

Blackfin® Embedded Processor

Preliminary Technical Data

ADSP-BF542/BF544/BF547/BF548/BF549

FEATURES

Up to 600 MHz High-Performance Blackfin Processor
Two 16-Bit MACs, Two 40-Bit ALUs, Four 8-Bit Video ALUs
RISC-Like Register and Instruction Model

0.9 V to 1.3 V Core VDD with On-chip Voltage Regulation2.5 V and 3.3 V-Tolerant I/O with Specific 5V-Tolerant Pins400-ball Lead-Free mBGA and 360-ball Lead-Free pBGA package options.

MEMORY

Up to 324K bytes of on-chip memory comprised of: Instruction SRAM/cache; instruction SRAM; data SRAM/cache; additional dedicated data SRAM; scratchpad SRAM (see Table 1 on Page 3 for available memory configurations

External Sync Memory Controller Supporting DDR/Mobile DDR SDRAM

External Async Memory Controller Supporting 8/16 bit Async Memories and Burst Flash Devices

NAND Flash Controller

Four Memory-to-Memory DMA pairs, two with ext. requests Memory Management Unit Providing Memory Protection Flexible Booting Options

Code Security with Lockbox™ Secure Technology One-Time-Programmable (OTP) Memory

PERIPHERALS

High-Speed USB On-the-Go (OTG) with Integrated PHY SD/SDIO Controller

ATA/ATAPI-6 Controller

Up to four Synchronous Serial Ports (SPORTs)

Up to three Serial Peripheral Interfaces (SPI-Compatible)
Up to four UARTs, two with Automatic Hardware Flow

Control

Up to two CAN (Controller Area Network) 2.0B Interfaces Up to two TWI (Two-Wire Interface) Controllers

8- or 16-Bit Asynchronous Host DMA Interface

Multiple Enhanced Parallel Peripheral Interfaces (EPPIs), Supporting ITU-R BT.656 Video Formats and 18/24-bit LCD Connections

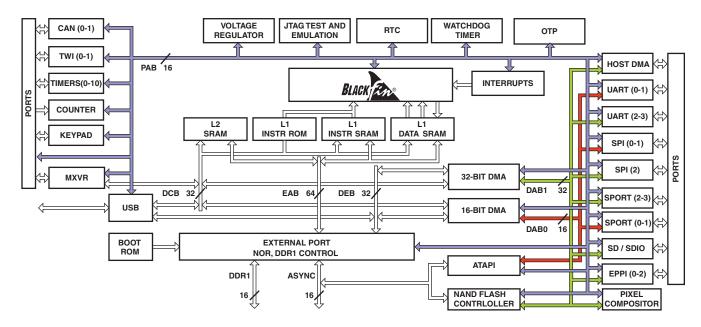

Media Transceiver (MXVR) for connection to a MOST® Network

Pixel Compositor for overlays, alpha blending, and color conversion

Up to eleven 32-Bit Timers/Counters with PWM Support Real-Time Clock (RTC) and Watchdog Timer Up/Down Counter With Support for Rotary Encoder

Up to 152 General Purpose I/O (GPIOs)

On-Chip PLL Capable of 0.5x to 64x Frequency Multiplication Debug/JTAG Interface

REVISION HISTORY

Revision PrG: Corrections and additions to PrF:

• Addition of DDR and Mobile DDR Timing parameters.

GENERAL DESCRIPTION

The ADSP-BF542/4/7/8/9 processors are members of the Blackfin family of products, incorporating the Analog Devices/Intel Micro Signal Architecture (MSA). Blackfin processors combine a dual-MAC state-of-the-art signal processing engine, the advantages of a clean, orthogonal RISC-like microprocessor instruction set, and single-instruction, multiple-data (SIMD) multimedia capabilities into a single instruction-set architecture.

Specific performance and memory configurations for ADSP-BF542/4/7/8/9 processors are shown in Table 1.

 $^{^1\,\}mathrm{CAN}$ on the ADSP-BF544 and ADSP-BF542 is only available on automotive grade devices.

Specific peripherals for ADSP-BF542/4/7/8/9 processors are shown in Table 2.

¹ Automotive Only.

² This ROM is not customer configurable.

The ADSP-BF542/4/7/8/9 processors are completely code and pin compatible. They differ only with respect to their performance, on-chip memory, and selection of I/O peripherals. Specific performance, memory, and feature configurations, are shown in Table 1.

By integrating a rich set of industry-leading system peripherals and memory, Blackfin processors are the platform of choice for next-generation applications that require RISC-like programmability, multimedia support and leading-edge signal processing in one integrated package.

LOW-POWER ARCHITECTURE

Blackfin processors provide world-class power management and performance. Blackfin processors are designed in a low power and low voltage design methodology and feature on-chip dynamic power management, the ability to vary both the voltage and frequency of operation to significantly lower overall power consumption. Varying the voltage and frequency can result in a substantial reduction in power consumption, compared with just varying the frequency of operation. This translates into longer battery life for portable appliances.

SYSTEM INTEGRATION

The ADSP-BF542/4/7/8/9 processors are highly integrated system-on-a-chip solutions for the next generation of embedded network connected applications. By combining industry-standard interfaces with a high performance signal processing core, users can develop cost-effective solutions quickly without the need for costly external components. The system peripherals include a high speed USB OTG (On-The-Go) controller with integrated PHY, CAN 2.0B controllers, TWI controllers, UART ports, SPI ports, serial ports (SPORTs), ATAPI controller, SD/SDIO controller, a real-time clock, a watchdog timer, LCD controller, and multiple enhanced parallel peripheral interfaces.

ADSP-BF542/4/7/8/9 PROCESSOR PERIPHERALS

The ADSP-BF542/4/7/8/9 processor contains a rich set of peripherals connected to the core via several high bandwidth buses, providing flexibility in system configuration as well as excellent overall system performance (see Figure 1 on Page 1). The general-purpose peripherals include functions such as UARTs, SPI, TWI, timers with pulse width modulation (PWM) and pulse measurement capability, general purpose I/O pins, a real-time clock, and a watchdog timer. This set of functions satisfies a wide variety of typical system support needs and is augmented by the system expansion capabilities of the part. The ADSP-BF542/4/7/8/9 processor contains dedicated network communication modules and high-speed serial and parallel ports, an interrupt controller for flexible management of interrupts from the on-chip peripherals or external sources, and power management control functions to tailor the performance and power characteristics of the processor and system to many application scenarios.

All of the peripherals, except for general-purpose I/O, CAN, TWI, real-time clock, and timers, are supported by a flexible DMA structure. There are also separate memory DMA channels dedicated to data transfers between the processor's various

memory spaces, including external DDR and asynchronous memory. Multiple on-chip buses running at up to 133 MHz provide enough bandwidth to keep the processor core running along with activity on all of the on-chip and external peripherals.

The ADSP-BF542/4/7/8/9 processor includes an on-chip voltage regulator in support of the ADSP-BF542/4/7/8/9 processor dynamic power management capability. The voltage regulator provides a range of core voltage levels when supplied from a single 2.70 V to 3.6 V input. The voltage regulator can be bypassed at the user's discretion.

BLACKFIN PROCESSOR CORE

As shown in Figure 2 on Page 5, the Blackfin processor core contains two 16-bit multipliers, two 40-bit accumulators, two 40-bit ALUs, four video ALUs, and a 40-bit shifter. The computation units process 8-bit, 16-bit, or 32-bit data from the register

The compute register file contains eight 32-bit registers. When performing compute operations on 16-bit operand data, the register file operates as 16 independent 16-bit registers. All operands for compute operations come from the multiported register file and instruction constant fields.

Each MAC can perform a 16-bit by 16-bit multiply in each cycle, accumulating the results into the 40-bit accumulators. Signed and unsigned formats, rounding, and saturation are supported.

The ALUs perform a traditional set of arithmetic and logical operations on 16-bit or 32-bit data. In addition, many special instructions are included to accelerate various signal processing tasks. These include bit operations such as field extract and population count, modulo 2^{32} multiply, divide primitives, saturation and rounding, and sign/exponent detection. The set of video instructions include byte alignment and packing operations, 16-bit and 8-bit adds with clipping, 8-bit average operations, and 8-bit subtract/absolute value/accumulate (SAA) operations. Also provided are the compare/select and vector search instructions.

For certain instructions, two 16-bit ALU operations can be performed simultaneously on register pairs (a 16-bit high half and 16-bit low half of a compute register). By also using the second ALU, quad 16-bit operations are possible.

The 40-bit shifter can perform shifts and rotates and is used to support normalization, field extract, and field deposit instructions.

The program sequencer controls the flow of instruction execution, including instruction alignment and decoding. For program flow control, the sequencer supports PC relative and indirect conditional jumps (with static branch prediction), and subroutine calls. Hardware is provided to support zero-overhead looping. The architecture is fully interlocked, meaning that the programmer need not manage the pipeline when executing instructions with data dependencies.

The address arithmetic unit provides two addresses for simultaneous dual fetches from memory. It contains a multiported register file consisting of four sets of 32-bit index, modify,

length, and base registers (for circular buffering), and eight additional 32-bit pointer registers (for C-style indexed stack manipulation).

Blackfin processors support a modified Harvard architecture in combination with a hierarchical memory structure. Level 1 (L1) memories are those that typically operate at the full processor speed with little or no latency. At the L1 level, the instruction memory holds instructions only. The two data memories hold data, and a dedicated scratchpad data memory stores stack and local variable information.

In addition, multiple L1 memory blocks are provided, offering a configurable mix of SRAM and cache. The memory management unit (MMU) provides memory protection for individual tasks that may be operating on the core and can protect system registers from unintended access.

The architecture provides three modes of operation: user mode, supervisor mode, and emulation mode. User mode has restricted access to certain system resources, thus providing a protected software environment, while supervisor mode has unrestricted access to the system and core resources.

The Blackfin processor instruction set has been optimized so that 16-bit opcodes represent the most frequently used instructions, resulting in excellent compiled code density. Complex DSP instructions are encoded into 32-bit opcodes, representing fully featured multifunction instructions. Blackfin processors support a limited multi-issue capability, where a 32-bit instruction can be issued in parallel with two 16-bit instructions, allowing the programmer to use many of the core resources in a single instruction cycle.

The Blackfin processor assembly language uses an algebraic syntax for ease of coding and readability. The architecture has been optimized for use in conjunction with the C/C++ compiler, resulting in fast and efficient software implementations.

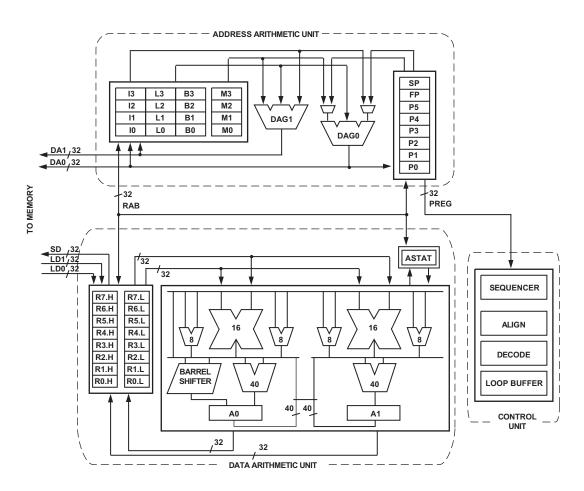

Figure 2. Blackfin Processor Core

MEMORY ARCHITECTURE

The ADSP-BF542/4/7/8/9 processor views memory as a single unified 4G byte address space, using 32-bit addresses. All

resources, including internal memory, external memory, and I/O control registers, occupy separate sections of this common address space. The memory portions of this address space are

arranged in a hierarchical structure to provide a good cost/performance balance of some very fast, low-latency on-chip memory as cache or SRAM, and larger, lower-cost and performance off-chip memory systems. See Figure 3 on Page 6.

The on-chip L1 memory system is the highest-performance memory available to the Blackfin processor. The off-chip memory system, accessed through the external bus interface unit (EBIU), provides expansion with flash memory, SRAM, and double-rate SDRAM (DDR1), optionally accessing up to 516M bytes of physical memory.

Most of the ADSP-BF542/4/7/8/9 processors also include an L2 SRAM memory array which provides up to 128K bytes of high speed SRAM operating at one half the frequency of the core, and slightly longer latency than the L1 memory banks (For information on L2 memory in each processor, see Table 1.) The L2 memory is a unified instruction and data memory and can hold any mixture of code and data required by the system design. The Blackfin cores share a dedicated low latency 64-bit wide data path port into the L2 SRAM memory.

The memory DMA controllers (DMAC1 and DMAC0) provides high-bandwidth data-movement capability. They can perform block transfers of code or data between the internal memory and the external memory spaces.

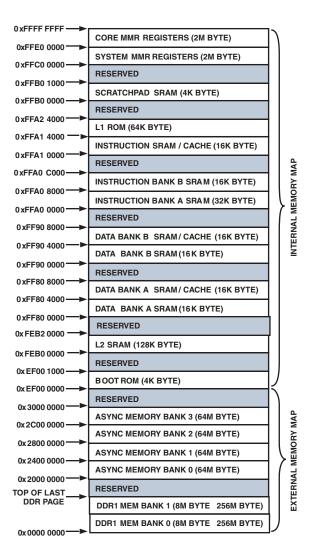

Figure 3. ADSP-BF547BF548/BF549 Internal/External Memory Map

Internal (On-Chip) Memory

The ADSP-BF542/4/7/8/9 processor has several blocks of onchip memory providing high-bandwidth access to the core.

The first block is the L1 instruction memory, consisting of 48K bytes SRAM, and also 16K bytes that can be configured as a four-way set-associative cache or SRAM. This memory is accessed at full processor speed.

The second on-chip memory block is the L1 data memory, consisting of 64K bytes SRAM, of which 32K bytes can be configured as a two-way set associative cache. This memory block is accessed at full processor speed.

¹ This memory map applies to all ADSP-BF542/4/7/8/9 processors, except for L2 memory population. ADSP-BF544 includes 64K Byte of L2 memory: 0xFEB0 0000 - 0xFEB0 FFFF. ADSP-BF542 includes no L2 memory. See also Table 1.

The third memory block is a 4K byte scratchpad SRAM which runs at the same speed as the L1 memories, but is only accessible as data SRAM and cannot be configured as cache memory.

The fourth memory block is the factory programmed L1 instruction ROM, operating at full processor speed. This ROM is not customer configurable.

The fifth memory block is the L2 SRAM, providing 128K bytes of unified instruction and data memory, operating at one half the frequency of the core.

Finally, there is a 4K boot ROM connected as L3 memory. It operates at full SCLK rate.

External (Off-Chip) Memory

Through the External Bus Interface Unit (EBIU) the ADSP-BF542/4/7/8/9 processors provide glueless connectivity to external 16-bit wide memories, such as DDR SDRAM, Mobile DDR, SRAM, NOR flash, NAND flash, and FIFO devices. To provide the best performance, the bus system of the DDR interface is completely separate from the other parallel interfaces.

The DDR/Mobile DDR memory controller can gluelessly manage up to two banks of double-rate synchronous dynamic memory (DDR1 SDRAM). The 16-bit wide interface operates at SCLK frequency, enabling maximum throughput of 532 Mbyte/s. The DDR controller is augmented with a queuing mechanism that performs efficient bursts into the DDR. The controller is an industry standard DDR1 SDRAM controller with each bank supporting from 64 Mbit to 512 Mbit device sizes and 4-, 8-, or 16-bit widths. The controller supports up to 256 Mbytes per external bank. With 2 external banks, the controller supports up to 512 Mbytes total. Each bank is independently programmable and is contiguous with adjacent banks regardless of the sizes of the different banks or their placement.

Traditional 16-bit asynchronous memories, such as SRAM, EPROM, and flash devices, can be connected to one of the four 64 MByte asynchronous memory banks, represented by four memory select strobes. Alternatively, these strobes can function as bank-specific read or write strobes preventing further glue logic when connecting to asynchronous FIFO devices.

In addition, the external bus can connect to advanced flash device technologies, such as:

- Page-mode NOR flash devices
- · Synchronous burst-mode NOR flash devices
- NAND flash devices

NAND Flash Controller (NFC)

The ADSP-BF542/4/7/8/9 provides a NAND Flash Controller (NFC) as part of the external bus interface. NAND flash devices provide high-density, low-cost memory. However, NAND flash devices also have long random access times, invalid blocks, and lower reliability over device lifetimes. Because of this, NAND flash is often used for read-only code storage. In this case, all DSP code can be stored in NAND flash and then transferred to a faster memory (such as DDR or SRAM) before execution.

Another common use of NAND flash is for storage of multimedia files or other large data segments. In this case, a software file system may be used to manage reading and writing of the NAND flash device. The file system selects memory segments for storage with the goal of avoiding bad blocks and equally distributing memory accesses across all address locations. Hardware features of the NFC include:

- Support for page program, page read, and block erase of NAND flash devices, with accesses aligned to page boundaries.
- Error checking and correction (ECC) hardware that facilitates error detection and correction.
- A single 8-bit or 16-bit external bus interface for commands, addresses and data.
- Support for SLC (single level cell) NAND flash devices unlimited in size, with page sizes of 256 and 512 bytes. Larger page sizes can be supported in software.
- Capability of releasing external bus interface pins during long accesses.
- Support for internal bus requests of 16 or 32 bits.
- DMA engine to transfer data between internal memory and NAND flash device.

One-time-Programmable Memory

The ADSP-BF542/4/7/8/9 has 64K bits of one-time programmable (OTP) non-volatile memory that can be programmed by the developer only one time. It includes the array and logic to support read access and programming. Additionally, its pages can be write protected.

OTP enables developers to store both public and private data on-chip. In addition to storing public and private key data for applications requiring security, it also allows developers to store completely user-definable data such as customer ID, product ID, MAC address, etc. Hence generic parts can be shipped which are then programmed and protected by the developer within this non-volatile memory.

I/O Memory Space

The ADSP-BF542/4/7/8/9 processors do not define a separate I/O space. All resources are mapped through the flat 32-bit address space. On-chip I/O devices have their control registers mapped into memory-mapped registers (MMRs) at addresses near the top of the 4G byte address space. These are separated into two smaller blocks, one which contains the control MMRs for all core functions, and the other which contains the registers needed for setup and control of the on-chip peripherals outside of the core. The MMRs are accessible only in supervisor mode and appear as reserved space to on-chip peripherals.

Booting

The ADSP-BF542/4/7/8/9 processor contains a small on-chip boot kernel, which configures the appropriate peripheral for booting. If the ADSP-BF542/4/7/8/9 processor is configured to

boot from boot ROM memory space, the processor starts executing from the on-chip boot ROM. For more information, see Booting Modes on Page 19.

Event Handling

The event controller on the ADSP-BF542/4/7/8/9 processor handles all asynchronous and synchronous events to the processor. The ADSP-BF542/4/7/8/9 processor provides event handling that supports both nesting and prioritization. Nesting allows multiple event service routines to be active simultaneously. Prioritization ensures that servicing of a higher-priority event takes precedence over servicing of a lower-priority event. The controller provides support for five different types of events:

- Emulation. An emulation event causes the processor to enter emulation mode, allowing command and control of the processor via the JTAG interface.
- · Reset. This event resets the processor.
- Non-Maskable Interrupt (NMI). The NMI event can be generated by the software watchdog timer or by the NMI input signal to the processor. The NMI event is frequently used as a power-down indicator to initiate an orderly shutdown of the system.
- Exceptions. Events that occur synchronously to program flow (that is, the exception is taken before the instruction is allowed to complete). Conditions such as data alignment violations and undefined instructions cause exceptions.
- Interrupts. Events that occur asynchronously to program flow. They are caused by input pins, timers, and other peripherals, as well as by an explicit software instruction.

Each event type has an associated register to hold the return address and an associated return-from-event instruction. When an event is triggered, the state of the processor is saved on the supervisor stack.

The ADSP-BF542/4/7/8/9 processor event controller consists of two stages, the core event controller (CEC) and the system interrupt controller (SIC). The core event controller works with the system interrupt controller to prioritize and control all system events. Conceptually, interrupts from the peripherals enter into the SIC, and are then routed directly into the general-purpose interrupts of the CEC.

Core Event Controller (CEC)

The CEC supports nine general-purpose interrupts (IVG15-7), in addition to the dedicated interrupt and exception events. Of these general-purpose interrupts, the two lowest-priority interrupts (IVG15-14) are recommended to be reserved for software interrupt handlers, leaving seven prioritized interrupt inputs to support the peripherals of the ADSP-BF542/4/7/8/9 processor. Table 3 describes the inputs to the CEC, identifies their names in the event vector table (EVT), and lists their priorities.

System Interrupt Controller (SIC)

The system interrupt controller provides the mapping and routing of events from the many peripheral interrupt sources to the prioritized general-purpose interrupt inputs of the CEC.

Table 3. Core Event Controller (CEC)

| Priority | Event Class | EVT Entry |
|----------------|------------------------|-----------|
| (0 is Highest) | | |
| 0 | Emulation/Test Control | EMU |
| 1 | Reset | RST |
| 2 | Non-Maskable Interrupt | NMI |
| 3 | Exception | EVX |
| 4 | Reserved | _ |
| 5 | Hardware Error | IVHW |
| 6 | Core Timer | IVTMR |
| 7 | General Interrupt 7 | IVG7 |
| 8 | General Interrupt 8 | IVG8 |
| 9 | General Interrupt 9 | IVG9 |
| 10 | General Interrupt 10 | IVG10 |
| 11 | General Interrupt 11 | IVG11 |
| 12 | General Interrupt 12 | IVG12 |
| 13 | General Interrupt 13 | IVG13 |
| 14 | General Interrupt 14 | IVG14 |
| 15 | General Interrupt 15 | IVG15 |

Although the ADSP-BF542/4/7/8/9 processor provides a default mapping, the user can alter the mappings and priorities of interrupt events by writing the appropriate values into the interrupt assignment registers (IAR). Table 4 describes the inputs into the SIC and the default mappings into the CEC.

Table 4. System Interrupt Controller (SIC)

Event Control

The ADSP-BF542/4/7/8/9 processor provides the user with a very flexible mechanism to control the processing of events. In the CEC, three registers are used to coordinate and control events. Each register is 16 bits wide:

- CEC interrupt latch register (ILAT). The ILAT register
 indicates when events have been latched. The appropriate
 bit is set when the processor has latched the event and
 cleared when the event has been accepted into the system.
 This register is updated automatically by the controller, but
 it may be written only when its corresponding IMASK bit
 is cleared.
- CEC interrupt mask register (IMASK). The IMASK register controls the masking and unmasking of individual events. When a bit is set in the IMASK register, that event is unmasked and is processed by the CEC when asserted. A cleared bit in the IMASK register masks the event, preventing the processor from servicing the event even though the event may be latched in the ILAT register. This register may be read or written while in supervisor mode. (Note that general-purpose interrupts can be globally enabled and disabled with the STI and CLI instructions, respectively.)
- CEC interrupt pending register (IPEND). The IPEND register keeps track of all nested events. A set bit in the IPEND register indicates the event is currently active or nested at some level. This register is updated automatically by the controller but may be read while in supervisor mode.

The SIC allows further control of event processing by providing three 32-bit interrupt control and status registers. Each register contains a bit corresponding to each of the peripheral interrupt events shown in Table 4 on Page 8.

- SIC interrupt mask register (SIC_IMASK). This register
 controls the masking and unmasking of each peripheral
 interrupt event. When a bit is set in the register, that
 peripheral event is unmasked and is processed by the system when asserted. A cleared bit in the register masks the
 peripheral event, preventing the processor from servicing
 the event.
- SIC interrupt status register (SIC_ISR). As multiple peripherals can be mapped to a single event, this register allows the software to determine which peripheral event source

- triggered the interrupt. A set bit indicates the peripheral is asserting the interrupt, and a cleared bit indicates the peripheral is not asserting the event.
- SIC interrupt wakeup enable register (SIC_IWR). By
 enabling the corresponding bit in this register, a peripheral
 can be configured to wake up the processor, should the
 core be idled when the event is generated. (For more information, see Dynamic Power Management on Page 16.)

Because multiple interrupt sources can map to a single generalpurpose interrupt, multiple pulse assertions can occur simultaneously, before or during interrupt processing for an interrupt event already detected on this interrupt input. The IPEND register contents are monitored by the SIC as the interrupt acknowledgement.

The appropriate ILAT register bit is set when an interrupt rising edge is detected (detection requires two core clock cycles). The bit is cleared when the respective IPEND register bit is set. The IPEND bit indicates that the event has entered into the processor pipeline. At this point the CEC recognizes and queues the next rising edge event on the corresponding event input. The minimum latency from the rising edge transition of the general-purpose interrupt to the IPEND output asserted is three core clock cycles; however, the latency can be much higher, depending on the activity within and the state of the processor.

DMA CONTROLLERS

ADSP-BF542/4/7/8/9 processors have multiple, independent DMA channels that support automated data transfers with minimal overhead for the processor core. DMA transfers can occur between the ADSP-BF542/4/7/8/9 processor's internal memories and any of its DMA-capable peripherals. Additionally, DMA transfers can be accomplished between any of the DMA-capable peripherals and external devices connected to the external memory interfaces, including DDR and asynchronous memory controllers.

While the USB controller and MXVR have their own dedicated DMA controllers, the other on-chip peripherals are managed by two centralized DMA controllers, called DMAC1 (32-bit) and DMAC0 (16-bit). Both operate in the SCLK domain. Each DMA controller manages twelve independent peripheral DMA channels, as well as 2 independent memory DMA streams. The DMAC1 controller masters high-bandwidth peripherals over a dedicated 32-bit DMA access bus (DAB32). Similarly, the DMAC0 controller masters most of serial interfaces over the 16-bit DAB16 bus. Individual DMA channels have fixed access priority on the DAB buses. DMA priority of peripherals is managed by flexible peripheral-to-DMA channel assignment.

All four DMA controllers use the same 32-bit DCB bus to exchange data with L1 memory. This includes L1 ROM, but excludes scratchpad memory. Fine granulation of L1 memory and special DMA buffers minimize potential memory conflicts, if the L1 memory is accessed by the core contemporaneously. Similarly, there are dedicated DMA buses between the DMAC1, DMAC0, and USB DMA controllers and the external bus interface unit (EBIU) that arbitrates DMA accesses to external memories and boot ROM.

The ADSP-BF542/4/7/8/9 processor DMA controllers support both 1-dimensional (1D) and 2-dimensional (2D) DMA transfers. DMA transfer initialization can be implemented from registers or from sets of parameters called descriptor blocks.

The 2D DMA capability supports arbitrary row and column sizes up to 64K elements by 64K elements, and arbitrary row and column step sizes up to ± 32 K elements. Furthermore, the column step size can be less than the row step size, allowing implementation of interleaved data streams. This feature is especially useful in video applications where data can be deinterleaved on the fly.

Examples of DMA types supported by the ADSP-BF542/4/7/8/9 processor DMA controller include:

- A single, linear buffer that stops upon completion
- A circular, auto-refreshing buffer that interrupts on each full or fractionally full buffer
- 1-D or 2-D DMA using a linked list of descriptors
- 2-D DMA using an array of descriptors, specifying only the base DMA address within a common page

In addition to the dedicated peripheral DMA channels, both the DMAC1 and the DMAC0 controllers feature two memory DMA channel pairs for transfers between the various memories of the ADSP-BF542/4/7/8/9 processor system. This enables transfers of blocks of data between any of the memories—including external DDR, ROM, SRAM, and flash memory—with minimal processor intervention. Like peripheral DMAs, memory DMA transfers can be controlled by a very flexible descriptor-based methodology or by a standard register-based autobuffer mechanism.

The memory DMA channels of the DMAC1 controller (MDMA2 and MDMA3) can be optionally controlled by the external DMA request input pins. When used in conjunction with the External Bus Interface Unit (EBIU), this so-called Handshaked Memory DMA (HMDMA) scheme can be used to efficiently exchange data with block-buffered or FIFO-style devices connected externally. Users can select whether the DMA request pins control the source or the destination side of the memory DMA. It allows control of the number of data transfers for memory DMA. The number of transfers per edge is programmable. This feature can be programmed to allow memory DMA to have an increased priority on the external bus relative to the core.

Host DMA Port Interface

The Host DMA port (HOSTDP) facilitates a host device external to the ADSP-BF542/4/7/8/9 to be a DMA master and transfer data back and forth. The host device always masters the transactions and the processor is always a DMA slave device.

The HOSTDP port is enabled through the peripheral access bus. Once the port has been enabled, the transaction are controlled by the external host. The external host programs standard DMA

configuration words in order to send/receive data to any valid internal or external memory location. The Host DMA Port controller includes the following features:

- Allows an external master to configure DMA read/write data transfers and read port status
- Uses a flexible asynchronous memory protocol for its external interface
- Allows an 8- or 16-bit external data interface to the host device
- Supports half-duplex operation
- Supports Little/Big Endian data transfers
- Acknowledge mode allows flow control on host transactions
- Interrupt mode guarantees a burst of FIFO depth host transactions

REAL-TIME CLOCK

The ADSP-BF542/4/7/8/9 processor Real-Time Clock (RTC) provides a robust set of digital watch features, including current time, stopwatch, and alarm. The RTC is clocked by a 32.768 KHz crystal external to the ADSP-BF542/4/7/8/9 processors. The RTC peripheral has dedicated power supply pins so that it can remain powered up and clocked even when the rest of the processor is in a low-power state. The RTC provides several programmable interrupt options, including interrupt per second, minute, hour, or day clock ticks, interrupt on programmable stopwatch countdown, or interrupt at a programmed alarm time.

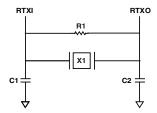

The 32.768 KHz input clock frequency is divided down to a 1 Hz signal by a prescaler. The counter function of the timer consists of four counters: a 60-second counter, a 60-minute counter, a 24-hour counter, and an 32,768-day counter.

When enabled, the alarm function generates an interrupt when the output of the timer matches the programmed value in the alarm control register. There are two alarms: The first alarm is for a time of day. The second alarm is for a day and time of that day.

The stopwatch function counts down from a programmed value, with one-second resolution. When the stopwatch is enabled and the counter underflows, an interrupt is generated.

Like the other peripherals, the RTC can wake up the ADSP-BF542/4/7/8/9 processor from sleep mode upon generation of any RTC wakeup event. Additionally, an RTC wakeup event can wake up the ADSP-BF542/4/7/8/9 processor from deep sleep mode, and wake up the on-chip internal voltage regulator from the hibernate operating mode.

Connect RTC pins RTXI and RTXO with external components as shown in Figure 4.

SUGGESTED COMPONENTS: ECLIPTEK EC38J (THROUGH-HOLE PACKAGE) EPSON MC405 12 PF LOAD (SURFACE MOUNT PACKAGE) C1 = 22 PF C2 = 22 PF R1 = 10 $M\Omega$

NOTE: C1 AND C2 ARE SPECIFIC TO CRYSTAL SPECIFIED FOR X1. CONTACT CRYSTAL MANUFACTURER FOR DETAILS. C1 AND C2 SPECIFICATIONS ASSUME BOARD TRACE CAPACITANCE OF 3 PF.

Figure 4. External Components for RTC

WATCHDOG TIMER

The ADSP-BF542/4/7/8/9 processor includes a 32-bit timer that can be used to implement a software watchdog function. A software watchdog can improve system availability by forcing the processor to a known state through generation of a hardware reset, non-maskable interrupt (NMI), or general-purpose interrupt, if the timer expires before being reset by software. The programmer initializes the count value of the timer, enables the appropriate interrupt, then enables the timer. Thereafter, the software must reload the counter before it counts to zero from the programmed value. This protects the system from remaining in an unknown state where software, which would normally reset the timer, has stopped running due to an external noise condition or software error.

If configured to generate a hardware reset, the watchdog timer resets both the core and the ADSP-BF542/4/7/8/9 processor peripherals. After a reset, software can determine if the watchdog was the source of the hardware reset by interrogating a status bit in the watchdog timer control register.

The timer is clocked by the system clock (SCLK), at a maximum frequency of f_{SCLK} .

TIMERS

There are up to two timer units in the ADSP-BF542/4/7/8/9 processors. One unit provides eight general-purpose programmable timers and the other unit provides three. Each timer has an external pin that can be configured either as a Pulse Width Modulator (PWM) or timer output, as an input to clock the timer, or as a mechanism for measuring pulse widths and periods of external events. These timers can be synchronized to an external clock input on the TMRx pins, an external clock TMRCLK input pin, or to the internal SCLK.

The timer units can be used in conjunction with the two UARTs and the CAN controller to measure the width of the pulses in the data stream to provide a software auto-baud detect function for the respective serial channels.

The timers can generate interrupts to the processor core providing periodic events for synchronization, either to the system clock or to a count of external signals.

In addition to the general-purpose programmable timers, another timer is also provided by the processor core. This extra timer is clocked by the internal processor clock and is typically used as a system tick clock for generation of operating system periodic interrupts.

UP/DOWN COUNTER AND THUMBWHEEL INTERFACE

A 32-bit up/down counter is provided that can sense 2-bit quadrature or binary codes as typically emitted by industrial drives or manual thumb wheels. The counter can also operate in general-purpose up/down count modes. Then, count direction is either controlled by a level-sensitive input pin or by two edge detectors

A third input can provide flexible zero marker support and can alternatively be used to input the push-button signal of thumb wheels. All three pins have a programmable debouncing circuit.

An internal signal forwarded to the timer unit enables one timer to measure the intervals between count events. Boundary registers enable auto-zero operation or simple system warning by interrupts when programmable count values are exceeded.

SERIAL PORTS (SPORTS)

The ADSP-BF542/4/7/8/9 processor incorporates up to four dual-channel synchronous serial ports (SPORT0, SPORT1, SPORT2, SPORT3) for serial and multiprocessor communications. The SPORTs support the following features:

- I²S capable operation.
- Bidirectional operation. Each SPORT has two sets of independent transmit and receive pins, enabling eight channels of I²S stereo audio.
- Buffered (8-deep) transmit and receive ports. Each port has a data register for transferring data words to and from other processor components and shift registers for shifting data in and out of the data registers.
- Clocking. Each transmit and receive port can either use an external serial clock or generate its own, in frequencies ranging from ($f_{SCLK}/131,070$) Hz to ($f_{SCLK}/2$) Hz.
- Word length. Each SPORT supports serial data words from 3 to 32 bits in length, transferred most-significant-bit first or least-significant-bit first.
- Framing. Each transmit and receive port can run with or
 without frame sync signals for each data word. Frame sync
 signals can be generated internally or externally, active high
 or low, and with either of two pulsewidths and early or late
 frame sync.

- Companding in hardware. Each SPORT can perform A-law or μ -law companding according to ITU recommendation G.711. Companding can be selected on the transmit and/or receive channel of the SPORT without additional latencies.
- DMA operations with single-cycle overhead. Each SPORT can automatically receive and transmit multiple buffers of memory data. The processor can link or chain sequences of DMA transfers between a SPORT and memory.
- Interrupts. Each transmit and receive port generates an interrupt upon completing the transfer of a data word or after transferring an entire data buffer or buffers through DMA.
- Multichannel capability. Each SPORT supports 128 channels out of a 1024-channel window and is compatible with the H.100, H.110, MVIP-90, and HMVIP standards.

SERIAL PERIPHERAL INTERFACE (SPI) PORTS

The ADSP-BF542/4/7/8/9 processor has up to three SPI-compatible ports that allow the processor to communicate with multiple SPI-compatible devices.

Each SPI port uses three pins for transferring data: two data pins (master output-slave input, MOSI, and master input-slave output, MISO) and a clock pin (serial clock, SCK). An SPI chip select input pin (\$\overline{SPISS}\$) lets other SPI devices select the processor, and three SPI chip select output pins per SPI port let the processor select other SPI devices. The SPI select pins are reconfigured programmable flag pins. Using these pins, the SPI ports provide a full-duplex, synchronous serial interface, which supports both master/slave modes and multimaster environments.

The SPI port's baud rate and clock phase/polarities are programmable, and it has an integrated DMA controller, configurable to support transmit or receive data streams. The SPI's DMA controller can only service unidirectional accesses at any given time.

The SPI port's clock rate is calculated as:

$$SPI Clock Rate = \frac{f_{SCLK}}{2 \times SPI_Baud}$$

Where the 16-bit SPI_BAUD register contains a value of 2 to 65.535

During transfers, the SPI port simultaneously transmits and receives by serially shifting data in and out on its two serial data lines. The serial clock line synchronizes the shifting and sampling of data on the two serial data lines.

UART PORTS (UARTS)

The ADSP-BF542/4/7/8/9 processor provides up to four full-duplex Universal Asynchronous Receiver/Transmitter (UART) ports. Each UART port provides a simplified UART interface to other peripherals or hosts, supporting full-duplex, DMA-supported, asynchronous transfers of serial data. A UART port

includes support for 5 to 8 data bits, 1 or 2 stop bits, and none, even, or odd parity. Each UART port supports two modes of operation:

- PIO (programmed I/O). The processor sends or receives data by writing or reading I/O-mapped UART registers.
 The data is double-buffered on both transmit and receive.
- DMA (Direct Memory Access). The DMA controller transfers both transmit and receive data. This reduces the number and frequency of interrupts required to transfer data to and from memory. Each UART has two dedicated DMA channels, one for transmit and one for receive. These DMA channels have lower default priority than most DMA channels because of their relatively low service rates. Flexible interrupt timing options are available on the transmit side.

Each UART port's baud rate, serial data format, error code generation and status, and interrupts are programmable:

- Supporting bit rates ranging from (f_{SCLK}/ 1,048,576) to (f_{SCLK}) bits per second.
- Supporting data formats from 7 to 12 bits per frame.
- Both transmit and receive operations can be configured to generate maskable interrupts to the processor.

The UART port's clock rate is calculated as:

$$UART\ Clock\ Rate\ =\ \frac{f_{SCLK}}{16^{(1-EDBO)}\times UART_Divisor}$$

Where the 16-bit UART Divisor comes from the UARTx_DLH register (most significant 8 bits) and UARTx_DLL register (least significant 8 bits, and EDBO is a bit in the UARTx_GCTL register).

In conjunction with the general-purpose timer functions, auto-baud detection is supported.

UART1 and UART3 feature a pair of RTS (request to send) and CTS (clear to send) signals for hardware flow purposes. The transmitter hardware is automatically prevented from sending further data when the CTS input is de-asserted. The receiver can automatically de-assert its RTS output when the enhanced receive FIFO exceeds a certain high-water level. The capabilities of the UARTs are further extended with support for the Infrared Data Association (IrDA*) Serial Infrared Physical Layer Link Specification (SIR) protocol.

CONTROLLER AREA NETWORK (CAN)

The ADSP-BF542/4/9 processor offers up to two CAN controllers that are communication controllers that implement the Controller Area Network (CAN) 2.0B (active) protocol. This protocol is an asynchronous communications protocol used in both industrial and automotive control systems. The CAN protocol is well suited for control applications due to its capability to communicate reliably over a network since the protocol incorporates CRC checking message error tracking, and fault node confinement. CAN controllers are only available on the Automotive Grade versions for ADSP-BF542 and ADSP-BF544 processors. CAN is always available on the Industrial Grade versions

sion of the ADSP-BF548 processor and the Automotive Grade version of the ADSP-BF549 processor since those only have one version each offered.

The ADSP-BF542/4/9 CAN controllers offer the following features:

- 32 mailboxes (8 receive only, 8 transmit only, 16 configurable for receive or transmit).
- Dedicated acceptance masks for each mailbox.
- Additional data filtering on first two bytes.
- Support for both the standard (11-bit) and extended (29-bit) identifier (ID) message formats.
- Support for remote frames.
- Active or passive network support.
- CAN wakeup from hibernation mode (lowest static power consumption mode).
- Interrupts, including: TX complete, RX complete, error, global.

The electrical characteristics of each network connection are very demanding so the CAN interface is typically divided into two parts: a controller and a transceiver. This allows a single controller to support different drivers and CAN networks. The ADSP-BF542/4/9 CAN module represents only the controller part of the interface. The controller interface supports connection to 3.3V high-speed, fault-tolerant, single-wire transceivers.

TWI CONTROLLER INTERFACE

The ADSP-BF542/4/7/8/9 processor includes up to two Two Wire Interface (TWI) modules for providing a simple exchange method of control data between multiple devices. The modules are compatible with the widely used I²C bus standard. The TWI modules offer the capabilities of simultaneous Master and Slave operation, support for both 7-bit addressing and multimedia data arbitration. Each TWI interface uses two pins for transferring clock (SCL) and data (SDA) and supports the protocol at speeds up to 400k bits/sec. The TWI interface pins are compatible with 5 V logic levels.

Additionally, the ADSP-BF542/4/7/8/9 processor's TWI modules are fully compatible with Serial Camera Control Bus (SCCB) functionality for easier control of various CMOS camera sensor devices.

PORTS

Because of their rich set of peripherals, the ADSP-BF542/4/7/8/9 processors group the many peripheral signals to ten ports—referred to as Port A to Port J. Most ports contain 16 pins, a few have less. Many of the associated pins are shared by multiple signals. The ports function as multiplexer controls. Every port has its own set of memory-mapped registers to control port muxing and GPIO functionality.

General-Purpose I/O (GPIO)

Every pin in Port A to Port J can function as a GPIO pin resulting in a GPIO pin count of 154. While it is unlikely that all GPIOs will be used in an application as all pins have multiple

functions, the richness of GPIO functionality guarantees unrestrictive pin usage. Every pin that is not used by any function can be configured in GPIO mode on an individual basis.

After reset, all pins are in GPIO mode by default. Neither GPIO output nor input drivers are active by default. Unused pins can be left unconnected, therefore. GPIO data and direction control registers provide flexible write-one-to-set and write-one-to-clear mechanisms so that independent software threads do not need to protect against each other because of expensive read-modify-write operations when accessing the same port.

Pin Interrupts

Due to its large number of port pins, the ADSP-BF542/4/7/8/9 processors introduce a new scheme to manage pin interrupts. Every port pin can request interrupts in either an edge-sensitive or a level-sensitive manner with programmable polarity. Interrupt functionality is decoupled from GPIO operation. Four system-level interrupt channels (INT0, INT1, INT2 and INT3) are reserved for this purpose. Each of these interrupt channels can manage up to 32 interrupt pins. The assignment from pin to interrupt is not performed at a pin by pin level. Rather, groups of eight pins (half ports) can be flexibly assigned to interrupt channels.

Every pin interrupt channel features a special set of 32-bit memory-mapped registers that enable half-port assignment and interrupt management. This not only includes masking, identification, and clearing of requests, it also enables access to the respective pin states and use of the interrupt latches regardless of whether the interrupt is masked or not. Most control registers feature multiple MMR address entries to write-one-to-set or write-one-to-clear them individually.

PIXEL COMPOSITOR (PIXC)

The pixel compositor (PIXC) provides image overlay with transparent-color support, alpha blending, and color space conversion capability for output to TFT-LCDs as well as NTSC/PAL video encoders. It provides all of the control to allow two data streams from two separate data buffers to be combined, blended, and converted into appropriate forms for both LCD panels and digital video outputs. The main image buffer provides the basic background image, which is presented in the data stream. The overlay image buffer allows the user to add multiple foreground text, graphics, or video objects on top of the main image or video data stream.

ENHANCED PARALLEL PERIPHERAL INTERFACE (EPPI)

The ADSP-BF542/4/7/8/9 processor provides up to three Enhanced Parallel Peripheral Interfaces (EPPIs), supporting data widths up to 24 bits wide. The EPPI supports direct connection to TFT LCD panels, parallel A/D and D/A converters, video encoders and decoders, image sensor modules and other general purpose peripherals.

The following features are supported in the EPPI module.

- Programmable data length: 8, 10, 12, 14, 16, 18, and 24 bits per clock.
- · Bi-directional and half-duplex port.
- Clock can be provided externally or can be generated internally.
- Various framed and non-framed operating modes. Frame syncs can be generated internally or can be supplied by an external device.
- Various general purpose modes with one frame syncs, two frame syncs, three frame syncs and zero frame sync modes for both receive and transmit directions.
- ITU-656 status word error detection and correction for ITU-656 Receive modes.
- ITU-656 preamble and status word decode.
- Three different modes for ITU-656 receive modes: active video only, vertical blanking only, and entire field mode.
- Horizontal and vertical windowing for GP 2 and 3 frame sync modes.
- Optional packing and unpacking of data to/from 32 bits from/to 8, 16 and 24 bits. If packing/unpacking is enabled, endianness can be changed to change the order of packing/unpacking of bytes/words.
- Optional sign extension or zero fill for receive modes.
- During receive modes, alternate even or odd data samples can be filtered out.
- Programmable clipping of data values for 8-bit transmit modes.
- RGB888 can be converted to RGB666 or RGB565 for transmit modes.
- Various de-interleaving/interleaving modes for receiving/transmitting 4:2:2 YCrCb data.
- FIFO watermarks and urgent DMA features.
- Clock gating by an external device asserting the clock gating control signal.
- Configurable LCD Data Enable (DEN) output available on Frame Sync 3.

USB ON-THE-GO DUAL-ROLE DEVICE CONTROLLER

The USB OTG controller provides a low-cost connectivity solution for consumer mobile devices such as cell phones, digital still cameras and MP3 players, allowing these devices to transfer data using a point-to-point USB connection without the need for a PC host. The USBDRC module can operate in a traditional USB peripheral-only mode as well as the host mode presented in the On-The-Go (OTG) supplement [1] to the USB 2.0 Specification [2]. In host mode, the USB module supports transfers at high-speed (480Mbps), full-speed (12Mbps), and low-speed (1.5Mbps) rates. Peripheral-only mode supports the high- and full-speed transfer rates.

ATA/ATAPI-6 INTERFACE

The ATAPI interface connects to CD/DVD and HDD drives, and is ATAPI-6 compliant. The controller implements the peripheral I/O mode, the multi-DMA mode, and the Ultra DMA mode. The DMA modes enable faster data transfer and reduced host management. The ATAPI Controller supports PIO, Multi-DMA, and Ultra DMA ATAPI accesses. Key features include:

- Supports PIO modes 0,1,2,3,4
- Supports Multiword DMA modes 0,1,2
- Supports Ultra DMA modes 0,1,2,3,4,5 (up to UDMA 100)
- Programmable timing for ATA interface unit
- Supports CompactFlash Card using True IDE mode

KEYPAD INTERFACE

The keypad interface is a 16-pin interface module that is used to detect the key pressed in a 8x8 (maximum) keypad matrix. The size of the input keypad matrix is programmable. The interface is capable of filtering the bounce on the input pins, which is common in keypad applications. The width of the filtered bounce is programmable. The module is capable of generating an interrupt request to the core once it identifies that any key has been pressed.

The interface supports a press-release-press mode and infrastructure for a press-hold mode. The former mode identifies a press, release and press of a key as two consecutive presses of the same key whereas the later mode checks the input key's state in periodic intervals to determine the number of times the same key is meant to be pressed. It is possible to detect when multiple keys are pressed simultaneously, and to provide limited key resolution capability when this happens.

SECURE DIGITAL (SD)/SDIO CONTROLLER

The SD/SDIO controller is a serial interface that stores data at a data rate of up to 10M bytes per second using a 4-bit data line. The interface runs at 25 MHz.

The SD/SDIO controller supports the SD memory mode only. The interface supports all the power modes and performs error checking by CRC.

CODE SECURITY

An OTP/security system consisting of a blend of hardware and software provides customers with a flexible and rich set of code security features with Lockbox $^{\text{MI}}$ secure technology. Key features include:

- OTP memory
- Unique chip ID
- Code authentication
- Secure mode of operation

¹Lockbox is a trademark of Analog Devices, Inc.

The security scheme is based upon the concept of authentication of digital signatures using standards-based algorithms and provides a secure processing environment in which to execute code and protect assets.

MEDIA TRANSCEIVER MAC LAYER (MXVR)

The ADSP-BF549 processor provides a Media Transceiver (MXVR) MAC layer, allowing the processor to be connected directly to a MOST^{®1} network through just an FOT or Electrical PHY.

The MXVR is fully compatible with the industry standard standalone MOST controller devices, supporting 22.579 Mbps or 24.576 Mbps data transfer. It offers faster lock times, greater jitter immunity, a sophisticated DMA scheme for data transfers, and the high-speed internal interface to the core and L1 memory allows the full bandwidth of the network to be utilized. The MXVR can operate as either the network master or as a network slave.

The MXVR supports synchronous data, asynchronous packets, and control messages using dedicated DMA channels which operate autonomously from the processor core moving data to and from L1 and/or L2 memory. Synchronous data is transferred to or from the synchronous data physical channels on the MOST bus through eight programmable DMA channels. The synchronous data DMA channels can operate in various modes including modes which trigger DMA operation when data patterns are detected in the receive data stream. Furthermore two DMA channels support asynchronous traffic and a further two support control message traffic.

Interrupts are generated when a user defined amount of synchronous data has been sent or received by the processor or when asynchronous packets or control messages have been sent or received.

The MXVR peripheral can wake up the ADSP-BF549 processor from sleep mode when a wakeup preamble is received over the network or based on any other MXVR interrupt event. Additionally, detection of network activity by the MXVR can be used to wake up the ADSP-BF549 processor from sleep mode or hibernate. These features allow the ADSP-BF549 to operate in a low-power state when there is no network activity or when data is not currently being received or transmitted by the MXVR.

The MXVR clock is provided through a dedicated external crystal or crystal oscillator. The frequency of external crystal or crystal oscillator can be 256Fs, 384Fs, 512Fs, or 1024Fs for Fs = 38kHz, 44.1kHz, or 48kHz. If using a crystal to provide the MXVR clock, use a parallel-resonant, fundamental mode, microprocessor-grade crystal.

DYNAMIC POWER MANAGEMENT

The ADSP-BF542/4/7/8/9 processor provides five operating modes, each with a different performance/power profile. In addition, dynamic power management provides the control functions to dynamically alter the processor core supply voltage, further reducing power dissipation. Control of clocking to each

of the ADSP-BF542/4/7/8/9 processor peripherals also reduces power consumption. See Table 5 for a summary of the power settings for each mode.

Full-On Operating Mode – Maximum Performance

In the full-on mode, the PLL is enabled and is not bypassed, providing capability for maximum operational frequency. This is the power-up default execution state in which maximum performance can be achieved. The processor core and all enabled peripherals run at full speed.

Active Operating Mode – Moderate Power Savings

In the active mode, the PLL is enabled but bypassed. Because the PLL is bypassed, the processor's core clock (CCLK) and system clock (SCLK) run at the input clock (CLKIN) frequency. In this mode, the CLKIN to CCLK multiplier ratio can be changed, although the changes are not realized until the Full-On mode is entered. DMA access is available to appropriately configured L1 memories.

In the active mode, it is possible to disable the PLL through the PLL Control register (PLL_CTL). If disabled, the PLL must be re-enabled before transitioning to the full-on or sleep modes.

Table 5. Power Settings

| Mode | PLL | PLL Bypassed | Core Clock (CCLK) | System Clock (SCLK) | Core Power |
|------------|----------------------|-----------------|-------------------------|---------------------------|---------------|
| Full On | Enabled | No | Enabled | Enabled | On |
| Active | Enabled/ Disabled | Yes | Enabled | Enabled | On |
| Sleep | Enabled | - | Disabled | Enabled | On |
| Deep Sleep | Disabled | - | Disabled | Disabled | On |
| Hibernate | Disabled | - | Disabled | Disabled | Off |

Sleep Operating Mode - High Dynamic Power Savings

The sleep mode reduces dynamic power dissipation by disabling the clock to the processor core (CCLK). The PLL and system clock (SCLK), however, continue to operate in this mode. Typically an external event or RTC activity will wake up the processor. When in the sleep mode, assertion of wakeup will cause the processor to sense the value of the BYPASS bit in the PLL control register (PLL_CTL). If BYPASS is disabled, the processor will transition to the full on mode. If BYPASS is enabled, the processor will transition to the active mode.

When in the sleep mode, system DMA access to L1 memory is not supported.

Deep Sleep Operating Mode – Maximum Dynamic Power Savings

The deep sleep mode maximizes dynamic power savings by disabling the clocks to the processor core (CCLK) and to all synchronous peripherals (SCLK). Asynchronous peripherals, such as the RTC, may still be running but will not be able to access internal resources or external memory. This powered-

 $^{^{\}rm 1}\,{\rm MOST}$ is a registered trademark of Standard Microsystems, Corp.

down mode can only be exited by assertion of the reset interrupt (\overline{RESET}) or by an asynchronous interrupt generated by the RTC. When in deep sleep mode, an RTC asynchronous interrupt causes the processor to transition to the active mode. Assertion of \overline{RESET} while in deep sleep mode causes the processor to transition to the full on mode.

Hibernate State - Maximum Static Power Savings

The hibernate state maximizes static power savings by disabling the voltage and clocks to the processor core (CCLK) and to all the synchronous peripherals (SCLK). The internal voltage regulator for the processor can be shut off by writing b#00 to the FREQ bits of the VR_CTL register. This disables both CCLK and SCLK. Furthermore, it sets the internal power supply voltage (V $_{\rm DDINT}$) to 0V to provide the greatest power savings mode. Any critical information stored internally (memory contents, register contents, etc.) must be written to a non-volatile storage device prior to removing power if the processor state is to be preserved.

Since $V_{\rm DDEXT}$ is still supplied in this mode, all of the external pins tri-state, unless otherwise specified. This allows other devices that may be connected to the processor to have power still applied without drawing unwanted current.

The internal supply regulator can be woken up by CAN, by the MXVR, by the keypad, by the up/down counter, by the USB, and by some GPIO pins. It can also be woken up by a real-time clock wakeup event or by asserting the RESET pin. Waking up from hibernate state initiates the hardware reset sequence.

With the exception of the VR_CTL and the RTC registers, all internal registers and memories lose their content in hibernate state. State variables may be held in external SRAM or SDRAM.

Power Savings

As shown in Table 6, the ADSP-BF542/4/7/8/9 processor supports different power domains. The use of multiple power domains maximizes flexibility, while maintaining compliance with industry standards and conventions. By isolating the internal logic of the ADSP-BF542/4/7/8/9 processor into its own power domain, separate from the RTC and other I/O, the processor can take advantage of dynamic power management, without affecting the RTC or other I/O devices. There are no sequencing requirements for the various power domains.

Table 6. Power Domains

| Power Domain | VDD Range |
|--|-------------------|
| All internal logic, except RTC, DDR, and USB | V_{DDINT} |
| RTC internal logic and crystal I/O | V_{DDRTC} |
| DDR external memory supply | V_{DDDDR} |
| USB internal logic and crystal I/O | V_{DDUSB} |
| Internal voltage regulator | V_{DDVR} |
| MXVR PLL and logic | V_{DDMP} |
| All other I/O | V_{DDEXT} |

VOLTAGE REGULATION

The ADSP-BF542/4/7/8/9 processor provides an on-chip voltage regulator that can generate processor core voltage levels from an external supply. (Note specifications as indicated in Operating Conditions on Page 32.) Figure 5 shows the typical external components required to complete the power management system. The regulator controls the internal logic voltage levels and is programmable with the voltage regulator control register (VR_CTL) in increments of 50 mV. To reduce standby power consumption, the internal voltage regulator can be programmed to remove power to the processor core while keeping I/O power supplied. While in hibernate mode, V_{DDEXT}, V_{DDRTC}, V_{DDDDR}, V_{DDUSB}, and V_{DDVR} can still be applied, eliminating the need for external buffers. The voltage regulator can be activated from this power down state by assertion of the RESET pin, which will then initiate a boot sequence. The regulator can also be disabled and bypassed at the user's discretion. For additional information, see "Switching Regulator Design Considerations for the ASDP-BF533 Blackfin Processors" (EE-228).

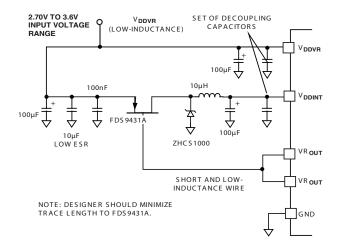

Figure 5. Voltage Regulator Circuit

CLOCK SIGNALS

The ADSP-BF542/4/7/8/9 processor can be clocked by an external crystal, a sine wave input, or a buffered, shaped clock derived from an external clock oscillator.

If an external clock is used, it should be a TTL compatible signal and must not be halted, changed, or operated below the specified frequency during normal operation. This signal is connected to the processor's CLKIN pin. When an external clock is used, the XTAL pin must be left unconnected.

Alternatively, because the ADSP-BF542/4/7/8/9 processor includes an on-chip oscillator circuit, an external crystal may be used. For fundamental frequency operation, use the circuit

shown in Figure 6. A parallel-resonant, fundamental frequency, microprocessor-grade crystal is connected across the CLKIN and XTAL pins. The on-chip resistance between CLKIN and the XTAL pin is in the 500 k Ω range. Further parallel resistors are typically not recommended. The two capacitors and the series resistor shown in Figure 6 fine tune phase and amplitude of the sine frequency.

The capacitor and resistor values shown in Figure 6 are typical values only. The capacitor values are dependent upon the crystal manufacturers' load capacitance recommendations and the PCB physical layout. The resistor value depends on the drive level specified by the crystal manufacturer. System designs should verify the customized values based on careful investigations on multiple devices over temperature range.

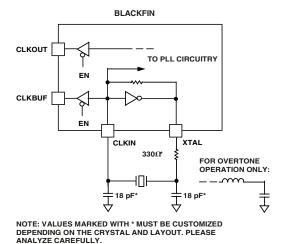

Figure 6. External Crystal Connections

A third-overtone crystal can be used at frequencies above 25 MHz. The circuit is then modified to ensure crystal operation only at the third overtone, by adding a tuned inductor circuit as shown in Figure 6. A design procedure for third-overtone operation is discussed in detail in application note EE-168.

The Blackfin core runs at a different clock rate than the on-chip peripherals. As shown in Figure 7 on Page 18, the core clock (CCLK) and system peripheral clock (SCLK) are derived from the input clock (CLKIN) signal. An on-chip PLL is capable of multiplying the CLKIN signal by a programmable 0.5× to 64× multiplication factor (bounded by specified minimum and maximum VCO frequencies). The default multiplier is 8×, but it can be modified by a software instruction sequence. On-the-fly frequency changes can be effected by simply writing to the PLL_DIV register.

On-the-fly CCLK and SCLK frequency changes can be effected by simply writing to the PLL_DIV register. Whereas the maximum allowed CCLK and SCLK rates depend on the applied voltages $V_{\rm DDINT}$ and $V_{\rm DDEXT}$, the VCO is always permitted to run up to the frequency specified by the part's speed grade. The CLKOUT pin reflects the SCLK frequency to the off-chip world. It functions as reference for many timing specifications. While inactive by default, it can be enabled using the EBIU_SDGCTL and EBIU_AMGCTL registers.

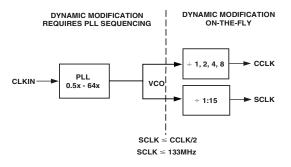

Figure 7. Frequency Modification Methods

All on-chip peripherals are clocked by the system clock (SCLK). The system clock frequency is programmable by means of the SSEL3–0 bits of the PLL_DIV register. The values programmed into the SSEL fields define a divide ratio between the PLL output (VCO) and the system clock. SCLK divider values are two through 15. Table 7 illustrates typical system clock ratios. The default ratio is 4.

Table 7. Example System Clock Ratios

| Signal Name | Divider Ratio | Example Frequency Ratios (MHz) | |
|-------------|---------------|--------------------------------|------|
| SSEL3-0 | VCO/SCLK | vco | SCLK |
| 0010 | 2:1 | 200 | 100 |
| 0110 | 6:1 | 300 | 50 |
| 1010 | 10:1 | 500 | 50 |

Note that the divisor ratio must be chosen to limit the system clock frequency to its maximum of f_{SCLK} . The SSEL value can be changed dynamically without any PLL lock latencies by writing the appropriate values to the PLL divisor register (PLL_DIV).

The core clock (CCLK) frequency can also be dynamically changed by means of the CSEL1–0 bits of the PLL_DIV register. Supported CCLK divider ratios are 1, 2, 4, and 8, as shown in Table 8. The default ratio is 1. This programmable core clock capability is useful for fast core frequency modifications.

The maximum CCLK frequency not only depends on the part's speed grade, it also depends on the applied $V_{\rm DDINT}$ voltage. See Table 16 through Table 18 for details.

Table 8. Core Clock Ratios

| Signal Name CSEL1-0 | Divider Ratio VCO/CCLK | Example Frequency Ratios (MHz) | | |
|------------------------|---------------------------|--------------------------------|------|--|
| | | vco | CCLK | |
| 00 | 1:1 | 300 | 300 | |
| 01 | 2:1 | 300 | 150 | |
| 10 | 4:1 | 500 | 125 | |
| 11 | 8:1 | 200 | 25 | |

BOOTING MODES

The ADSP-BF542/4/7/8/9 processor has many mechanisms (listed in Table 9) for automatically loading internal and external memory after a reset. The boot mode is defined by four BMODE input pins dedicated to this purpose. There are two categories of boot modes: In master boot modes the processor actively loads data from parallel or serial memories. In slave boot modes the processor receives data from an external host devices.

Table 9. Booting Modes

| BMODE3-0 | Description |
|----------|--|
| 0000 | Idle-no boot |
| 0001 | Boot from 8- or 16-bit external flash memory |
| 0010 | Boot from 16-bit asynchronous FIFO |
| 0011 | Boot from serial SPI memory (EEPROM or flash) |
| 0100 | Boot from SPI host device |
| 0101 | Boot from serial TWI memory (EEPROM/flash) |
| 0110 | Boot from TWI host |
| 0111 | Boot from UART host |
| 1000 | Reserved |
| 1001 | Reserved |
| 1010 | Boot from (DDR) SDRAM |
| 1011 | Boot from OTP memory |
| 1100 | Reserved |
| 1101 | Boot from 8- or 16-bit NAND flash memory via NFC |
| 1110 | Boot from 16-Bit Host DMA |
| 1111 | Boot from 8-Bit Host DMA |

The boot modes listed in Table 9 provide a number of mechanisms for automatically loading the processor's internal and external memories after a reset. By default all boot modes use the slowest meaningful configuration settings. Default settings can be altered via the initialization code feature at boot time or by proper OTP programming at pre-boot time. The BMODE

pins of the reset configuration register, sampled during poweron resets and software-initiated resets, implement the following modes:

- Idle-no boot mode (BMODE=0x0) In this mode, the processor goes into idle. The idle boot mode helps to recover from illegal operating modes, in the case the user misconfigured the OTP memory.
- Boot from 8- or 16-bit external flash memory (BMODE=0x1) In this mode, the boot kernel loads the first block header from address 0x2000 0000 and—depending on instructions containing in the header—the boot kernel performs 8-bit or 16-bit boot or starts program execution at the address provided by the header. By default, all configuration settings are set for the slowest device possible (3-cycle hold time; 15-cycle R/W access times; 4-cycle setup).
 - The ARDY is not enabled by default. It can however, be enabled by OTP programming. Similarly, all interface behavior and timings can customized up by OTP programming. This includes activation of burst-mode or pagemode operation. In this mode, all signals belonging to the asynchronous interface are enabled at port muxing level.
- Boot from 16-bit asynchronous FIFO (BMODE=0x2) In this mode, the boot kernel starts booting from address 0x2030 0000. Every 16-bit word that boot kernel has to read from the FIFO must be requested by an low pulse on the DMAR1 pin.
- Boot from serial SPI memory, EEPROM or flash (BMODE=0x3) Eight-, 16-, 24- or 32-bit addressable devices are supported. (internal note: no special support for DataFlashes, as they understand now also standard SPI protocol). The processor uses the PE4 GPIO pin to select a single SPI EEPROM/flash device, submits a read command and successive address bytes (0x00) until a valid 8-, 16-, 24-, or 32-bit addressable device is detected. Pull-up resistors are required on the SSEL and MISO pins. By default, a value of 0x85 is written to the SPI_BAUD register.
- Boot from SPI host device (BMODE=0x4) The processor operates in SPI slave mode (using SPI0) and is configured to receive the bytes of the LDR file from an SPI host (master) agent. In the host, the HWAIT signal must be interrogated by the host before every transmitted byte. A pull-up resistor is required on the SPISS input. A pull-down on the serial clock may improve signal quality and booting robustness.
- Boot from serial TWI memory, EEPROM/flash (BMODE=0x5) The processor operates in master mode (using TWI0) and selects the TWI slave with the unique id 0xA0. The processor submits successive read commands to the memory device starting at two byte internal address 0x0000 and begins clocking data into the processor. The TWI memory device should comply with Philips I²C Bus Specification version 2.1 and have the capability to autoincrement its internal address counter such that the contents of the memory device can be read sequentially. By default, a prescale value of 0xA and CLKDIV value of

Preliminary Technical Data

0x0811 is used. Unless, altered by OTP settings an I²C memory that takes two address bytes is assumed. Development tools ensure that data that is booted to memories that cannot be accessed by the Blackfin core is written to intermediate storage place and then copied to final destination via Memory DMA.

- Boot from TWI host (BMODE=0x6) The TWI host agent selects the slave with the unique id 0x5F. The processor (using TWI0) replies with an acknowledgement and the host can then download the boot stream. The TWI host agent should comply with Philips I²C Bus Specification version 2.1. An I²C multiplexer can be used to select one processor at a time when booting multiple processors from a single TWI.
- Boot from UART host (BMODE=0x7) In this mode, the
 processor uses UART1 as booting source. Using an autobaud handshake sequence, a boot-stream-formatted
 program is downloaded by the host. The host agent selects
 a bit rate within the UART's clocking capabilities.
 - When performing the autobaud, the UART expects a "@" (0x40) character (eight bits data, one start bit, one stop bit, no parity bit) on the RXD pin to determine the bit rate. It then replies with an acknowledgement which is composed of 4 bytes: 0xBF, the value of UART_DLL, the value of UART_DLH, 0x00. The host can then download the boot stream. The processor deasserts the RTS output to hold off the host; CTS functionality is not enabled at boot time.
- Boot from (DDR) SDRAM (BMODE=0xA) In this mode, the boot kernel starts booting from address 0x0000 0010. This is a warm boot scenario only. The SDRAM is expected to contain a valid boot stream and the SDRAM controller must have been configured by the OTP settings.
- Boot from 8-bit and 16-bit external NAND flash memory (BMODE=0xD) In this mode, auto detection of the NAND flash device is performed. The processor configures PORTJ GPIO pins PJ1 and PJ2 to enable the NAND CE and NAND RB signals respectively. For correct device operation pull-up resistors are required on both CE (PJ1) and RB (PJ2) signals. By default a value of 0x0033 is written to the NFC_CTL register. The booting procedure always starts by booting from byte 0 of block 0 of the NAND flash device.

NAND flash boot supports the following features:

- Device Auto Detection.
- Error Detection & Correction for maximum reliability.
- No boot stream size limitation.
- Peripheral DMA via channel 22 providing efficient transfer of all data (excluding the ECC parity data).
- Software configurable boot mode for booting from boot streams expanding multiple blocks including bad blocks.
- Software configurable boot mode for booting from multiple copies of the boot stream allowing for handling of bad blocks and uncorrectable errors.
- Configurable timing via OTP memory.

Small page NAND flash devices must have a 512 byte page size, 32 pages per block, a 16 byte spare area size and a bus configuration of 8 bits. By default all read requests from the NAND flash are followed by 4 address cycles. If the NAND flash device requires only 3 address cycles the device must be capable of ignoring the additional address cycles.

The small page NAND flash device must comply with the following command set:

Reset: 0xFF

Read lower half of page: 0x00 Read upper half of page: 0x01

Read spare area: 0x50

For large page NAND flash devices the 4 byte electronic signature is read in order to configure the kernel for booting, this allows support for multiple large page devices. Byte 4 of the electronic signature must comply with the following specification in Table 10 on page 21.

Any configuration from Table 10 that also complies with the command set listed below is directly supported by the boot kernel. There are no restrictions on the page size or block size as imposed by the small page boot kernel.

Large page devices must support the following command set:

Reset: 0xFF

Read Electronic Signature: 0x90

Read: 0x00, 0x30 (confirm command)

Large page devices must not support or react to NAND flash command 0x50. This is a small page NAND flash command used for device auto detection.

By default the boot kernel will always issue 5 address cycles, therefore if a large page device requires only 4 cycles, the device must be capable of ignoring the additional address cycles.

16-bit NAND flash memory devices must only support the issuing of command and address cycles via the lower 8 bits of the data bus. Devices that make use of the full 16-bit bus for command and address cycles are not supported.

Table 10. Byte 4 Electronic Signature Specification

| Page Size (excluding | D1.D0 | 00 | 1KBytes |
|----------------------------|--------|----|-----------------------|
| spare area) | 01.00 | 00 | TRDytes |
| spare area, | | 01 | 2KBytes |
| | | 10 | 4KBytes |
| | | 11 | 8KBytes |
| Spare Area Size | D2 | 0 | 8Bytes / 512Bytes |
| | | 1 | 16Bytes / 512Bytes |
| Block Size (excluding | D5:4 | 00 | 64KBytes |
| spare area) | | 01 | 128 kBytes |
| | | 10 | 256KBytes |
| | | 11 | 512KBytes |
| Bus width | D6 | 0 | x8 |
| | | 1 | x16 |
| Not Used for configuration | D3, D7 | | |

- Boot from OTP memory (BMODE=0xB) This provides a stand-alone booting method. The boot stream is loaded from on-chip OTP memory. By default the boot stream is expected to start from OTP page 0x40 on and can occupy all public OTP memory up to page 0xDF. This is 2560 bytes. Since the start page is programmable the maximum size of the boot stream can be extended to 3072 bytes.
- Boot from 16-Bit Host DMA (BMODE=0xE) In this mode, the host DMA port is configured in 16-bit Acknowledge mode, little endian. Unlike in other modes, here the host is responsible for interpreting the boot stream. It writes data block per data block into the Host DMA port. Before configuring the DMA settings for each block, the host may either poll the ALLOW_CONFIG bit in HOST_STATUS or wait to be interrupted by the HWAIT signal. When using HWAIT, the host must still check ALLOW_CONFIG at least once before beginning to configure the Host DMA Port. After completing the configuration the host is required to poll the READY bit in HOST_STATUS before beginning to transfer data. When the host sends an HIRQ control command, the boot kernel issues a CALL instruction to 0xFFA0 0000 address. It is the host's responsibility to ensure valid code has been placed at this address. The routine at 0xFFA0 0000 can be a simple initialization routine to configure internal resources, such

- as the SDRAM controller, then returns using an RTS instruction. The routine may also by the final application which will never return to the boot kernel.
- Boot from 8-Bit Host DMA (BMODE=0xF) In this mode, the Host DMA port is configured in 8-bit interrupt mode, little endian. Unlike in other modes, here the host is responsible for interpreting the boot stream. It writes data block per data block into the Host DMA port. Before configuring the DMA settings for each block, the host may either poll the ALLOW_CONFIG bit in HOST_STATUS or wait to be interrupted by the HWAIT signal. When using HWAIT, the host must still check ALLOW_CONFIG at least once before beginning to configure the Host DMA Port. The host will receive an interrupt from the HOST_ACK signal every time it is allowed to send the next FIFO depth (Sixteen 32-bit words) of information. When the host sends an HIRQ control command, the boot kernel issues a CALL instruction to address 0xFFA0 0000. It is the host's responsibility to ensure valid code has been place at this address. The routine at 0xFFA0 0000 can be a simple initialization routine to configure internal resources, such as the SDRAM controller, then returns using an RTS instruction. The routine may also by the final application which will never return to the boot kernel.

For each of the boot modes, a 16-byte header is first read from an external memory device. The header specifies the number of bytes to be transferred and the memory destination address. Multiple memory blocks may be loaded by any boot sequence. Once all blocks are loaded, program execution commences from the address stored in the EVT1 register.

Prior to booting, the pre-boot routine interrogates the OTP memory. Individual boot modes can be customized or even disabled based on OTP programming. External hardware, especially booting hosts may watch the HWAIT signal to determine when the pre-boot has finished and the boot kernel starts the boot process. By programming OTP memory, the user can instruct the preboot routine to also customize: PLL and Voltage Regulator; DDR Controller; and Asynchronous Interface.

The boot kernel differentiates between a regular hardware reset and a wakeup-from-hibernate event to speed up booting in the later case. Bits 6-4 in the system reset configuration (SYSCR) register can be used to bypass pre-boot routine and/or boot kernel in case of a software reset. They can also be used to simulate a wakeup-from-hibernate boot in the software reset case.

The boot process can be further customized by "initialization code." This is a piece of code that is loaded and executed prior to the regular application boot. Typically, this is used to configure the DDR controller or to speed up booting by managing PLL, clock frequencies, wait states, or serial bit rates.

The boot ROM also features C-callable function entries that can be called by the user application at run time. This enables second-stage boot or boot management schemes to be implemented with ease.

INSTRUCTION SET DESCRIPTION

The Blackfin processor family assembly language instruction set employs an algebraic syntax designed for ease of coding and readability. The instructions have been specifically tuned to provide a flexible, densely encoded instruction set that compiles to a very small final memory size. The instruction set also provides fully featured multifunction instructions that allow the programmer to use many of the processor core resources in a single instruction. Coupled with many features more often seen on microcontrollers, this instruction set is very efficient when compiling C and C++ source code. In addition, the architecture supports both user (algorithm/application code) and supervisor (O/S kernel, device drivers, debuggers, ISRs) modes of operation, allowing multiple levels of access to core processor resources.

The assembly language, which takes advantage of the processor's unique architecture, offers the following advantages:

- Seamlessly integrated DSP/MCU features are optimized for both 8-bit and 16-bit operations.
- A multi-issue load/store modified-Harvard architecture, which supports two 16-bit MAC or four 8-bit ALU + two load/store + two pointer updates per cycle.
- All registers, I/O, and memory are mapped into a unified 4G byte memory space, providing a simplified programming model.
- Microcontroller features, such as arbitrary bit and bit-field manipulation, insertion, and extraction; integer operations on 8-, 16-, and 32-bit data-types; and separate user and supervisor stack pointers.
- Code density enhancements, which include intermixing of 16- and 32-bit instructions (no mode switching, no code segregation). Frequently used instructions are encoded in 16 bits.

DEVELOPMENT TOOLS

The ADSP-BF542/4/7/8/9 processor is supported with a complete set of CROSSCORE* software and hardware development tools, including Analog Devices emulators and VisualDSP++* development environment. The same emulator hardware that supports other Blackfin processors also fully emulates the ADSP-BF542/4/7/8/9 processor.

EZ-KIT Lite® Evaluation Board

For evaluation of ADSP-BF542/4/7/8/9 processors, use the ADSP-BF548 EZ-KIT Lite board available from Analog Devices. Order part number ADDS-BF548-EZLITE. The board comes with on-chip emulation capabilities and is equipped to enable software development. Multiple daughter cards are available.

DESIGNING AN EMULATOR-COMPATIBLE PROCESSOR BOARD (TARGET)

The Analog Devices family of emulators are tools that every system developer needs to test and debug hardware and software systems. Analog Devices has supplied an IEEE 1149.1 JTAG Test Access Port (TAP) on each JTAG processor. The emulator uses the TAP to access the internal features of the processor,

allowing the developer to load code, set breakpoints, observe variables, observe memory, and examine registers. The processor must be halted to send data and commands, but once an operation has been completed by the emulator, the processor system is set running at full speed with no impact on system timing.

To use these emulators, the target board must include a header that connects the processor's JTAG port to the emulator.

For details on target board design issues including mechanical layout, single processor connections, multiprocessor scan chains, signal buffering, signal termination, and emulator pod logic, see *Analog Devices JTAG Emulation Technical Reference* (EE-68) on the Analog Devices web site under www.analog.com/ee-notes. This document is updated regularly to keep pace with improvements to emulator support.

RELATED DOCUMENTS

PIN DESCRIPTIONS

ADSP-BF542/4/7/8/9 processor pin multiplexing scheme is listed in Table 11 and the pin definitions are listed in Table 12.

Table 11. Pin Multiplexing

| Primary Pin Function (Number of Pins) ¹ , ² | First Peripheral Function | Second Peripheral Function | Third Peripheral Function | Fourth Peripheral Function | Interrupt Capability |
|--|---|---------------------------------------|------------------------------|---------------------------------------|----------------------------------|
| Port A | | | | | |
| GPIO (16 pins) | SPORT2 (8 pins) | TMR4 (1 pin) | TACI7 (1 shared pin) | | Interrupts (16 pins) |
| | | TMR5 (1 pin) | TACLK7-0 (8 pins) | | |

| | | | | | Interrupts (6 pins) |

¹ Port connections may be inputs or outputs after power up depending on BF54x family member number and boot mode chosen.

ADSP-BF542/4/7/8/9 processor pin definitions are listed in Table 12. To see the pin multiplexing scheme, see Table 11.

² All Port connections always power up as inputs for some period of time and require resistive termination to a safe condition if used as outputs in the system.

³ A total of 32 interrupts at once are available from Ports C through J, configurable in byte-wide blocks.

ADSP-BF542/4/7/8/9

Table 12. Pin Descriptions

Table 12. Pin Descriptions (Continued)

| Pin Name | I/O ¹ | Function (First/Second/Third/Fourth) |
|--|------------------|---|
| Memory Interface (Continued) | | |
| DDR_VREF | 1 | DDR Voltage Reference |
| DDR_VSSR | I | DDR Voltage Reference Shield (connect to GND) |
| Asynchronous Memory Interface | | |
| A1-3 | 0 | Address Bus for Async and ATAPI Addresses |
| D0-15/ND_D0-15/ATAPI_D0-15 | I/O | Data Bus for Async, NAND and ATAPI Accesses |
| AMS0-3 | 0 | Bank Selects |
| ABEO / ND_CLE | 0 | Byte Enables: Data Masks for Asynchronous Access/NAND Command Latch Enable |
| ABE1/ND_ALE | 0 | Byte Enables: Data Masks for Asynchronous Access/NAND Address Latch Enable |
| AOE/NR_ADV | 0 | Output Enable / NOR Address Data Valid |
| ĀRĒ | 0 | Read Enable/NOR Output Enable |
| AWE | 0 | Write Enable |
| ATAPI Controller Pins | | |
| ATAPI_PDIAG | 1 | |
| High Speed USB OTG Pins ⁹ | | |
| USB_DP | I/O | USB D+ pin |
| USB_DM | | USB D- pin |
| USB_XI | С | Clock XTAL input |
| USB_XO | С | Clock XTAL output |
| USB_ID ¹⁰ | 1 | USB ID pin |
| USB_VBUS | I/O | USB VBUS pin |
| USB_VREF | Α | USB voltage reference. Connect 0.1 μF capacitor between USB_VREF and GND. |
| USB_RSET | Α | USB resistance set. Preliminary designs should connect USB_RSET to an unpopu- |
| | | lated resistor pad. Connect the other terminal of the unpopulated resistor to GND |

Table 12. Pin Descriptions (Continued)

| Pin Name | I/O ¹ | Function (First/Second/Third/Fourth) |
|-------------------------------------|------------------|---|
| Clock (PLL) Pins | <u>.</u> | |
| CLKIN | С | Clock/Crystal Input |
| CLKOUT | 0 | Clock Output |
| XTAL | С | Crystal Output |
| CLKBUF | 0 | Buffered Oscillator output |
| EXT_WAKE | 0 | External Wakeup from hibernate output |
| RESET | 1 | Reset |
| NMI ¹⁴ | 1 | Non-maskable Interrupt |
| Supplies | | |
| V_{DDINT} | Р | Internal Power Supply |
| V _{DDEXT} 15 | Р | External Power Supply |
| V_{DDDDR} | Р | External DDR Power Supply |
| V_{DDUSB}^{15} | Р | External USB Power Supply |
| V_{DDRTC} | Р | RTC Clock Supply |
| $V_{DDVR}^{}16}$ | Р | Internal Voltage Regulator Power Supply |
| GND | G | Ground |
| $V_{\rm DDMP}^{15}$ | Р | MXVR PLL Power Supply |
| GND _{MP} ^{17, 18} | G | MXVR PLL Ground |

¹ I = Input, O = Output, P = Power, G = Ground, C = Crystal, A = Analog.

² To use the SPI memory boot, SCLK0 should have a pulldown, MISO should have a pullup, and SPISEL1 is used as CS with a pullup.

³ To use the serial TWI memory boot, SDA0 and SCL0 should have a pullup.

⁴ By default the ATAPI bus shares the data pins D0-15 and the address pins A0-2 with the asynchronous memory interface and the NAND controller. When PORTF_MUX[1:0] = b#01, then the ATAPI data bus is available through Port F and the address line can be found at Port G.

⁵The Boot Host Wait (HWAIT) signal on PB11 is a GPIO output that is driven and toggled by the boot kernel at boot time. An external pulling resistor is required for proper operation. A pull-up resistor instructs the HWAIT signal to behave active high (low when ready for data). A pull-down resistor instructs the HWAIT signal to behave active low (high when ready for data). After boot it can be used for other purposes. If the PB11 pin is required for other purposes (for example, timer or SPI operation) the Alternate Boot Host Wait (HWAITA) on PH7 can be used instead. This is enabled by programming the OTP_ALTERNATE_HWAIT bit in the PBS00L OTP memory page.

⁶This pin should not be used as GPIO if booting in mode 1.

 $^{^{7}}$ This pin should always be enabled as ND_CE in software and pulled HIGH with a resistor when using NAND flash.

⁸ This pin should always be enabled as bus request in software and pulled HIGH to enable the Async access.

⁹ For the ADSP-BF542/4/7/8/9, the unused USB pins should be terminated as follows: USB_DP --> GND; USB_DM --> GND; USB_XTALIN --> GND; USB_XTALOUT --> NC (No Connect); USB_ID --> VSS; USB_VREF --> NC; USB_RSET --> NC; USB_VBUS --> VSD; VDDUSB --> VDDEXT

 $^{^{10}}$ In the case that USB is used in device mode only, the USB_ID pin should be either pulled HIGH or left unconnected.

¹¹This pin should always be pulled either HIGH or LOW, but must not be left floating.

 $^{^{12}}$ This pin should be pulled LOW if the JTAG port will not be used.

 $^{^{13}}$ Always connect VR_{OUT}0 and VR_{OUT}1 together to reduce signal impedance.

¹⁴This pin should always be pulled HIGH when not used.

¹⁵Power and ground pins of peripherals should be driven to their specified level even if the associated peripheral is not used in the application.

¹⁶The VDDVR pin must always be connected. If the internal voltage regulator is not being used, this pin may be connected to VDDEXT. Otherwise it should be powered according to the VDDVR specification.

¹⁷Analog ground for MXVR.

¹⁸Connect to GND when MXVR is not used.

SPECIFICATIONS

Note that component specifications are subject to change without notice.

OPERATING CONDITIONS

| Parameter ¹ | | Minimum | Nominal | Maximum | Unit |
|---------------------------------|---|----------------------------|---------------------------|----------------------------|------|
| V _{DDINT} ² | Internal Supply Voltage | 0.9 | | 1.43 | ٧ |
| | Internal Supply Voltage for Automotive Grade | 1.0 | | 1.38 | V |
| $V_{\text{DDEXT}}^{3,4}$ | External Supply Voltage for 3.3V I/O | 2.7 | 3.3 | 3.6 | V |
| | External Supply Voltage for 2.5V I/O ⁷ | 2.25 | 2.5 | 2.75 | ٧ |
| | External Supply Voltage for Automotive Grade | 2.7 | 3.3 | 3.6 | V |
| V_{DDUSB}^{4} | USB External Supply Voltage | 3.0 | 3.3 | 3.6 | V |
| V_{DDMP}^{5} | MXVR PLL Supply Voltage | 0.9 | | 1.43 | ٧ |
| | MXVR PLL Supply Voltage for Automotive Grade | 1.0 | | 1.38 | ٧ |
| V_{DDRTC}^{4} | Real Time Clock Power Supply Voltage | 2.25 | | 3.6 | ٧ |
| | Real Time Clock Power Supply Voltage for Automotive Grade | 2.7 | 3.3 | 3.6 | ٧ |
| V_{DDDDR}^{4} | DDR Memory Supply Voltage | 2.3 | 2.5 | 2.7 | ٧ |
| | DDR Memory Supply Voltage for Mobile DDR | 1.7 | 1.8 | 1.9 | ٧ |
| V_{DDVR}^{6} | Internal Voltage Regulator Supply Voltage | 2.7 | 3.3 | 3.6 | ٧ |
| V_{IH} | High Level Input Voltage for 3.3V I/O ^{7,8} @ V _{DDEXT} =maximum | 2.0 | | 3.6 | ٧ |
| | High Level Input Voltage for 2.5V I/O ^{7,8} @ V _{DDEXT} =maximum | TBD | | 3.6 | ٧ |
| V_{IHCLKIN} | High Level Input Voltage for 3.3V I/O ⁹ @ V _{DDEXT} = maximum | 2.2 | | 3.6 | ٧ |
| | High Level Input Voltage for 2.5V I/O ⁹ @ V _{DDEXT} = maximum | TBD | | 3.6 | ٧ |
| V_{IHDDR} | High Level Input Voltage ¹⁰ | V _{REFDDR} + 0.15 | | $V_{DDDDR} + 0.3$ | ٧ |
| | High Level Input Voltage for Mobile DDR ¹⁰ | $0.8 \times V_{DDDDR}$ | | $V_{DDDDR} + 0.3$ | ٧ |
| V_{IH5V} | High Level Input Voltage for 3.3V I/O ¹¹ , @ V _{DDEXT} =maximum | 2.0 | | 5.5 | ٧ |
| | High Level Input Voltage for 2.5V I/O ¹¹ , @ V _{DDEXT} =maximum | TBD | | 5.5 | ٧ |
| V_{IHUSB} | High Level Input Voltage for USB_DP, USB_DM, and USB_VBUS ¹² | | | 5.5 | ٧ |
| V_{IL} | Low Level Input Voltage for 3.3V I/O ^{7, 13} , @ V _{DDEXT} =minimum | -0.3 | | 0.6 | ٧ |
| | Low Level Input Voltage for 2.5V I/O ^{7, 13} @ V _{DDEXT} =minimum | -0.3 | | TBD | ٧ |
| V_{IL5V} | Low Level Input Voltage for 3.3V I/O ¹⁴ , @ V _{DDEXT} =minimum | -0.3 | | 0.8 | V |

| T_{J}^{15} | Junction Temperature @T _{AMBIENT} = -40°C to +85°C | -40 | | +105 | ۰C |
| T_{J}^{15} | Junction Temperature @T _{AMBIENT} = 0°C to +70°C | 0 | | +90 | ۰C |

¹ Specifications subject to change without notice.

² VDDINT maximum is 1.10 V during One-Time-Programmable (OTP) memory programming operations. VDDINT maximum is per the operating conditions table for OTP memory read operations.

 $^{^3}$ VDDEXT is 3.0 V min and 3.6 V max during OTP memory programming operations. VDDEXT is specified per the operating conditions table for OTP memory read operations.

⁴ Must remain powered (even if associated function not used).

⁵Connect to VDDINT if MXVR is not used.

⁶ VDDVR must always be connected. If the internal voltage regulator is not being used, this pin may be connected to VDDEXT. Otherwise it should be powered according to this specification.

 $^{^7}$ The ADSP-BF542/4/7/8/9 processor is 3.3 V tolerant (always accepts up to 3.6 V maximum V_{IH}), but voltage compliance (on outputs, V_{OH}) depends on the input V_{DDEXT} , because V_{OH} (maximum) approximately equals V_{DDEXT} (maximum). This 3.3 V tolerance applies to bi-directional pins (D15–0, PA15–0, PB14–0, PC15–0, PD15–0, PE15–0, PF15–0, PG15–0, PH13–0, PI15–0, PJ14–0) and input only pins (ATAPI_PDIAG, USB_ID, TCK, TDI, TMS, TRST, CLKIN, TEST, NMI, and BMODE3–0).

⁸ Parameter value applies to all input and bi-directional pins, except CLKIN, PB0, PB1, PE14, PE15, PG15–11, PH6, PH7, and the pins listed in table note 10 of the Operating Conditions table.

ADSP-BF542/4/7/8/9

⁹ Parameter value applies to CLKIN pin only.

¹⁰Parameter value applies to DA0–12, DBA0–1, DQ0–15, DQ80–1, DQM0–1, DCLK1–2, \overline{DCLK1-2}, \overline{DCS0-1}, DCLKE, \overline{DRAS}, \overline{DCAS}, and \overline{DWE} pins only.

 $^{^{11}}$ Certain ADSP-BF542/4/7/8/9 processor pins are 5.0 V tolerant (accept up to 5.5 V maximum V_{IH} when power is applied to V_{DDEXT} pins). Voltage compliance on outputs (V_{OH}) depends on the input V_{DDEXT} , because V_{OH} (maximum) approximately equals V_{DDEXT} (maximum). The 5.0 V tolerance feature applies to PB0, PB1, PE14, PE15, PG15–11, PH6, and PH7 pins only. The 5.0 V tolerance exists only when power is applied to the V_{DDEXT} pins. The PB0, PB1, PE14, and PE15 pins are open drain (regardless of pin functionality) and therefore require a pullup resistor. Consult the I^2 C specification version 2.1 for the proper resistor value and other open drain pin electrical parameters.

¹²See Absolute Maximum Ratings.

 $^{^{13}} Parameter\ value\ applies\ to\ all\ input\ and\ bi-directional\ pins,\ except\ PB0,\ PB1,\ PE14,\ PE15,\ PG15-11,\ PH6,\ and\ PH7.$

 $^{^{14}\}mbox{Parameter}$ value applies to the following pins only: PB0, PB1, PE14, PE15, PG15–11, PH6, and PH7.

 $^{^{15}}T_j$ must meet the following conditions during OTP memory programming operations: $0^{\circ}C < T_j < 55^{\circ}C$. During OTP memory read operations, T_j should meet the conditions specified in the operating conditions table.

ELECTRICAL CHARACTERISTICS

| Parameter | | Test Conditions | Min | Typical | Max | Unit |
|-------------------------------|---|--|------|-----------------------|------|------|
| V_{OH} | High Level Output Voltage for 3.3V I/O ¹ | @ $V_{DDEXT} = 2.7V$, $I_{OH} = -0.5 \text{ mA}$ | 2.4 | | | V |

| I _{DDRTC} | TBD | TBD | | TBD | | μΑ |

¹ Applies to output and bidirectional pins, except the pins listed in table note 10 of the Operating Conditions table.

ESD SENSITIVITY

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

² Applies to output and bidirectional pins listed in table note 10 of the Operating Conditions table.

³ Applies to input pins except JTAG inputs.

⁴ Applies to JTAG input pins (TCK, TDI, TMS, TRST).

⁵ Absolute value.

 $^{^6}$ For DDR pins (DQ0-15, DQS0-1), test conditions are $\rm V_{DDDDR}$ = Maximum, $\rm V_{IN}$ = $\rm V_{DDDDR}$ Maximum.

⁷ Applies to three-statable pins.

⁸ Guaranteed, but not tested.

ABSOLUTE MAXIMUM RATINGS

| Internal (Core) Supply Voltage ¹ (V _{DDINT}) | -0.3 V to +1.43 V |
|---|-------------------------------------|
| External (I/O) Supply Voltage ¹ (V _{DDEXT}) | -0.3 V to +3.8 V |
| Input Voltage ^{1,2, 3} | -0.5 V to +3.6 V |
| Output Voltage Swing ¹ | -0.5 V to V _{DDEXT} +0.5 V |
| Load Capacitance ¹ | 200 pF |
| Storage Temperature Range ¹ | -65°C to +150°C |
| Junction Temperature Underbias ¹ | +125°C |

¹ Stresses greater than those listed above may cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions greater than those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 13. Maximum Duty Cycle for Input¹ Transient Voltage

| V _{IN} Max (V) | V _{IN} Min (V) | Maximum Duty Cycle |
|-------------------------|-------------------------|--------------------|
| 3.63 | -0.33 | 100% |
| 3.80 | -0.50 | 48% |
| 3.90 | -0.60 | 30% |
| 4.00 | -0.70 | 20% |
| 4.10 | -0.80 | 10% |
| 4.20 | -0.90 | 8% |
| 4.30 | -1.00 | 5% |

¹ Does not apply to CLKIN. Absolute maximum for pins PBO, PB1, PE14, PE15, PG15-11, PH6, AND PH7 is +5.5V.

PACKAGE INFORMATION

The information presented in Figure 8 and Table 14 provides information about how to read the package brand and relate it to specific product features. For a complete listing of product offerings, see the Ordering Guide on Page 82.

Figure 8. Product Information on Package

Table 14. Package Information

| | T |
|------------|---------------------|
| Brand Key | Description |
| t | Temperature Range |
| рр | Package Type |
| Z | RoHS Compliant part |
| сс | See Ordering Guide |
| vvvvvv.x-q | Assembly Lot Code |
| n.n | Silicon Revision |
| yyww | Date Code |

 $^{^2}$ Applies to all bidirectional and input only pins except PB0, PB1, PE14, PE15, PG15–11, PH6, and PH7. Absolute maximum input voltage range on pins PB0, PB1, PE14, PE15, PG15–11, PH6, and PH7 is –0.5 V to +5.5 V.

 $^{^3}$ Pins USB_DP, USB_DM, and USB_VBUS are 5 V tolerant when VDDUSB is powered according to the operating conditions table. If VDDUSB supply voltage does not meet the specification in the operating conditions table, these pins could suffer long term damage when driven to +5V. If this condition is seen in the application, it can be corrected with additional circuitry to use the external host to power only the $\rm V_{DDUSB}$ pins. Contact factory for application detail and reliability information.

TIMING SPECIFICATIONS

Table 15, Table 16, Table 17, and Table 18 describe the timing requirements for the ADSP-BF542/4/7/8/9 processor clocks. Take care in selecting MSEL, SSEL, and CSEL ratios so as not to exceed the maximum core clock and system clock. Table 19

describes phase-locked loop operating conditions. Table 20 and Figure 9 describe Clock Input and Reset Timing. Table 21 describes Clock Out Timing.

Clock Signals

Table 15. System Clock Requirements

| Parameter | Condition | Minimum | Maximum | Unit |
|--------------------|--|---------|---------|------|
| f _{SCLK} | $V_{DDEXT} = 3.3 \text{ V}, V_{DDINT} \ge TBD$ | | 133 | MHz |
| f_{SCLK} | $V_{DDEXT} = 3.3 \text{ V}, V_{DDINT} < TBD$ | | 100 | MHz |
| f_{SCLK} | $V_{DDEXT} = 2.5 \text{ V}, V_{DDINT} \ge TBD$ | | 133 | MHz |
| f_{SCLK} | $V_{DDEXT} = 2.5 \text{ V}, V_{DDINT} < TBD$ | | 100 | MHz |
| t _{SCLKH} | CLKOUT Width High | 2.5 | | ns |
| t _{SCLKL} | CLKOUT Width Low | 2.5 | | ns |

Table 16. Core Clock Requirements—600 MHz Speed Grade¹

| Parameter | | Minimum | Maximum | Unit |
|-------------------|--|---------|---------|------|
| f _{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | 600 | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V) | | TBD | MHz |

¹The speed grade of a given part may be seen on the Ordering Guide on Page 82. It stands for the maximum allowed CCLK frequency at V_{DDINT} = minimum and the maximum allowed VCO frequency at any supply voltage.

Table 17. Core Clock Requirements—533 MHz Speed Grade¹

| Parameter | | Minimum | Maximum | Unit |
|------------|--|---------|---------|------|
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =1.188 V minimum) | | 533 | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V) | | TBD | MHz |

¹ The speed grade of a given part may be seen on the Ordering Guide on Page 82. It stands for the maximum allowed CCLK frequency at V_{DDINT} = minimum and the maximum allowed VCO frequency at any supply voltage.

Table 18. Core Clock Requirements—400 MHz Speed Grade¹

| Parameter | | Minimum | Maximum | Unit |
|-------------------|---|---------|---------|------|
| f _{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | 400 | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} = TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V minimum) | | TBD | MHz |
| f_{CCLK} | Core Clock Frequency (V _{DDINT} =TBD V) | | TBD | MHz |

 $^{^{1}}$ The speed grade of a given part may be seen on the Ordering Guide on Page 82. It stands for the maximum allowed CCLK frequency at $V_{\rm DDINT}$ = minimum and the maximum allowed VCO frequency at any supply voltage.

Table 19. Phase-Locked Loop Operating Conditions

| Parameter | | Minimum | Maximum | Unit |
|-----------|---|---------|--------------------------|------|
| f_{VCO} | Voltage Controlled Oscillator (VCO) Frequency | 50 | Speed Grade ¹ | MHz |

¹ The speed grade of a given part may be seen on the "Ordering Guide" on page 82. It stands for the Maximum allowed CCLK frequency at V_{DDINT} = minimum and the maximum allowed VCO frequency at any supply voltage.

Table 20. Clock Input and Reset Timing

| Parameter | | Minimum | Maximum | Unit |
|----------------------|--|-----------------------|----------------|------|
| Timing Requ | irements | | | |
| t_{CKIN} | CLKIN Period ^{1,2,3,4} | 20.0 | 100.0 | ns |
| t _{CKINL} | CLKIN Low Pulse ² | 8.0 | | ns |
| t _{CKINH} | CLKIN High Pulse ² | 8.0 | | ns |
| t _{BUFDLAY} | CLKIN to CLKBUF Delay | | 10 | ns |
| t _{WRST} | RESET Asserted Pulsewidth Low ⁵ | 11 t _{CKIN} | | ns |
| t_{RHWFT} | RESET High to First HWAIT/HWAITA transition (Boot Host Wait Mode) ⁶ | TBD t _{CKIN} | | ns |
| t _{RHWFT} | RESET High to First HWAIT/HWAITA transition (Reset Output Mode) ⁷ | TBD t _{CKIN} | TBD t_{CKIN} | ns |

¹ Combinations of the CLKIN frequency and the PLL clock multiplier must not exceed the allowed fVCO, fCCLK, and fSCLK settings discussed in the previous Clock tables.

⁷When enabled by OTP_RESETOUT_HWAIT bit. If regular HWAIT is not required in an application, the OTP_RESETOUT_HWAIT bit in the same page instructs the HWAIT or HWAITA to simulate Reset Output functionality. Then an external resistor is expected to pull the signal to the reset level, as the pin itself is in high-performance mode during reset.

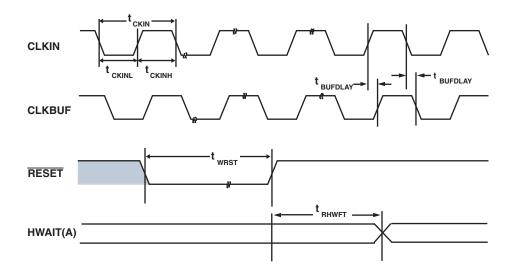

Figure 9. Clock and Reset Timing

² Applies to PLL bypass mode and PLL nonbypass mode.

³ CLKIN frequency and duty cycle must not change on the fly.

⁴ If the DF bit in the PLL_CTL register is set, then the maximum tCKIN period is 50 ns.

⁵ Applies after power-up sequence is complete. At power-up, the processor's internal phase locked loop requires no more than 2000 CLKIN cycles, while RESET is asserted, assuming stable power supplies and CLKIN (not including startup time of external clock oscillator).

⁶ Maximum value varies with OTP memory programming and boot mode.

Table 21. Clock Out Timing

| Paramete | r | Min | Max | Unit |
|--------------------|----------------------------|-----|-----|------|
| Switching (| Characteristics | | | |
| t_{SCLK} | CLKOUT Period ¹ | TBD | | ns |
| t _{SCLKH} | CLKOUT Width High | TBD | | ns |
| t _{SCLKL} | CLKOUT Width Low | TBD | | ns |

 $^{^{1}\}text{The }t_{SCLK}\text{ value is the inverse of the }f_{SCLK}\text{ specification. Reduced supply voltages affect the best-case value of TBD ns listed here.}$

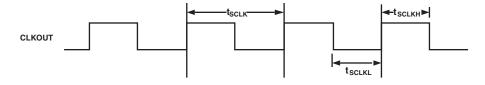

Figure 10. CLKOUT Interface Timing

Asynchronous Memory Read Cycle Timing

Table 22 and Table 23 on Page 40 and Figure 11 and Figure 12 on Page 40 describe asynchronous memory read cycle operations for synchronous and for asynchronous ARDY.

Table 22. Asynchronous Memory Read Cycle Timing with Synchronous ARDY

| Parameter | | Min | Max | Unit |
|----------------------|--|-----|-----|------|
| Timing Requ | uirements | | | |
| t_{SDAT} | DATA15-0 Setup Before CLKOUT | 2.1 | | ns |
| t_{HDAT} | DATA15-0 Hold After CLKOUT | 0.8 | | ns |
| t_{SARDY} | ARDY Setup Before the Falling Edge of CLKOUT | 4.0 | | ns |
| \mathbf{t}_{HARDY} | ARDY Hold After the Falling Edge of CLKOUT | 0.0 | | ns |
| t_{DO} | Output Delay After CLKOUT ¹ | | 6.0 | ns |
| t_{HO} | Output Hold After CLKOUT ¹ | 0.8 | | ns |

 $^{^{1}}$ Output pins include $\overline{AMS3-0}$, $\overline{ABE1-0}$, ADDR19-1, \overline{AOE} , \overline{ARE} .

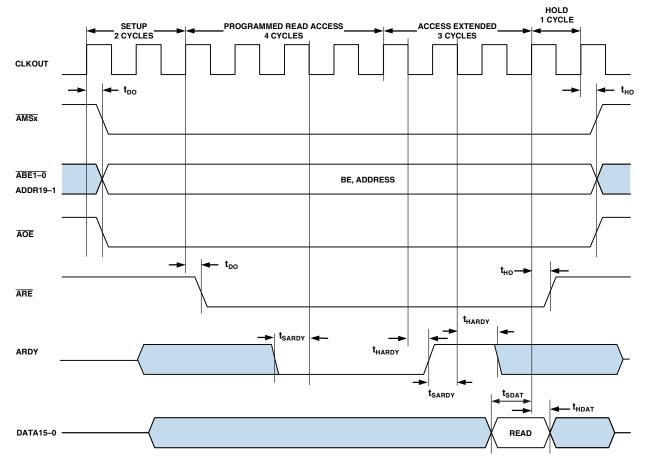

Figure 11. Asynchronous Memory Read Cycle Timing with Synchronous ARDY

Table 23. Asynchronous Memory Read Cycle Timing with Asynchronous ARDY

| Parameter | | Min | Max | Unit |
|-------------------|--|-----|-----------|----------------------|
| Timing Requ | uirements | | | |
| t _{SDAT} | DATA15-0 Setup Before CLKOUT | 2.1 | | ns |
| t _{HDAT} | DATA15-0 Hold After CLKOUT | 0.8 | | ns |
| t _{DANR} | ARDY Negated Delay from AMSx Asserted ¹ | | (S+RA-2)* | t _{sclk} ns |
| t _{HAA} | ARDY Asserted Hold After ARE Negated | 0.0 | | ns |
| t_{DO} | Output Delay After CLKOUT ² | | 6.0 | ns |
| t_{HO} | Output Hold After CLKOUT ² | 0.8 | | ns |

¹S = number of programmed setup cycles, RA = number of programmed read access cycles.

²Output pins include AMS3-0, ABE1-0, ADDR19-1, AOE, ARE.

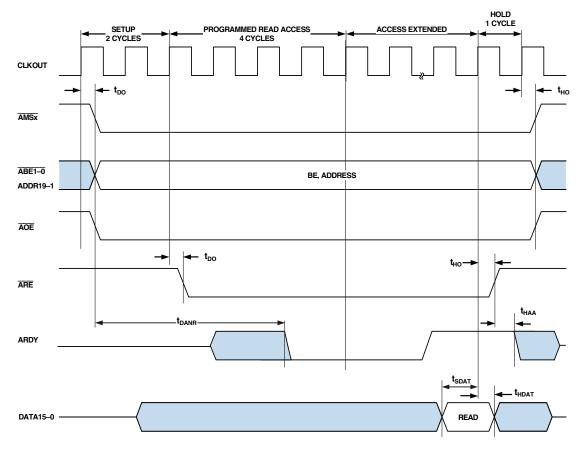

Figure 12. Asynchronous Memory Read Cycle Timing with Asynchronous ARDY

Asynchronous Memory Write Cycle Timing

Table 24 and Table 25 on Page 42 and Figure 13 and Figure 14 on Page 42 describe asynchronous memory write cycle operations for synchronous and for asynchronous ARDY.

Table 24. Asynchronous Memory Write Cycle Timing with Synchronous ARDY

| Parameter | | Min | Max | Unit |
|--------------------|--|-----|-----|------|
| Timing Requ | irements | | | |
| t_{SARDY} | ARDY Setup Before the Falling Edge of CLKOUT | 4.0 | | ns |
| t _{HARDY} | ARDY Hold After the Falling Edge of CLKOUT | 0.0 | | ns |
| Switching Ci | haracteristics | | | |
| t_{DDAT} | DATA15-0 Disable After CLKOUT | | 6.0 | ns |
| t _{ENDAT} | DATA15-0 Enable After CLKOUT | 1.0 | | ns |
| t_{DO} | Output Delay After CLKOUT ¹ | | 6.0 | ns |
| t_{HO} | Output Hold After CLKOUT ¹ | 0.8 | | ns |

¹Output pins include AMS3-0, ABE1-0, ADDR19-1, DATA15-0, AOE, AWE.

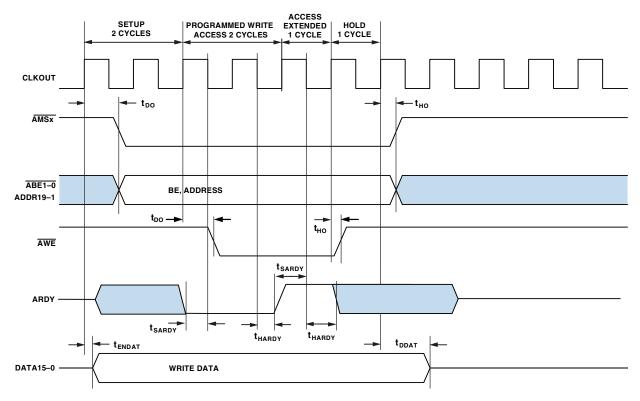

Figure 13. Asynchronous Memory Write Cycle Timing with Synchronous ARDY

Table 25. Asynchronous Memory Write Cycle Timing with Asynchronous ARDY

| Parameter | | Min | Max | Unit |
|---------------------------|--|-----|-------------------|------------------|
| Timing Req | uirements | | | |
| t _{DANR} | ARDY Negated Delay from AMSx Asserted ¹ | | $(S+WA-2)*t_{SC}$ | _{LK} ns |
| \mathbf{t}_{HAA} | ARDY Asserted Hold After ARE Negated | 0.0 | | ns |
| Switching C | haracteristics | | | |
| t _{DDAT} | DATA15 – 0 Disable After CLKOUT | | 6.0 | ns |
| t _{ENDAT} | DATA15 – 0 Enable After CLKOUT | 1.0 | | ns |
| t_{DO} | Output Delay After CLKOUT ² | | 6.0 | ns |
| t_{HO} | Output Hold After CLKOUT ² | 0.8 | | ns |

 $^{^{1}}$ S = number of programmed setup cycles, WA = number of programmed write access cycles.

²Output pins include AMS3-0, ABE1-0, ADDR19-1, DATA15-0, AOE, AWE.

Serial Ports Timing

Table 33 through Table 36 on Page 51 and Figure 20 on Page 52 through Figure 22 on Page 54 describe Serial Port operations.

Table 33. Serial Ports—External Clock

| Parameter | | Min | Max | Unit |
|---------------------|--|------|------|------|
| Timing Requ | uirements | | | |
| t _{SFSE} | TFS/RFS Setup Before TSCLK/RSCLK (externally generated TFS/RFS) ¹ | 3.0 | | ns |
| t _{HFSE} | TFS/RFS Hold After TSCLK/RSCLK (externally generated TFS/RFS) ¹ | 3.0 | | ns |
| t_{SDRE} | Receive Data Setup Before RSCLK ¹ | 3.0 | | ns |
| t_{HDRE} | Receive Data Hold After RSCLK ¹ | 3.0 | | ns |
| t_{SCLKEW} | TSCLK/RSCLK Width | 4.5 | | ns |
| t _{SCLKE} | TSCLK/RSCLK Period | 15.0 | | ns |
| t_{RCLKE} | RSCLK Period ² | 11.1 | | ns |
| Switching Ci | haracteristics | | | |
| t_{DFSE} | TFS/RFS Delay After TSCLK/RSCLK (Internally Generated TFS/RFS) ³ | | 10.0 | ns |
| t _{HOFSE} | TFS/RFS Hold After TSCLK/RSCLK (Internally Generated TFS/RFS ³ | 0.0 | | ns |
| t_{DDTE} | Transmit Data Delay After TSCLK ³ | | 10.0 | ns |
| t _{HDTE} | Transmit Data Hold After TSCLK ³ | 0.0 | | ns |

 $^{^{\}rm 1}$ Referenced to sample edge.

Table 34. Serial Ports—Internal Clock

| Parameter | | Min | Max | Unit |
|---------------------|--|------|-----|------|
| Timing Requ | irements | | | |
| t _{SFSI} | TFS/RFS Setup Before TSCLK/RSCLK (externally generated TFS/RFS) ¹ | 8.0 | | ns |
| t _{HFSI} | TFS/RFS Hold After TSCLK/RSCLK (externally generated TFS/RFS) ¹ | -1.5 | | ns |
| t_{SDRI} | Receive Data Setup Before RSCLK ¹ | 8.0 | | ns |
| t_{HDRI} | Receive Data Hold After RSCLK ¹ | -1.5 | | ns |
| t _{SCLKEW} | TSCLK/RSCLK Width | 4.5 | | ns |
| t _{SCLKE} | TSCLK/RSCLK Period | 15.0 | | ns |
| Switching Ci | haracteristics | | | |
| t _{DFSI} | TFS/RFS Delay After TSCLK/RSCLK (Internally Generated TFS/RFS) ² | | 3.0 | ns |
| t _{HOFSI} | TFS/RFS Hold After TSCLK/RSCLK (Internally Generated TFS/RFS) ² | -1.0 | | ns |
| t _{DDTI} | Transmit Data Delay After TSCLK ² | | 3.0 | ns |
| t _{HDTI} | Transmit Data Hold After TSCLK ² | -2.0 | | ns |
| t _{SCLKIW} | TSCLK/RSCLK Width | 4.5 | | ns |

¹ Referenced to sample edge.

² For serial port receive with external clock and external frame sync only.

 $^{^{\}rm 3}\,\text{Referenced}$ to drive edge.

² Referenced to drive edge.

Table 35. Serial Ports—Enable and Three-State

| Parameter | | Min | Max | Unit |
|--------------------|---|------|------|------|
| Switching C | haracteristics | | | |
| t _{DTENE} | Data Enable Delay from External TSCLK ¹ | 0 | | ns |
| t _{DDTTE} | Data Disable Delay from External TSCLK ¹ | | 10.0 | ns |
| t _{DTENI} | Data Enable Delay from Internal TSCLK ¹ | -2.0 | | ns |
| t _{DDTTI} | Data Disable Delay from Internal TSCLK ¹ | | 3.0 | ns |

 $^{^{\}rm 1}\,\mathrm{Referenced}$ to drive edge.

Table 36. External Late Frame Sync

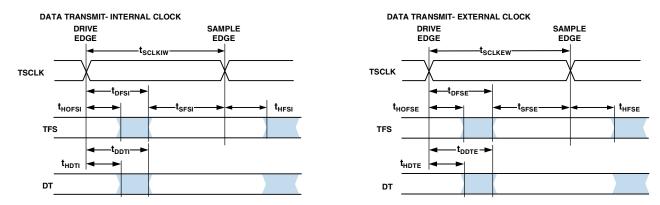

| Parameter | | Min | Max | Unit |
|----------------------|---|-----|------|------|
| Switching Ch | paracteristics | | | |
| t _{DDTLFSE} | Data Delay from Late External TFS or External RFS with MCE = 1, MFD = $0^{1,2}$ | | 10.0 | ns |
| t _{DTENLFS} | Data Enable from late Frame Sync or MCE = 1, MFD = $0^{1,2}$ | 0 | | ns |

 $^{^{1}\,\}text{MCE}$ = 1, TFS enable and TFS valid follow t_{DTENLFS} and $t_{\text{DDTLFSE}}.$

 $^{^2}$ If external RFS/TFS setup to RSCLK/TSCLK > $t_{SCLKE}/2$, then $t_{DDTE/I}$ and $t_{DTENE/I}$ apply; otherwise $t_{DDTLFSE}$ and t_{DTENES} apply.

NOTE: EITHER THE RISING EDGE OR FALLING EDGE OF RCLK OR TCLK CAN BE USED AS THE ACTIVE SAMPLING EDGE.

NOTE: EITHER THE RISING EDGE OR FALLING EDGE OF RCLK OR TCLK CAN BE USED AS THE ACTIVE SAMPLING EDGE.

Serial Peripheral Interface (SPI) Port—Master Timing

Table 37 and Figure 23 describe SPI port master operations.

Table 37. Serial Peripheral Interface (SPI) Port—Master Timing

| Parameter | | Minimum | Minimum Maximum | |
|----------------------|---|--------------------------|-----------------|----|
| Timing Requ | irements | | | |
| t _{SSPIDM} | Data input valid to SCK edge (data input setup) | 7.5 | | ns |
| t _{HSPIDM} | SCK sampling edge to data input invalid | -1.5 | | ns |
| Switching Ch | naracteristics | | | |
| t _{SDSCIM} | SPISELx low to first SCK edge (x=0 or 1) | 2t _{SCLK} – 1.5 | | ns |
| t _{SPICHM} | Serial clock high period | 2t _{SCLK} – 1.5 | | ns |
| t _{SPICLM} | Serial clock low period | 2t _{SCLK} – 1.5 | | ns |
| t _{SPICLK} | Serial clock period | 4t _{SCLK} – 1.5 | | ns |
| t_{HDSM} | Last SCK edge to SPISELx high (x=0 or 1) | 2t _{SCLK} – 1.5 | | ns |
| t_{SPITDM} | Sequential transfer delay | 2t _{SCLK} – 1.5 | | ns |
| t _{DDSPIDM} | SCK edge to data out valid (data out delay) | 0 | 6 | ns |
| t _{HDSPIDM} | SCK edge to data out invalid (data out hold) | -1.0 | 4.0 | ns |

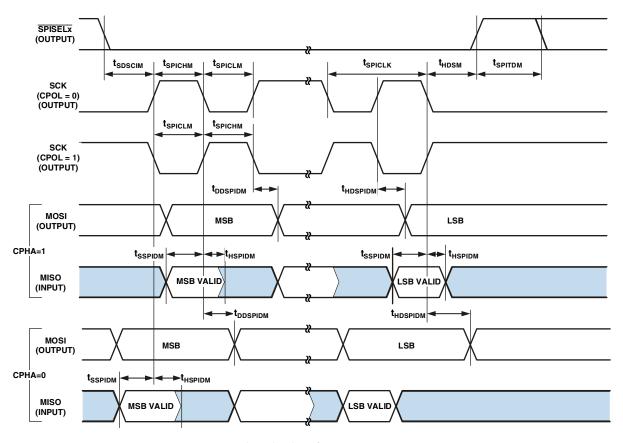

Figure 23. Serial Peripheral Interface (SPI) Port—Master Timing

Serial Peripheral Interface (SPI) Port—Slave Timing

Table 38 and Figure 24 describe SPI port slave operations.

Table 38. Serial Peripheral Interface (SPI) Port—Slave Timing

| Parameter | eter Minimum Maximum | | Maximum | Unit |
|---------------------|---|--------------------------|---------|------|
| Timing Requ | uirements | | | |
| t _{SPICHS} | Serial clock high period | 2t _{SCLK} – 1.5 | | ns |
| t _{SPICLS} | Serial clock low period | 2t _{SCLK} – 1.5 | | ns |
| t _{SPICLK} | Serial clock period | 4t _{SCLK} – 1.5 | | ns |
| t _{HDS} | Last SCK edge to SPISS not asserted | 2t _{SCLK} – 1.5 | | ns |
| t _{SPITDS} | Sequential Transfer Delay | 2t _{SCLK} – 1.5 | | ns |
| t _{SDSCI} | SPISS assertion to first SCK edge | 2t _{SCLK} – 1.5 | | ns |
| t _{SSPID} | Data input valid to SCK edge (data input setup) | 1.6 | | ns |
| t _{HSPID} | SCK sampling edge to data input invalid | 1.6 | | ns |
| Switching Ci | haracteristics | | | |
| t _{DSOE} | SPISS assertion to data out active | 0 | 8 | ns |
| t _{DSDHI} | SPISS deassertion to data high impedance | 0 | 8 | ns |
| t _{DDSPID} | SCK edge to data out valid (data out delay) | 0 | 10 | ns |
| t _{HDSPID} | SCK edge to data out invalid (data out hold) | О | 10 | ns |

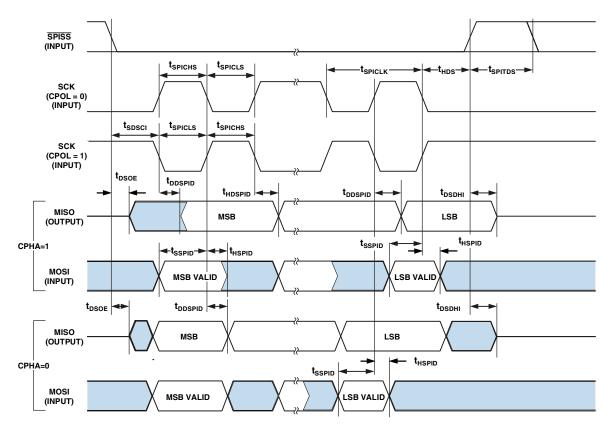

Figure 24. Serial Peripheral Interface (SPI) Port—Slave Timing

Universal Asynchronous Receiver-Transmitter (UART) Ports—Receive and Transmit Timing

Figure 25 describes the UART ports receive and transmit operations. The maximum baud rate is SCLK/16. There is some latency between the generation of internal UART interrupts

and the external data operations. These latencies are negligible at the data transmission rates for the UART.

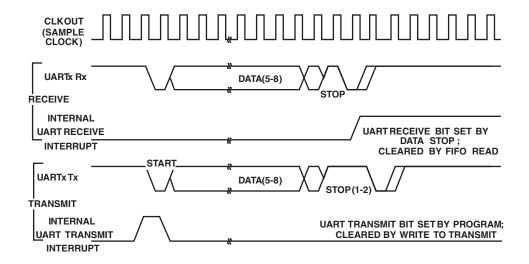

Figure 25. UART Ports—Receive and Transmit Timing

General-Purpose Port Timing

Table 39 and Figure 26 describe general-purpose port operations.

Table 39. General-Purpose Port Timing

| Parameter | | Minimum | Maximum | Unit |
|-------------------|---|-----------------------|---------|------|
| Timing Requireme | nt | | | |
| t _{WFI} | General-Purpose Port Pin Input Pulse Width | t _{SCLK} + 1 | | ns |
| Switching Charact | eristic | | | |
| t_{GPOD} | General-Purpose Port Pin Output Delay from CLKOUT Low | 0 | 6 | ns |

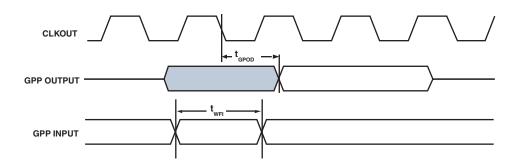

Figure 26. General-Purpose Port Timing

Rev. PrG | Page 57 of 82 | December 2007

Timer Cycle Timing

Table 40 and Figure 27 describe timer expired operations. The input signal is asynchronous in "width capture mode" and "external clock mode" and has an absolute maximum input frequency of ($f_{SCLK}/2$) MHz.

Table 40. Timer Cycle Timing

| Parametei | rameter Minimum Maximui | | Unit |
|--------------------|---|--|------|
| Timing Cha | racteristics | | |
| t_WL | Timer Pulse Width Input Low (Measured In SCLK Cycles) ¹ | 1t _{SCLK} | ns |
| t_WH | Timer Pulse Width Input High (Measured In SCLK Cycles) ¹ | 1t _{SCLK} | ns |
| \mathbf{t}_{TIS} | Timer Input Setup Time Before CLKOUT Low ² | 5 | ns |
| t_{TIH} | Timer Input Hold Time After CLKOUT Low ² | -2 | ns |
| Switching C | Characteristic | | |
| t_{HTO} | Timer Pulse Width Output (Measured In SCLK Cycles) | 1t _{SCLK} (2 ³² –1)t _{SCLK} | ns |
| t _{TOD} | Timer Output Update Delay After CLKOUT High | 6 | ns |

¹ The minimum pulse widths apply for TMRx signals in width capture and external clock modes.

²Either a valid setup and hold time or a valid pulse width is sufficient. There is no need to resynchronize timer flag inputs.

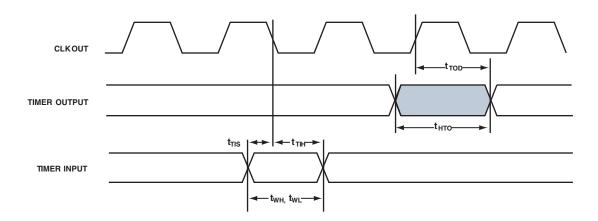

Figure 27. Timer Cycle Timing

ATA/ATAPI Controller Timing

Table 41. ATA/ATAPI Controller Timing

| Parameter | | Minimum | Maximum | Unit |
|---------------|--------------|---------|---------|------|
| Timing Requir | rements | | | |
| TBD | TBD | TBD | | ns |
| Switching Cha | aracteristic | | | |
| TBD | TBD | | TBD | ns |

| TBD | TBD | | TBD | ns |

Figure 30. SD/SDIO Controller Timing

MXVR Timing

Table 44 and Table 45 describe the MXVR timing requirements.

Table 44. MXVR Timing—MXI Center Frequency Requirements

| Parameter | | Fs = 38 KHz | Fs = 44.1 KHz | Fs = 48 KHz | Unit |
|-----------------------|-------------------------------|-------------|---------------|-------------|------|
| f _{MXI_256} | MXI Center Frequency (256Fs) | 9.728 | 11.2896 | 12.288 | MHz |
| f_{MXI_384} | MXI Center Frequency (384Fs) | 14.592 | 16.9344 | 18.432 | MHz |
| f _{MXI_512} | MXI Center Frequency (512Fs) | 19.456 | 22.5792 | 24.576 | MHz |
| f _{MXI_1024} | MXI Center Frequency (1024Fs) | 38.912 | 45.1584 | 49.152 | MHz |

Table 45. MXVR Timing— MXI Clock Requirements

| Paramete | Parameter | | Max | Unit |
|------------|--|------|------|------|
| Timing Red | quirements | | | |
| FS_{MXI} | MXI Clock Frequency Stability | -50 | +50 | ppm |
| FT_{MXI} | MXI Frequency Tolerance Over Temperature | -300 | +300 | ppm |
| DC_{MXI} | MXI Clock Duty Cycle | 40 | 60 | % |

HOSTDP A/C Timing- Host Read Cycle

Table 46 describe the HOSTDP A/C Host Read Cycle timing requirements.

Table 46. Host Read Cycle Timing Requirements

| Parameter | | Minimum | Maximum | Units |
|----------------------|--|---|-------------------|-------|
| Timing Requi | rements | | | |
| t _{SADRDL} | HOST_ADDR and Host_CE Setup before Host_RD assertion | 1.5 * t _{sclk} | | ns |
| t_{HADRDH} | HOST_ADDR and Host_CE Hold after Host_RD assertion | 2.5 | | ns |
| t_{RDWL} | Host_RD pulse width low | $t_{DRDYRDL} + t_{RDYPRD} + t_{DRDHRDY}$ (ACK mode) | | ns |
| | | 1.5 * t _{sclk} + 8.7 (INT mode) | | ns |
| t_{RDWH} | Host_RD pulse width high | 2 * t _{sclk} | | ns |
| t _{DRDHRDY} | Host_RD de-assertion delay after Host_ACK de-assertion | TBD | | ns |
| Switching Ch | aracteristics | | | |
| t _{SDATRDY} | Data valid after Host_ACK assertion | | t _{sclk} | ns |
| t _{DRDYRDL} | Host_ACK assertion delay after Host_RD | 1.5 * t _{sclk} + 8.7 | | ns |
| t _{RDYPRD} | Host_ACK low pulse-width for Read access | Data Delay | | ns |
| t _{HDARWH} | Data disable after Host_RD | 1.0 | | ns |

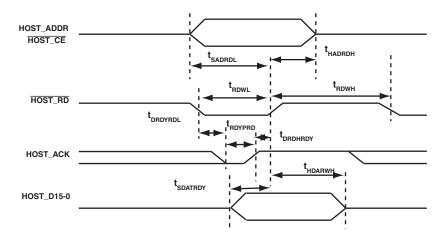

Figure 31. HOSTDP A/C- Host Read Cycle

HOSTDP A/C Timing- Host Write Cycle

Table 47 describes the HOSTDP A/C Host Write Cycle timing requirements.

Table 47. Host Write Cycle Timing Requirements

| Parameter | | Minimum | Maximum | Units |
|----------------------|--|---|-------------------------|-------|
| Timing Requ | irements | | | |
| t _{sadwrh} | HOST_ADDR/Host_CE Setup before Host_WR | (1.5 * t _{sclk})+ 10.8 | | ns |
| t_{HADWRH} | HOST_ADDR/Host_CE Hold after Host_WR | 2.5 | | ns |
| t _{wrwL} | Host_WR pulse width low | $t_{DRDYWRL} + t_{RDYPRD} + t_{DWRHRDY}$ (ACK mode) | | |
| | | 1.5 * t _{sclk} + 8.7 (INT mode) | | ns |
| t_{WRWH} | Host_WR pulse width high | 2 * t _{sclk} | | ns |
| t _{DWRHRDY} | Host_WR de-assertion delay after Host_ACK de-assertion | TBD | | ns |
| t_{HDATWH} | Data Hold after Host_WR de-assertion | 2.5 | | ns |
| t _{sdatwh} | Data Setup before Host_WR de-assertion | 2.5 | | ns |
| Switching Ch | naracteristics | | | |
| t _{DRDYWRL} | Host_ACK low delay after Host_WR/Host_CE | | 1.5 * t _{sclk} | ns |
| t_{RDYPWR} | Host_ACK low pulse-width for Write access | | | |

Table 48. OTP Timing Parameters¹

| Parameter | | Minimum | Maximum | Unit |
|-------------------|-------------------------------------|---------|---------|------|
| t _{FACC} | OTP Memory Bit Read Access Time | 400 | | ns |
| t_{RPGM} | OTP Memory Charge Pump Release Time | 1 | | μs |
| t_{CPS} | OTP Memory Charge Pump Setup Time | | 0 | μs |
| t_CPH | OTP Memory Charge Pump Hold Time | | 0 | μs |
| t _{PGM} | OTP Memory Bit Program Time | 10 | | μs |

 $^{^{1}} These \ parameters \ are \ programmed \ into \ the \ OTP_TIMING \ register. \ See \ ADSP-BF54x \ Blackfin \ Processor \ Hardware \ Reference \ for \ details.$

JTAG Test And Emulation Port Timing

Table 49 and Figure 33 describe JTAG port operations.

Table 49. JTAG Port Timing

| Parameter | Parameter Parameter | | Maximum | Unit |
|-------------------|---|----|---------|------|
| Timing Para | ameters | | | |
| t_{TCK} | TCK Period | 20 | | ns |
| t_{STAP} | TDI, TMS Setup Before TCK High | 4 | | ns |
| t _{HTAP} | TDI, TMS Hold After TCK High | 4 | | ns |
| t_{SSYS} | System Inputs Setup Before TCK High ¹ | 4 | | ns |
| t _{HSYS} | System Inputs Hold After TCK High ¹ | 5 | | ns |
| t_{TRSTW} | TRST Pulsewidth ² (measured in TCK cycles) | 4 | | TCK |
| Switching C | haracteristics | | | |
| t_{DTDO} | TDO Delay from TCK Low | | 10 | ns |
| t _{DSYS} | System Outputs Delay After TCK Low ³ | 0 | 12 | ns |

 $^{^1} System \ Inputs = PA15-0, PB14-0, PC15-0, PD15-0, PE15-0, PF15-0, PG15-0, PH13-0, PI15-0, PJ14-0, DQ15-0, DQS1-0, D15-0, ATAPI_PDIAG, CLKIN, \overline{RESET}, \overline{NMI}, BMODE3-0, MFS, MLF_P, and MLF_M.$

³ System Outputs=PA15-0, PB14-0, PC15-0, PD15-0, PE15-0, PF15-0, PG15-0, PH13-0, PI15-0, PJ14-0, DQ15-0, DQS1-0, D15-0, DA12-0, DBA1-0, DQM1-0, DCLK0-1, DCLK0-1, DCS1-0, DCS1-0, DCAS, DWE, AMS3-0, ABE1-0, AOE, ARE, AWE, EMU, CLKOUT, CLKBUF, EXT_WAKE.

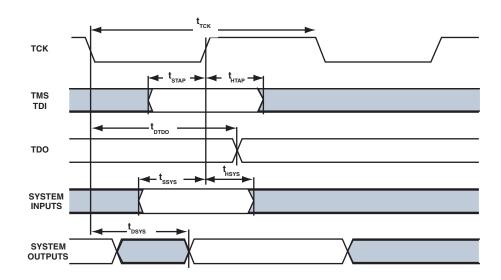

Figure 33. JTAG Port Timing

² 50 MHz Maximum

POWER DISSIPATION

Total power dissipation has two components: one due to internal circuitry (P_{INT}) and one due to the switching of external output drivers (P_{EXT}). Table 50 through Table 52 show the power dissipation for internal circuitry (V_{DDINT}).

See the *ADSP-BF549 Blackfin Processor Hardware Reference* for definitions of the various operating modes and for instructions on how to minimize system power.

Many operating conditions can affect power dissipation. System designers should refer to *Estimating Power for ADSP-BF542/BF544/BF547/BF548/BF549 Blackfin Processors (EE-TBD)* on the Analog Devices website (www.analog.com)—use site search on "EE-TBD." This document provides detailed information for optimizing your design for lowest power.

Table 50. Internal Power Dissipation (Hibernate mode)

| | I _{DD} (nominal) | Unit |
|---------------------------------|---------------------------|------|
| I _{DDHIBERNATE} 1 | TBD | μΑ |
| I _{DDRTC} ² | TBD | μΑ |

 $^{^{1}}$ Measured at $V_{DDEXT} = 3.65 \text{ V}$ with voltage regulator off ($V_{DDINT} = 0 \text{ V}$).

Table 51. Internal Power Dissipation (Deep Sleep mode)

| V _{DDINT} ¹ | I _{DD} (nominal ²) | Unit |
|---------------------------------|---|------|
| 0.8 | TBD | mA |
| 0.9 | TBD | mA |
| 1.0 | TBD | mA |
| 1.1 | TBD | mA |
| 1.26 | TBD | mA |

 $^{^{1}}$ Assumes V_{DDINT} is regulated externally.

Table 52. Internal Power Dissipation (Full On¹ mode)

| V _{DDINT} ² @ f _{CCLK} | I _{DD} (nominal ³) | Unit |
|--|---|------|
| 0.8 @ TBD MHz | TBD | mA |
| 0.8 @ TBD MHz | TBD | mA |
| 0.9 @ TBD MHz | TBD | mA |
| 1.0 @ TBD MHz | TBD | mA |
| 1.1 @ TBD MHz | TBD | mA |
| 1.26 @ TBD MHz | TBD | mA |

¹ Processor executing 75% dual MAC, 25% ADD with moderate data bus activity.

TEST CONDITIONS

All timing parameters appearing in this data sheet were measured under the conditions described in this section.

Output Enable Time

Output pins are considered to be enabled when they have made a transition from a high impedance state to the point when they start driving. The output enable time $t_{\rm ENA}$ is the interval from the point when a reference signal reaches a high or low voltage level to the point when the output starts driving as shown in the Output Enable/Disable diagram (Figure 34). The time $t_{\rm ENA_MEASURED}$ is the interval from when the reference signal switches to when the output voltage reaches 2.0 V (output high) or 1.0 V (output low). Time $t_{\rm TRIP}$ is the interval from when the output starts driving to when the output reaches the 1.0 V or 2.0 V trip voltage. Time $t_{\rm ENA}$ is calculated as shown in the equation:

$$t_{ENA} = t_{ENA \ MEASURED} - t_{TRIP}$$

If multiple pins (such as the data bus) are enabled, the measurement value is that of the first pin to start driving.

Output Disable Time

Output pins are considered to be disabled when they stop driving, go into a high impedance state, and start to decay from their output high or low voltage. The time for the voltage on the bus to decay by ΔV is dependent on the capacitive load, C_L and the load current, $I_L.$ This decay time can be approximated by the equation:

$$t_{DECAY} = (C_L \Delta V) / I_L$$

The output disable time t_{DIS} is the difference between $t_{DIS_MEASURED}$ and t_{DECAY} as shown in Figure 34. The time $t_{DIS_MEASURED}$ is the interval from when the reference signal switches to when the output voltage decays ΔV from the measured output high or output low voltage. The time t_{DECAY} is calculated with test loads C_L and I_L , and with ΔV equal to 0.5 V.

 $^{^{2}}$ Measured at $V_{DDRTC} = 3.3 \text{ V}$ at 25°C.

² Nominal assumes an operating temperature of 25°C.

 $^{^2\,}Assumes\,V_{DDINT}$ is regulated externally.

³ Nominal assumes an operating temperature of 25°C.

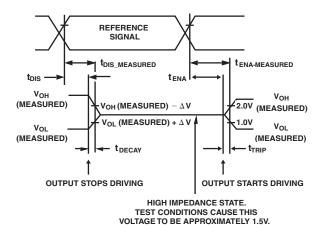

Figure 34. Output Enable/Disable

Example System Hold Time Calculation

To determine the data output hold time in a particular system, first calculate $t_{\rm DECAY}$ using the equation given above. Choose ΔV to be the difference between the ADSP-BF542/4/7/8/9 processor's output voltage and the input threshold for the device requiring the hold time. A typical ΔV will be 0.4 V. C_L is the total bus capacitance (per data line), and I_L is the total leakage or three-state current (per data line). The hold time will be $t_{\rm DECAY}$ plus the minimum disable time (for example, $t_{\rm DDAT}$ for an asynchronous memory write cycle).

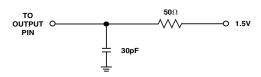

Figure 35. Equivalent Device Loading for AC Measurements (Includes All Fixtures)

Figure 36. Voltage Reference Levels for AC Measurements (Except Output Enable/Disable)

ENVIRONMENTAL CONDITIONS

To determine the junction temperature on the application printed circuit board use:

$$T_J = T_{CASE} + (\Psi_{JT} \times P_D)$$

where:

 $T_I = Junction temperature (°C)$

 T_{CASE} = Case temperature (°C) measured by customer at top center of package.

 Ψ_{IT} = From Table 53

 P_D = Power dissipation (see Power Dissipation on Page 64 for the method to calculate P_D)

Values of θ_{JA} are provided for package comparison and printed circuit board design considerations. θ_{JA} can be used for a first order approximation of T_I by the equation:

$$T_I = T_A + (\theta_{IA} \times P_D)$$

where:

 $T_A = Ambient temperature (°C)$

Values of θ_{JC} are provided for package comparison and printed circuit board design considerations when an external heatsink is required.

Values of θ_{JB} are provided for package comparison and printed circuit board design considerations.

In Table 53, airflow measurements comply with JEDEC standards JESD51-2 and JESD51-6, and the junction-to-board measurement complies with JESD51-8. The junction-to-case measurement complies with MIL-STD-883 (Method 1012.1). All measurements use a 2S2P JEDEC test board.

Table 53. Thermal Characteristics, 400-Ball CSP_BGA

| Parameter | Condition | Typical | Unit |
|----------------------|-----------------------|---------|------|
| θ_{JA} | 0 linear m/s air flow | 18.4 | °C/W |
| | 1 linear m/s air flow | 15.8 | °C/W |
| | 2 linear m/s air flow | 15.0 | °C/W |
| θ_{JB} | | 9.75 | °C/W |
| θ_{JC} | | 6.37 | °C/W |
| $\Psi_{ m JT}$ | 0 linear m/s air flow | 0.27 | °C/W |
| | 1 linear m/s air flow | 0.60 | °C/W |
| | 2 linear m/s air flow | 0.66 | °C/W |

In Table 54, airflow measurements comply with JEDEC standards JESD51-2 and JESD51-6, and the junction-to-board measurement complies with JESD51-8. The junction-to-case measurement complies with MIL-STD-883 (Method 1012.1). All measurements use a 2S2P JEDEC test board.

Table 54. Thermal Characteristics, 360-Ball PBGA

| Parameter | Condition | Typical | Unit |
|---------------|-----------------------|---------|------|
| θ_{JA} | 0 linear m/s air flow | 17.5 | °C/W |
| | 1 linear m/s air flow | 15.2 | °C/W |
| | 2 linear m/s air flow | 14.4 | °C/W |
| θ_{JB} | | 7.2 | °C/W |
| θ_{JC} | | 5.9 | °C/W |
| Ψ_{JT} | 0 linear m/s air flow | 0.22 | °C/W |
| | 1 linear m/s air flow | 0.35 | °C/W |
| | 2 linear m/s air flow | 0.42 | °C/W |

400-BALL CSP_BGA PACKAGE

Table 55 lists the CSP_BGA package by signal for the ADSP-BF549. Table 56 on Page 70 lists the CSP_BGA package by ball number.

OUTLINE DIMENSIONS

Dimensions for the 17 mm \times 17 mm CSP_BGA package in Figure 39 are shown in millimeters.

- 1. ALL DIMENSIONS ARE IN MILLIMETERS.
- 2. COMPLIANT TO JEDEC REGISTERED OUTLINE MO-205, VARIATION AM, WITH THE EXCEPTION OF BALL DIAMETER.
- 3. CENTER DIMENSIONS ARE NOMINAL.

Figure 39. 400-Ball, 17 mm \times 17 mm CSP_BGA (Chip Scale Package Ball Grid Array) (BC-400)

Dimensions for the 360-ball PBGA 27 mm \times 27 mm package in Figure 40 are shown in millimeters.

(B-360-1) Dimensions shown in millimeters 27.00 SQ - 6.75 BSC A1 BALL PAD CORNER 24.00 SQ 23.80 25.00 BSC SQ 1.00 BSC TOP VIEW 1.00 REF **BOTTOM VIEW** $\frac{2.40}{2.28} \\ \hline 2.13$ 1.22 **DETAIL A** 1.17 0.66 1.12 0.61 COPLANARITY 0.20 MAX 0.50 NOM 0.45 MIN 0.70 SEATING PLANE 0.60 0.50 BALL DIAMETER COMPLIANT TO JEDEC STANDARDS MS-034-AAL-1

SURFACE MOUNT DESIGN

Table 59 is provided as an aid to PCB design. For industrystandard design recommendations, refer to IPC-7351, *Generic Requirements for Surface Mount Design and Land Pattern Standard.*

Table 59. BGA Data for Use with Surface Mount Design

| Package | Ball Attach Type | Solder Mask Opening | Ball Pad Size |
|--|----------------------|---------------------|------------------|
| 400-Ball CSP_BGA (Chip Scale Package Ball Grid Array) BC-400 | Solder Mask Defined | 0.40 mm diameter | 0.50 mm diameter |
| 360-Ball PBGA (B-360-1) | Soldier Mask Defined | 0.43 mm diameter | 0.56 mm diameter |

ORDERING GUIDE

Part numbers that include "Z" are RoHS Compliant.

| Part Number | Temperature | SpeedGrade | Operating Voltage (Nominal) | Package Description | Package Option |
|--------------------|-----------------|------------|-------------------------------------|---------------------|----------------|
| | Range (Ambient) | (Max) | | | |
| ADSP-BF549BBCZ-ENG | -40°C to 85°C | 533 MHZ | 1.25 V internal, 2.5 V or 3.3 V I/O | 400-Ball CSP_BGA | BC-400 |
| ADSP-BF549BBZ-ENG | -40°C to 85°C | 533 MHZ | 1.25 V internal, 2.5 V or 3.3 V I/O | 360-Ball PBGA | B-360 |
| ADSP-BF548BBCZ-5X | -40°C to 85°C | 533 MHZ | 1.25 V internal, 2.5 V or 3.3 V I/O | 400-Ball CSP_BGA | BC-400 |
| ADSP-BF547BBCZ-5X | -40°C to 85°C | 533 MHZ | 1.25 V internal, 2.5 V or 3.3 V I/O | 400-Ball CSP_BGA | BC-400 |
| ADSP-BF544BBCZ-5X | -40°C to 85°C | 533 MHZ | 1.25 V internal, 2.5 V or 3.3 V I/O | 400-Ball CSP_BGA | BC-400 |
| ADSP-BF542BBCZ-5X | -40°C to 85°C | 533 MHZ | 1.25 V internal, 2.5 V or 3.3 V I/O | 400-Ball CSP_BGA | BC-400 |
