAX5883 Block Diagram

3.3V, 12-Bit, 200Msps High Dynamic Performance DAC with CMOS Inputs

Detailed Description

Architecture

The MAX5883 is a high-performance, 12-bit, current-steering DAC (Figure 1) capable of operating with clock speeds up to 200MHz. The converter consists of separate input and DAC registers, followed by a current-steering circuit. This circuit is capable of generating differential full-scale currents in the range of 2mA to 20mA. An internal current-switching network in combination with external 50Ω termination resistors convert the differential output currents into a differential output voltage with a peak-to-peak output voltage range of 0.1V to 1V. An integrated 1.2V bandgap reference, control amplifier, and user-selectable external resistor determine the data converter's full-scale output range.

Reference Architecture and Operation

The MAX5883 supports operation with the on-chip 1.2V bandgap reference or an external reference voltage source. REFIO serves as the input for an external, low-impedance reference source, and as the output if the DAC is operating with the internal reference. For stable operation with the internal reference, REFIO should be decoupled to AGND with a 0.1µF capacitor. Due to its limited output drive capability, REFIO must be buffered with an external amplifier, if heavier loading is required.

The MAX5883's reference circuit (Figure 2) employs a control amplifier, designed to regulate the full-scale current I_{OUT} for the differential current outputs of the DAC. Configured as a voltage-to-current amplifier, the output current can be calculated as follows:

$$I_{OUT} = 32 \times I_{REFIO} - 1\ LSB$$

$$I_{OUT} = 32 \times I_{REFIO} - (I_{OUT} / 2^{12})$$

where I_{REFIO} is the reference output current ($I_{REFIO} = V_{REFIO}/R_{SET}$) and I_{OUT} is the full-scale output current of the DAC. Located between FSADJ and DACREF, R_{SET} is the reference resistor, which determines the amplifier's output current for the DAC. See Table 1 for a matrix of different I_{OUT} and R_{SET} selections.

Analog Outputs (IOUTP, IOUTN)

The MAX5883 outputs two complementary currents (IOUTP, IOUTN) that can be operated in a single-ended or differential configuration. A load resistor can convert these two output currents into complementary single-ended output voltages. The differential voltage existing between IOUTP and IOUTN can also be converted to a single-ended voltage using a transformer or a differential amplifier configuration. If no transformer is used, the output should have a 50Ω termination to the analog ground and a 50Ω resistor between the outputs.

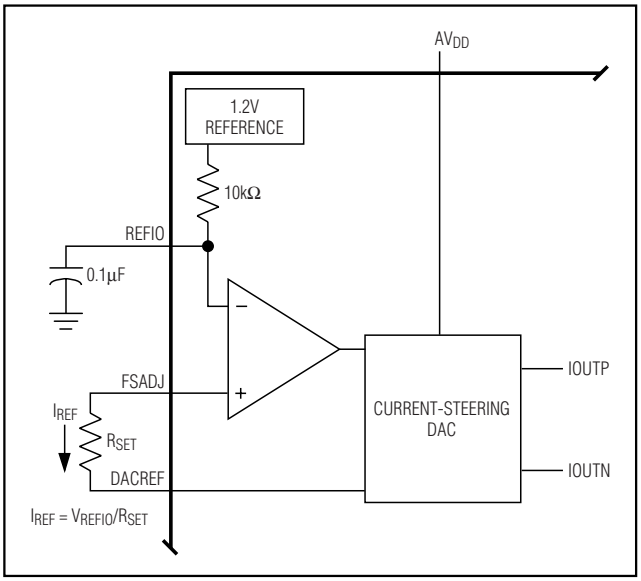

Figure 2. Reference Architecture, Internal Reference Configuration

Table 1. I_{OUT} and R_{SET} Selection Matrix Based on a Typical 1.200V Reference Voltage

FULL-SCALE CURRENT I_{OUT} (mA)	REFERENCE CURRENT I_{REF} (µA)	R_{SET} (kΩ)		OUTPUT VOLTAGE $V_{IOUTP/N}$* (mV_{P-P})

2	62.5	19.2	19.1	100
5	156.26	7.68	7.5	250
10	312.5	3.84	3.83	500
15	468.75	2.56	2.55	750
20	625	1.92	1.91	1000

**Terminated into a 50Ω load.*

3.3V, 12-Bit, 200Msps High Dynamic Performance DAC with CMOS Inputs

Although not recommended because of additional noise pickup from the ground plane, for single-ended operation IOUTP should be selected as the output, with IOUTN connected to AGND. Note that a single-ended output configuration has a higher 2nd-order harmonic distortion at high output frequencies than a differential output configuration.

Figure 3 displays a simplified diagram of the MAX5883's internal output structure.

Clock Inputs (CLKP, CLKN)

The MAX5883 features a flexible differential clock input (CLKP, CLKN) operating from separate supplies (VCLK, CLKGND) to achieve the best possible jitter performance. The two clock inputs can be driven from a single-ended or a differential clock source. For single-ended operation, CLKP should be driven by a logic source, while CLKN should be bypassed to AGND with a 0.1µF capacitor.

The CLKP and CLKN pins are internally biased to VCLK/2. This allows the user to AC-couple clock sources directly to the device without external resistors to define the DC level. The input resistance of CLKP and CLKN is >5kΩ.

See Figure 4 for a convenient and quick way to apply a differential signal created from a single-ended source (e.g., HP 8662A signal generator) and a wideband transformer. These inputs can also be driven from a CMOS-compatible clock source; however, it is recommended to use sinewave or AC-coupled ECL drive for best performance.

Data Timing Relationship

Figure 5 shows the timing relationship between differential, digital CMOS data, clock, and output signals. The MAX5883 features a 1.25ns hold, a 0.4ns setup, and a 1.8ns propagation delay time. There is a 3.5 clock-cycle latency between CLKP/CLKN transitioning high/low and IOUTP/IOUTN.

CMOS-Compatible Digital Inputs (B0–B11)

The MAX5883 features single-ended, CMOS-compatible receivers on the bus input interface. These CMOS inputs (B0–B11) allow for a voltage swing of 3.3V.

Segment Shuffling (SEL0)

Segment shuffling can improve the SFDR of the MAX5883 at higher output frequencies and amplitudes. Note that an improvement in SFDR can only be achieved at the cost of a slight increase in the DAC's noise floor.

Pin SEL0 controls the segment-shuffling function. If SEL0 is pulled low, the segment-shuffling function of the DAC is disabled. SEL0 can also be left open, because an internal pulldown resistor helps to deactivate the segment-shuffling feature. To activate the MAX5883 segment-shuffling function, SEL0 must be pulled high.

XOR Function (XOR)

The MAX5883 is equipped with a single-ended, CMOS-compatible XOR input, which may be left open (XOR provides an internal pulldown resistor) or pulled down to DGND, if not used. Input data is XORed with the bit applied to the XOR pin. Pulling XOR high inverts the input data. Pulling XOR low leaves the input data noninverted. By applying a pseudorandom bit stream to XOR and applying inverted data when XOR is high, the bit transitions of the digital input data can be decorrelated from the DAC output. This allows the user to troubleshoot possible spurious or harmonic distortion degradation due to digital feedthrough on the PC board.

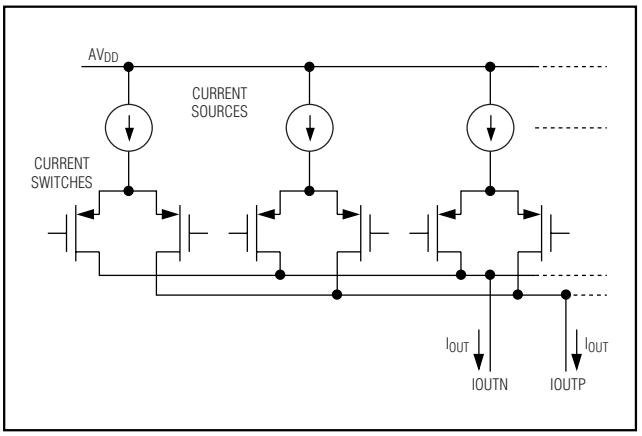

Figure 3. Simplified Analog Output Structure

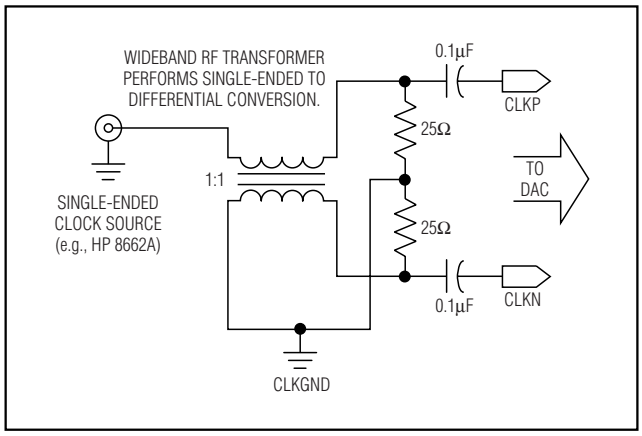

Figure 4. Differential Clock Signal Generation

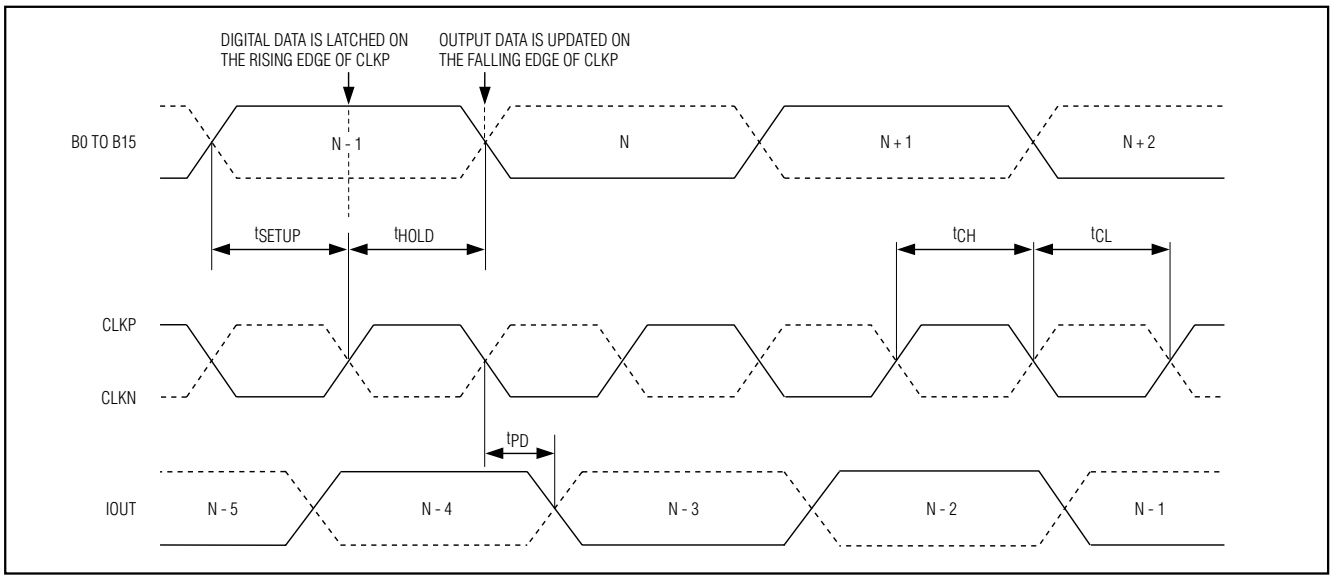

Figure 5. Detailed Timing Relationship

Power-Down Operation (PD)

The MAX5883 also features an active-high power-down mode, which allows the user to cut the DAC's current consumption. A single pin (PD) is used to control the power-down mode (PD = 1) or reactivate the DAC (PD = 0) after power-down.

Enabling the power-down mode of this 12-bit CMOS DAC allows the overall power consumption to be reduced to less than 1mW. The MAX5883 requires 10ms to wake up from power-down and enter a fully operational state.

Applications Information

Differential Coupling Using a Wideband RF Transformer

The differential voltage existing between IOUTP and IOUTN can also be converted to a single-ended voltage using a transformer (Figure 6) or a differential amplifier configuration. Using a differential transformer-coupled output, in which the output power is limited to 0dBm, can optimize the dynamic performance. However, make sure to pay close attention to the transformer core saturation characteristics when selecting a transformer for the MAX5883. Transformer core saturation can introduce strong 2nd-harmonic distortion, especially at low output frequencies and high signal amplitudes. It is also recommended to center tap the transformer to ground. If no transformer is used, each DAC output should be terminated to ground with a 50Ω resistor. Additionally, a 100Ω resistor should be placed between the outputs.

If a single-ended unipolar output is desirable, IOUTP should be selected as the output, with IOUTN grounded. However, driving the MAX5883 single ended is not recommended since additional noise is added (from the ground plane) in such configurations.

The distortion performance of the DAC depends on the load impedance. The MAX5883 is optimized for a 50Ω double termination. It can be used with a transformer output as shown in Figure 7 or just one 50Ω resistor from each output to ground and one 50Ω resistor between the outputs. This produces a full-scale output power of up to 0dBm, depending on the output current setting. Higher termination impedance can be used at the cost of degraded distortion performance and increased output noise voltage.

Adjacent Channel Leakage Power Ratio (ACLR) Testing for CDMA- and W-CDMA-Based Base Station Transceiver Systems (BTS)

The transmitter sections of BTS applications serving CDMA and W-CDMA architectures must generate carriers with minimal coupling of carrier energy into the adjacent channels. A transmit mask (Tx mask) exists for this application. The spread-spectrum modulation function applied to the carrier frequency generates a spectral response, which is uniform over a given bandwidth (up to 4MHz) for a W-CDMA-modulated carrier.

3.3V, 12-Bit, 200Msps High Dynamic Performance DAC with CMOS Inputs

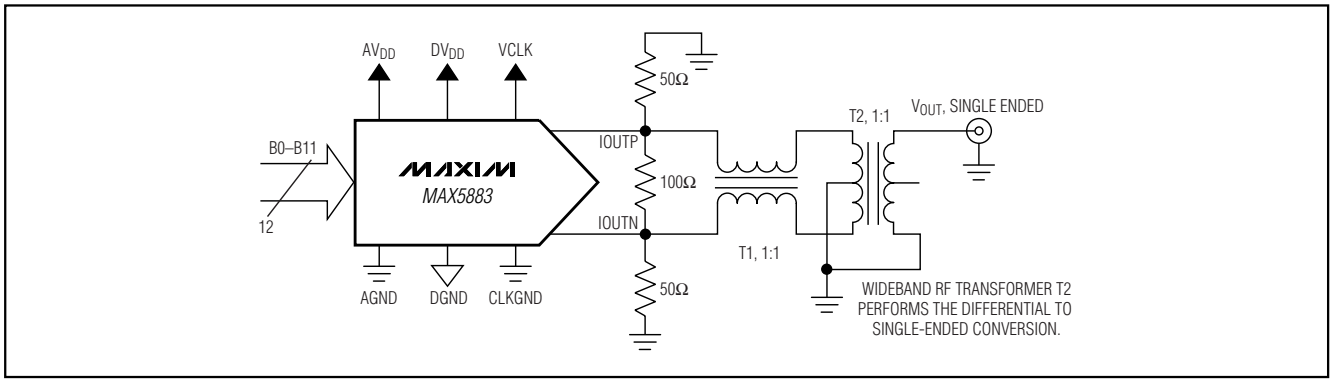

Figure 6. Differential to Single-Ended Conversion Using a Wideband RF Transformer

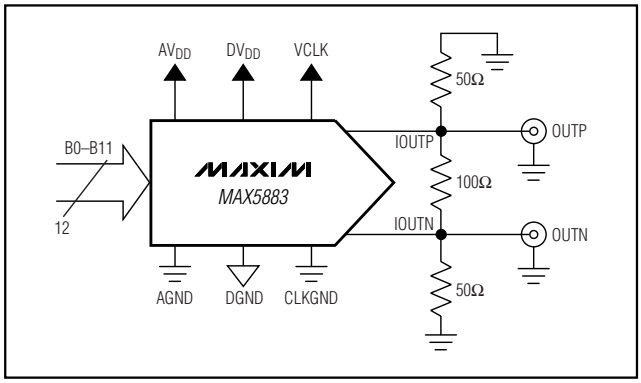

Figure 7. MAX5883 Differential Output Configuration

A dominant specification is ACLR, a parameter which reflects the ratio of the power in the desired carrier band to the power in an adjacent carrier band. The specification covers the first two adjacent bands, and is measured on both sides of the desired carrier.

According to the transmit mask for CDMA and W-CDMA architectures, the power ratio of the integrated carrier channel energy to the integrated adjacent channel energy must be >45dB for the first adjacent carrier slot (ACLR 1) and >50dB for the second adjacent carrier slot (ACLR 2). This specification applies to the output of the entire transmitter signal chain. The requirement for only the DAC block of the transmitter must be tighter, with a typical margin of >15dB, requiring the DAC's ACLR 1 to be better than 60dB.

Adjacent channel leakage is caused by a single spread-spectrum carrier, which generates intermodulation (IM) products between the frequency components located within the carrier band. The energy at one end of the carrier band generates IM products with the energy from the opposite end of the carrier band. For single-carrier W-CDMA modulation, these IMD products are spread 3.84MHz over the adjacent sideband. Four contiguous W-CDMA carriers spread their IM products over a bandwidth of 20MHz on either side of the 20MHz total carrier bandwidth. In this four-carrier scenario, only the energy in the first adjacent 3.84MHz sideband is considered for ACLR 1. To measure ACLR, drive the converter with a W-CDMA pattern. Make sure that the signal is backed off by the peak-to-average ratio, such that the DAC is not clipping the signal. ACLR can then be measured with the ACLR measurement function built into your spectrum analyzer.

Figure 8 shows the ACLR performance for a single W-CDMA carrier (f_{CLK} = 184.32MHz, f_{OUT} = 30.72MHz) applied to the MAX5883 (including measurement system limitations*).

Figure 9 illustrates the ACLR test results for the MAX5883 with a four-carrier W-CDMA signal at an output frequency of 30.72MHz and a sampling frequency of 184.32MHz. Considerable care must be taken to ensure accurate measurement of this parameter.

Grounding, Bypassing, and Power-Supply Considerations

Grounding and power-supply decoupling can strongly influence the performance of the MAX5883. Unwanted digital crosstalk may couple through the input, reference, power supply, and ground connections, affecting dynamic performance. Proper grounding and power-

**Note that due to their own IM effects and noise limitations, spectrum analyzers introduce ACLR errors, which can falsify the measurement. For a single-carrier ACLR measurement greater than 70dB, these measurement limitations are significant, becoming even more restricting for multicarrier measurement. Before attempting an ACLR measurement, it is recommended consulting application notes provided by major spectrum analyzer manufacturers that provide useful tips on how to use their instruments for such tests.*

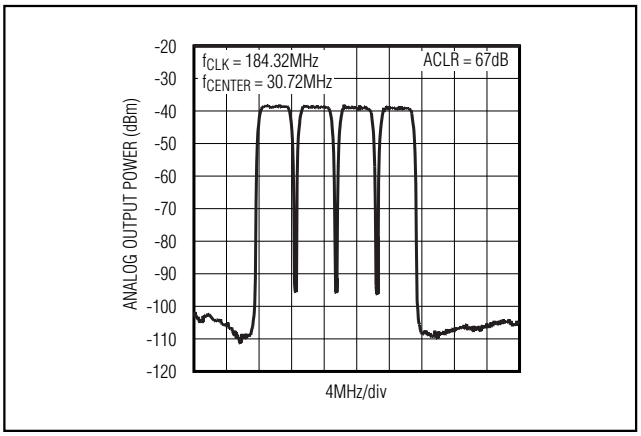

Figure 9. ACLR for W-CDMA Modulation, Four Carriers

supply decoupling guidelines for high-speed, high-frequency applications should be closely followed. This reduces EMI and internal crosstalk that can significantly affect the dynamic performance of the MAX5883.

Use of a multilayer printed circuit (PC) board with separate ground and power-supply planes is recommended. High-speed signals should run on lines directly above the ground plane. Since the MAX5883 has separate analog and digital ground buses (AGND, CLKGND, and DGND, respectively), the PC board should also have separate analog and digital ground sections with only one point connecting the two planes. Digital signals should be run above the digital ground plane and analog/clock signals above the analog/clock ground plane. Digital signals should be kept as far away from sensitive analog inputs, reference input sense lines, common-mode input, and clock inputs as practical. A symmetric design of clock input and analog output lines is recommended to minimize 2nd-order harmonic distortion components and optimize the DAC's dynamic performance. Digital signal paths should be kept short and run lengths matched to avoid propagation delay and data skew mismatches.

The MAX5883 supports three separate power-supply inputs for analog (AV_{DD}), digital (DV_{DD}), and clock (VCLK) circuitry. Each AV_{DD}, DV_{DD}, and VCLK input should at least be decoupled with a separate 0.1µF capacitor as close to the pin as possible and their opposite ends with the shortest possible connection to the corresponding ground plane (Figure 10). All three power-supply voltages should also be decoupled at the point they enter the PC board with tantalum or electrolytic capacitors. Ferrite beads with additional decoupling capacitors forming a pi network could also improve performance.

The analog and digital power-supply inputs AV_{DD}, VCLK, and DV_{DD} of the MAX5883 allow a supply voltage range of 3.3V ±5%.

The MAX5883 is packaged in a 48-pin QFN-EP (package code: G4877-1), providing greater design flexibility, increased thermal efficiency**, and optimized AC performance of the DAC. The exposed pad (EP) enables the user to implement grounding techniques, which are necessary to ensure highest performance operation. **The EP must be soldered down to AGND.**

In this package, the data converter die is attached to an EP lead frame with the back of this frame exposed at the package bottom surface, facing the PC board side of the package. This allows a solid attachment of the package to the PC board with standard infrared (IR) flow soldering techniques. A specially created land pattern on the PC board, matching the size of the EP (5mm × 5mm), ensures the proper attachment and grounding of the DAC. Designing vias*** into the land area and implementing large ground planes in the PC board design allow for highest performance operation of the DAC. An array of at least 3 × 3 vias (≤0.3mm diameter per via hole and 1.2mm pitch between via holes) is recommended for this 48-pin QFN-EP package.

***Thermal efficiency is not the key factor, since the MAX5883 features low-power operation. The exposed pad is the key element to ensure a solid ground connection between the DAC and the PC board's analog ground layer.*

****Vias connect the land pattern to internal or external copper planes. It is important to connect as many vias as possible to the analog ground plane to minimize inductance.*

3.3V, 12-Bit, 200Msps High Dynamic Performance DAC with CMOS Inputs

Static Performance Parameter Definitions

Integral Nonlinearity (INL)

Integral nonlinearity is the deviation of the values on an actual transfer function from either a best straight line fit (closest approximation to the actual transfer curve) or a line drawn between the end points of the transfer function, once offset and gain errors have been nullified. For a DAC, the deviations are measured at every individual step.

Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between an actual step height and the ideal value of 1 LSB. A DNL error specification of less than 1 LSB guarantees no missing codes and a monotonic transfer function.

Offset Error

The offset error is the difference between the ideal and the actual offset current. For a DAC, the offset point is the average value at the output for the two midscale digital input codes with respect to the full scale of the DAC. This error affects all codes by the same amount.

Gain Error

A gain error is the difference between the ideal and the actual full-scale output voltage on the transfer curve, after nullifying the offset error. This error alters the slope of the transfer function and corresponds to the same percentage error in each step.

Settling Time

The settling time is the amount of time required from the start of a transition until the DAC output settles its new output value to within the converter's specified accuracy.

Glitch Energy

A glitch is generated when a DAC switches between two codes. The largest glitch is usually generated around the midscale transition, when the input pattern transitions from 011...111 to 100...000. The glitch energy is found by integrating the voltage of the glitch at the midscale transition over time. The glitch energy is usually specified in pV-s.

Dynamic Performance Parameter Definitions

Signal-to-Noise Ratio (SNR)

For a waveform perfectly reconstructed from digital samples, the theoretical maximum SNR is the ratio of the full-scale analog output (RMS value) to the RMS quantization error (residual error). The ideal, theoretical maximum SNR can be derived from the DAC's resolution (N bits):

$$SNR_{dB} = 6.02_{dB} \times N + 1.76_{dB}$$

However, noise sources such as thermal noise, reference noise, clock jitter, etc., affect the ideal reading; therefore, SNR is computed by taking the ratio of the RMS signal to the RMS noise, which includes all spectral components minus the fundamental, the first four harmonics, and the DC offset.

Spurious-Free Dynamic Range (SFDR)

SFDR is the ratio of RMS amplitude of the carrier frequency (maximum signal components) to the RMS value of their next-largest distortion component. SFDR is usually measured in dBc and with respect to the carrier frequency amplitude or in dB FS with respect to the DAC's full-scale range. Depending on its test condition, SFDR is observed within a predefined window or to Nyquist.

Two-/Four-Tone Intermodulation Distortion (IMD)

The two-tone IMD is the ratio expressed in dBc (or dB FS) of either input tone to the worst 3rd-order (or higher) IMD products. Note that 2nd-order IMD products usually fall at frequencies that can be easily removed by digital filtering; therefore, they are not as critical as 3rd-order IMDs. The two-tone IMD performance of the MAX5883 was tested with the two individual input tone levels set to at least -6dB FS and the four-tone performance was tested at an output frequency of 32MHz and amplitude of -12dB FS.

Adjacent Channel Leakage Power Ratio (ACLR)

Commonly used in combination with W-CDMA, ACLR reflects the leakage power ratio in dB between the measured power within a channel relative to its adjacent channel. ACLR provides a quantifiable method of determining out-of-band spectral energy and its influence on an adjacent channel when a bandwidth-limited RF signal passes through a nonlinear device.

NOTES:

1. DIE THICKNESS ALLOWABLE IS 0.305mm MAXIMUM (.012 INCHES MAXIMUM).
2. DIMENSIONING & TOLERANCES CONFORM TO ASME Y14.5M. - 1994.
3. N IS THE NUMBER OF TERMINALS.
   Nd IS THE NUMBER OF TERMINALS IN X-DIRECTION & Ne IS THE NUMBER OF TERMINALS IN Y-DIRECTION.
4. DIMENSION b APPLIES TO PLATED TERMINAL AND IS MEASURED BETWEEN 0.20 AND 0.25mm FROM TERMINAL TIP.
5. THE PIN #1 IDENTIFIER MUST EXIST ON THE TOP SURFACE OF THE PACKAGE BY USING INDENTATION MARK OR INK/LASER MARKED. DETAILS OF PIN #1 IDENTIFIER IS OPTIONAL, BUT MUST BE LOCATED WITHIN ZONE INDICATED.
6. EXACT SHAPE AND SIZE OF THIS FEATURE IS OPTIONAL.
7. ALL DIMENSIONS ARE IN MILLIMETERS.
8. PACKAGE WARPAGE MAX 0.08mm.
9. APPLIED FOR EXPOSED PAD AND TERMINALS. EXCLUDE EMBEDDED PART OF EXPOSED PAD FROM MEASURING.
10. MEETS JEDEC MO220 EXCEPT DIMENSION "b" MINIMUM.
11. APPLY ONLY FOR TERMINAL.
12. THIS PACKAGE OUTLINE APPLIES TO ANVIL SINGULATION(STEPPED SIDES).
