Features

- 80C51 Core Architecture
- 256 Bytes of On-chip RAM
- 256 Bytes of On-chip XRAM
- 16K Bytes of On-chip Flash Memory
  - Data Retention: 10 Years at 85°C
  - Erase/Write Cycle: 100K
- Boot Code Section with Independent Lock Bits
- 2K Bytes of On-chip Flash for Bootloader
- In-System Programming by On-Chip Boot Program (CAN, UART) and IAP Capability
- 2K Bytes of On-chip EEPROM
  - Erase/Write Cycle: 100K
- 14-sources 4-level Interrupts
- Three 16-bit Timers/Counters
- Full Duplex UART Compatible 80C51
- Maximum Crystal Frequency 40 MHz. In X2 Mode, 20 MHz (CPU Core, 40 MHz)
- Three or Four Ports: 16 or 20 Digital I/O Lines
- Two-channel 16-bit PCA
  - PWM (8-bit)
  - High-speed Output
  - Timer and Edge Capture
- Double Data Pointer
- 21-bit Watchdog Timer (7 Programmable bits)
- A 10-bit Resolution Analog-to-Digital Converter (ADC) with 8 Multiplexed Inputs
- Full CAN Controller
  - Fully Compliant with CAN rev.# 2.0A and 2.0B
  - Optimized Structure for Communication Management (Via SFR)
  - 4 Independent Message Objects
    - -Each Message Object Programmable on Transmission or Reception
    - -Individual Tag and Mask Filters up to 29-bit Identifier/Channel
    - -8-byte Cyclic Data Register (FIFO)/Message Object
    - -16-bit Status and Control Register/Message Object
    - -16-bit Time-Stamping Register/Message Object
    - -CAN Specification 2.0 Part A or 2.0 Part B Programmable for Each Message Object
    - -Access to Message Object Control and Data Registers Via SFR
    - -Programmable Reception Buffer Length up to 4 Message Objects
    - -Priority Management of Reception of Hits on Several Message Objects Simultaneously (Basic CAN Feature)
    - -Priority Management for Transmission
    - -Message Object Overrun Interrupt
  - Supports
    - -Time Triggered Communication
    - -Autobaud and Listening Mode
    - -Programmable Automatic Reply Mode
- 1-Mbit/s Maximum Transfer Rate at 8 MHz[1] Crystal Frequency In X2 Mode
- Readable Error Counters
- Programmable Link to On-chip Timer for Time Stamping and Network Synchronization
- Independent Baud Rate Prescaler
- Data, Remote, Error and Overload Frame Handling
- Power-saving Modes
  - Idle Mode
  - Power-down Mode
- Power Supply: 3 Volts to 5.5 Volts
- Temperature Range: Industrial (-40° to +85°C)
- Packages: SOIC28, SOIC24, PLCC28, VQFP32

Note: 1. At BRP = 1 sampling point will be fixed.

Enhanced 8-bit Microcontroller with CAN Controller and Flash

T89C51CC02
AT89C51CC02

Rev. 4126J–CAN–05/06

Description

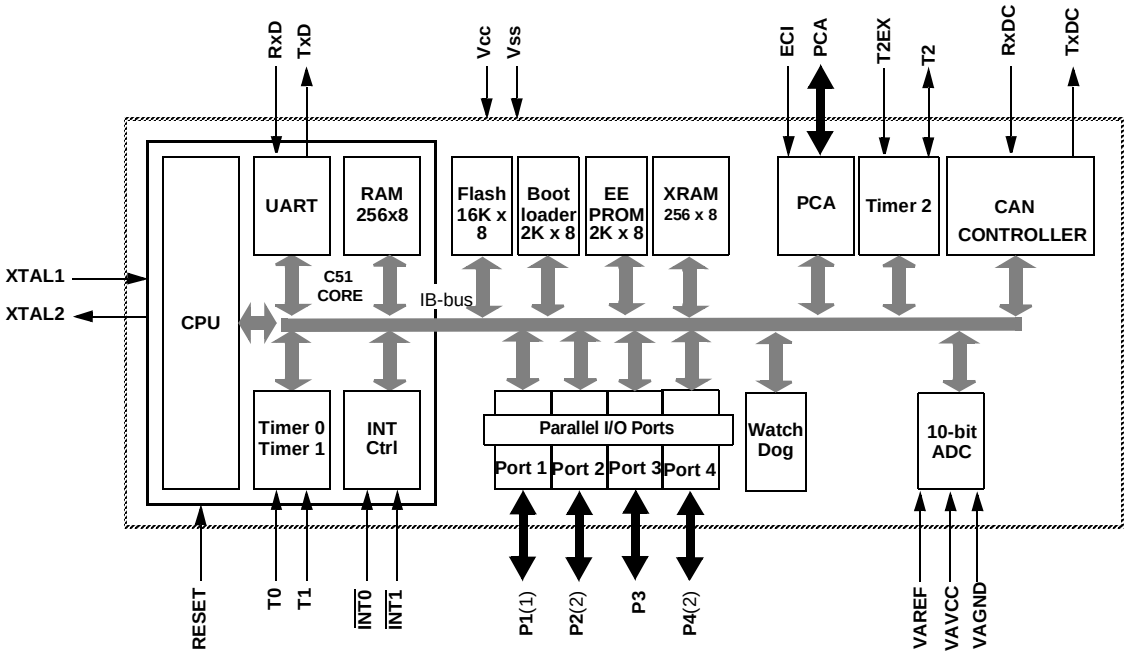
Part of the CANary™ family of 8-bit microcontrollers dedicated to CAN network applications, the T89C51CC02 is a low-pin count 8-bit Flash microcontroller.

In X2 Mode a maximum external clock rate of 20 MHz reaches a 300 ns cycle time.

Besides the full CAN controller T89C51CC02 provides 16K Bytes of Flash memory including In-System Programming (ISP), 2K Bytes Boot Flash Memory, 2K Bytes EEPROM and 512 Bytes RAM.

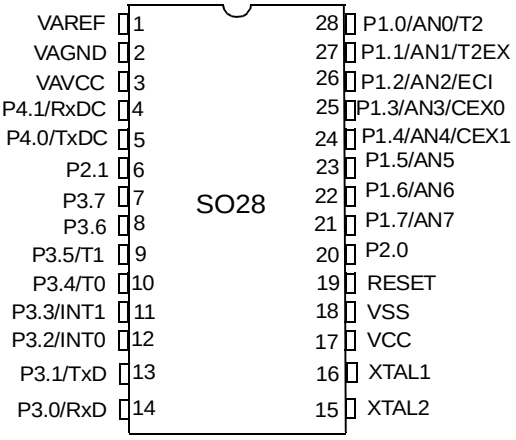
Special attention is payed to the reduction of the electro-magnetic emission of T89C51CC02.

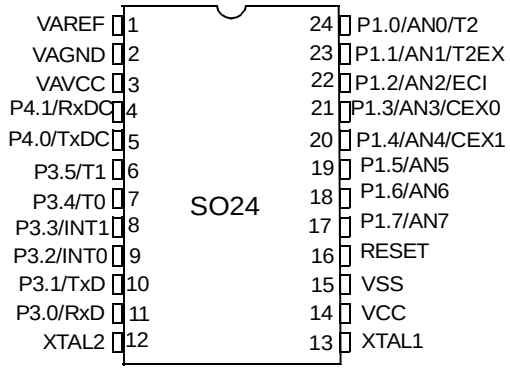
Block Diagram

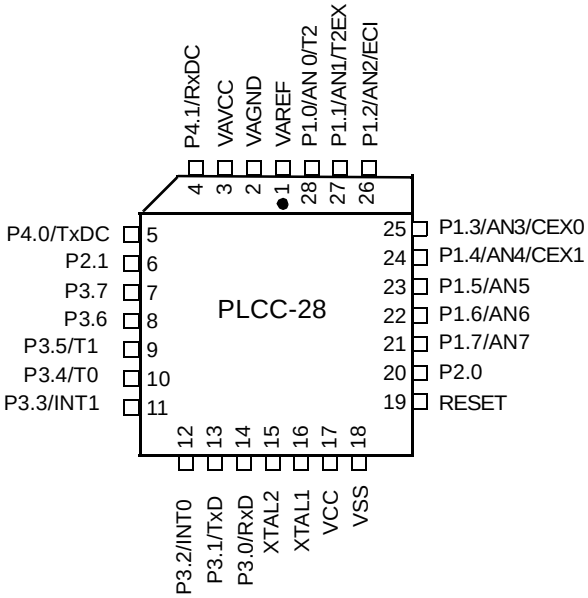


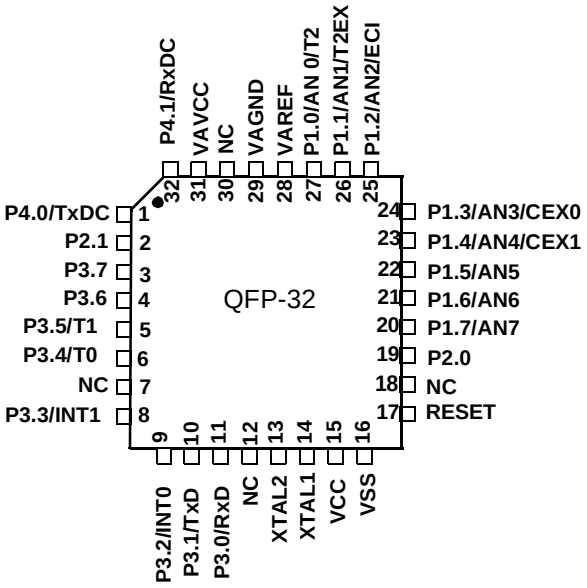
Note: 1. 8 analog Inputs/8 Digital I/O.
2. 2-bit I/O Port.

Pin Configurations









Pin Description

Pin Name	Type	Description
VSS	GND	Circuit ground
VCC		**Supply Voltage**
VAREF		Reference Voltage for ADC (input)
VAVCC		Supply Voltage for ADC
VAGND		Reference Ground for ADC (internaly connected with the VSS)
P1.0:7	I/O	**Port 1:** Is an 8-bit bi-directional I/O port with internal pull-ups. Port 1 pins can be used for digital input/output or as analog inputs for the Analog Digital Converter (ADC). Port 1 pins that have 1's written to them are pulled high by the internal pull-up transistors and can be used as inputs in this state. As inputs, Port 1 pins that are being pulled low externally will be the source of current (I_{IL}, See section 'Electrical Characteristic') because of the internal pull-ups. Port 1 pins are assigned to be used as analog inputs via the ADCCF register (in this case the internal pull-ups are disconnected). As a secondary digital function, port 1 contains the Timer 2 external trigger and clock input; the PCA external clock input and the PCA module I/O. P1.0/AN0/T2 Analog input channel 0, External clock input for Timer/counter2. P1.1/AN1/T2EX Analog input channel 1, Trigger input for Timer/counter2. P1.2/AN2/ECI Analog input channel 2, PCA external clock input. P1.3/AN3/CEX0 Analog input channel 3, PCA module 0 Entry of input/PWM output. P1.4/AN4/CEX1 Analog input channel 4, PCA module 1 Entry of input/PWM output. P1.5/AN5 Analog input channel 5, P1.6/AN6 Analog input channel 6, P1.7/AN7 Analog input channel 7, It can drive CMOS inputs without external pull-ups.
P2.0:1	I/O	**Port 2:** Is an 2-bit bi-directional I/O port with internal pull-ups. Port 2 pins that have 1's written to them are pulled high by the internal pull-ups and can be used as inputs in this state. As inputs, Port 2 pins that are being pulled low externally will be a source of current (IIL, on the datasheet) because of the internal pull-ups. In the T89C51CC02 Port 2 can sink or source 5mA. It can drive CMOS inputs without external pull-ups.

Pin Name	Type	Description
P3.0:7	I/O	**Port 3:** Is an 8-bit bi-directional I/O port with internal pull-ups. Port 3 pins that have 1's written to them are pulled high by the internal pull-up transistors and can be used as inputs in this state. As inputs, Port 3 pins that are being pulled low externally will be a source of current (I_{IL}, See section 'Electrical Characteristic') because of the internal pull-ups. The output latch corresponding to a secondary function must be programmed to one for that function to operate (except for TxD and $\overline{WR}$). The secondary functions are assigned to the pins of port 3 as follows: P3.0/RxD: Receiver data input (asynchronous) or data input/output (synchronous) of the serial interface P3.1/TxD: Transmitter data output (asynchronous) or clock output (synchronous) of the serial interface P3.2/$\overline{INT0}$: External interrupt 0 input/timer 0 gate control input P3.3/$\overline{INT1}$: External interrupt 1 input/timer 1 gate control input P3.4/T0: Timer 0 counter input P3.5/T1: Timer 1 counter input P3.6: Regular I/O port pin P3.7: Regular I/O port pin
P4.0:1	I/O	**Port 4:** Is an 2-bit bi-directional I/O port with internal pull-ups. Port 4 pins that have 1's written to them are pulled high by the internal pull-ups and can be used as inputs in this state. As inputs, Port 4 pins that are being pulled low externally will be a source of current (IIL, on the datasheet) because of the internal pull-up transistor. The output latch corresponding to a secondary function RxDC must be programmed to one for that function to operate. The secondary functions are assigned to the two pins of port 4 as follows: P4.0/TxDC: Transmitter output of CAN controller P4.1/RxDC: Receiver input of CAN controller. It can drive CMOS inputs without external pull-ups.
RESET	I/O	**Reset:** A high level on this pin during two machine cycles while the oscillator is running resets the device. An internal pull-down resistor to VSS permits power-on reset using only an external capacitor to VCC.
XTAL1	I	**XTAL1:** Input of the inverting oscillator amplifier and input of the internal clock generator circuits. To drive the device from an external clock source, XTAL1 should be driven, while XTAL2 is left unconnected. To operate above a frequency of 16 MHz, a duty cycle of 50% should be maintained.
XTAL2	O	**XTAL2:** Output from the inverting oscillator amplifier.

I/O Configurations

Each Port SFR operates via type-D latches, as illustrated in Figure 1 for Ports 3 and 4. A CPU 'write to latch' signal initiates transfer of internal bus data into the type-D latch. A CPU 'read latch' signal transfers the latched Q output onto the internal bus. Similarly, a 'read pin' signal transfers the logical level of the Port pin. Some Port data instructions activate the 'read latch' signal while others activate the 'read pin' signal. Latch instructions are referred to as Read-Modify-Write instructions. Each I/O line may be independently programmed as input or output.

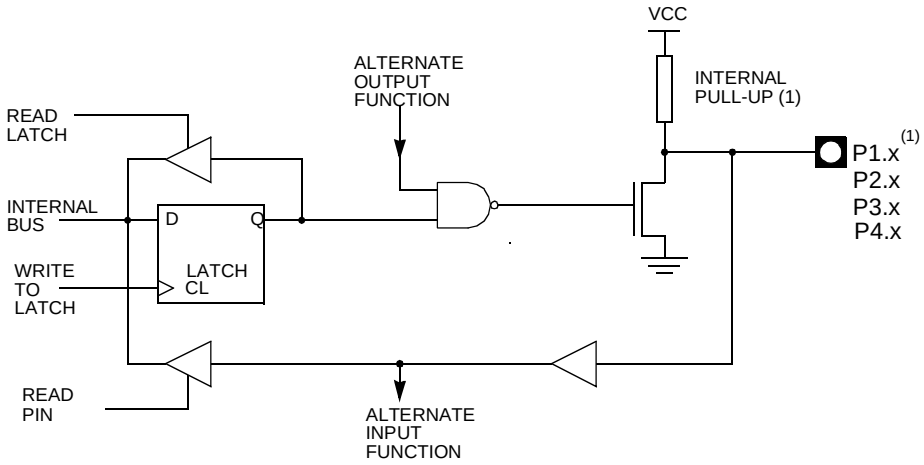
Port Structure

Figure 1 shows the structure of Ports, which have internal pull-ups. An external source can pull the pin low. Each Port pin can be configured either for general-purpose I/O or for its alternate input output function.

To use a pin for general-purpose output, set or clear the corresponding bit in the Px register (x = 1 to 4). To use a pin for general-purpose input, set the bit in the Px register. This turns off the output FET drive.

To configure a pin for its alternate function, set the bit in the Px register. When the latch is set, the 'alternate output function' signal controls the output level (See Figure 1). The operation of Ports is discussed further in 'Quasi-Bi-directional Port Operation' paragraph.

Figure 1. Ports Structure



Note: 1. The internal pull-up can be disabled on P1 when analog function is selected.

Read-Modify-Write Instructions

Some instructions read the latch data rather than the pin data. The latch based instructions read the data, modify the data and then rewrite the latch. These are called 'Read-Modify-Write' instructions. Below is a complete list of these special instructions (See Table 1). When the destination operand is a Port or a Port bit, these instructions read the latch rather than the pin:

Table 1. Read/Modify/Write Instructions

Instruction	Description	Example
ANL	Logical AND	ANL P1, A
ORL	Logical OR	ORL P2, A
XRL	Logical EX-OR	XRL P3, A
JBC	Jump if bit = 1 and clear bit	JBC P1.1, LABEL
CPL	Complement bit	CPL P3.0
INC	Increment	INC P2
DEC	Decrement	DEC P2
DJNZ	Decrement and jump if not zero	DJNZ P3, LABEL
MOV Px.y, C	Move carry bit to bit y of Port x	MOV P1.5, C
CLR Px.y	Clear bit y of Port x	CLR P2.4
SET Px.y	Set bit y of Port x	SET P3.3

It is not obvious that the last three instructions in this list are Read-Modify-Write instructions. These instructions read the port (all 8 bits), modify the specifically addressed bit and write the new byte back to the latch. These Read-Modify-Write instructions are directed to the latch rather than the pin in order to avoid possible misinterpretation of voltage (and therefore, logic) levels at the pin. For example, a Port bit used to drive the base of an external bipolar transistor cannot rise above the transistor's base-emitter junction voltage (a value lower than VIL). With a logic one written to the bit, attempts by the CPU to read the Port at the pin are misinterpreted as logic zero. A read of the latch rather than the pins returns the correct logic one value.

Quasi Bi-directional Port Operation

Port 1, Port 3 and Port 4 have fixed internal pull-ups and are referred to as 'quasi-bidirectional' Ports. When configured as an input, the pin impedance appears as logic one and sources current in response to an external logic zero condition. Resets write logic one to all Port latches. If logical zero is subsequently written to a Port latch, it can be returned to input conditions by a logic one written to the latch.

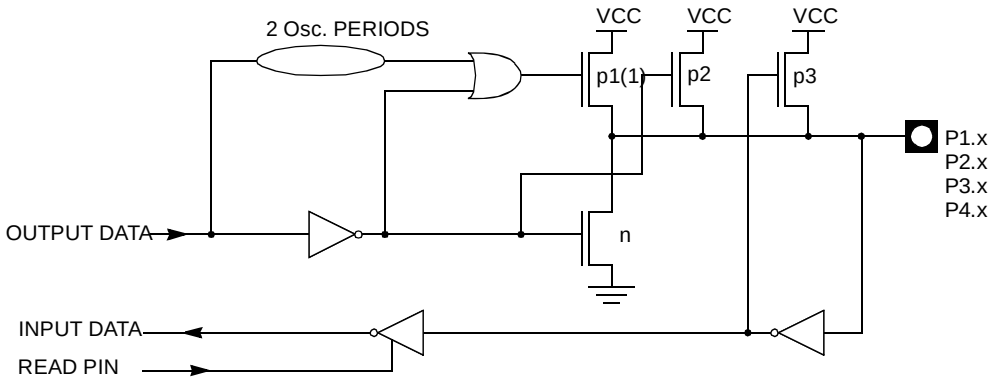
Note: Port latch values change near the end of Read-Modify-Write insruction cycles. Output buffers (and therefore the pin state) are updated early in the instruction after Read-Modify-Write instruction cycle.

Logical zero-to-one transitions in Port 1, Port 3 and Port 4 use an additional pull-up (p1) to aid this logic transition See Figure 2. This increases switch speed. This extra pull-up sources 100 times normal internal circuit current during 2 oscillator clock periods. The internal pull-ups are field-effect transistors rather than linear resistors. Pull-ups consist of three p-channel FET (pFET) devices. A pFET is on when the gate senses logic zero and off when the gate senses logic one. pFET #1 is turned on for two oscillator periods immediately after a zero-to-one transition in the Port latch. A logic one at the Port pin turns on pFET #3 (a weak pull-up) through the inverter. This inverter and pFET pair form a latch to drive logic one. pFET #2 is a very weak pull-up switched on whenever the

associated nFET is switched off. This is traditional CMOS switch convention. Current strengths are 1/10 that of pFET #3.

Note: During Reset, pFET#1 is not avtivated. During Reset, only the weak pFET#3 pull up the pin.

Figure 2. Internal Pull-up Configurations



SFR Mapping

Tables 3 through Table 11 show the Special Function Registers (SFRs) of the T89C51CC02.

Table 2. C51 Core SFRs

Reserved

Notes: 1. These registers are bit-addressable.
Sixteen addresses in the SFR space are both byte-addressable and bit-addressable. The bit-addressable SFRs are those whose address ends in 0 and 8. The bit addresses, in this area, are 0x80 through to 0xFF.
2. AUXR1 bit ENBOOT is initialized with the content of the BLJB bit inverted.

Clock

The T89C51CC02 core needs only 6 clock periods per machine cycle. This feature, called “X2”, provides the following advantages:

- Divides frequency crystals by 2 (cheaper crystals) while keeping the same CPU power.
- Saves power consumption while keeping the same CPU power (oscillator power saving).
- Saves power consumption by dividing dynamic operating frequency by 2 in operating and idle modes.
- Increases CPU power by 2 while keeping the same crystal frequency.

In order to keep the original C51 compatibility, a divider-by-2 is inserted between the XTAL1 signal and the main clock input of the core (phase generator). This divider may be disabled by the software.

An extra feature is available to start after Reset in the X2 Mode. This feature can be enabled by a bit X2B in the Hardware Security Byte. This bit is described in the section ’In-System Programming’.

Description

The X2 bit in the CKCON register (See Table 12) allows switching from 12 clock cycles per instruction to 6 clock cycles and vice versa. At reset, the standard speed is activated (STD mode).

Setting this bit activates the X2 feature (X2 Mode) for the CPU Clock only (See Figure 3).

The Timers 0, 1 and 2, Uart, PCA, watchdog or CAN switch in X2 Mode only if the corresponding bit is cleared in the CKCON register.

The clock for the whole circuit and peripheral is first divided by two before being used by the CPU core and peripherals. This allows any cyclic ratio to be accepted on the XTAL1 input. In X2 Mode, as this divider is bypassed, the signals on XTAL1 must have a cyclic ratio between 40 to 60%. Figure 3. shows the clock generation block diagram. The X2 bit is validated on the XTAL1 ÷ 2 rising edge to avoid glitches when switching from the X2 to the STD mode. Figure 4 shows the mode switching waveforms.

Figure 3. Clock CPU Generation Diagram

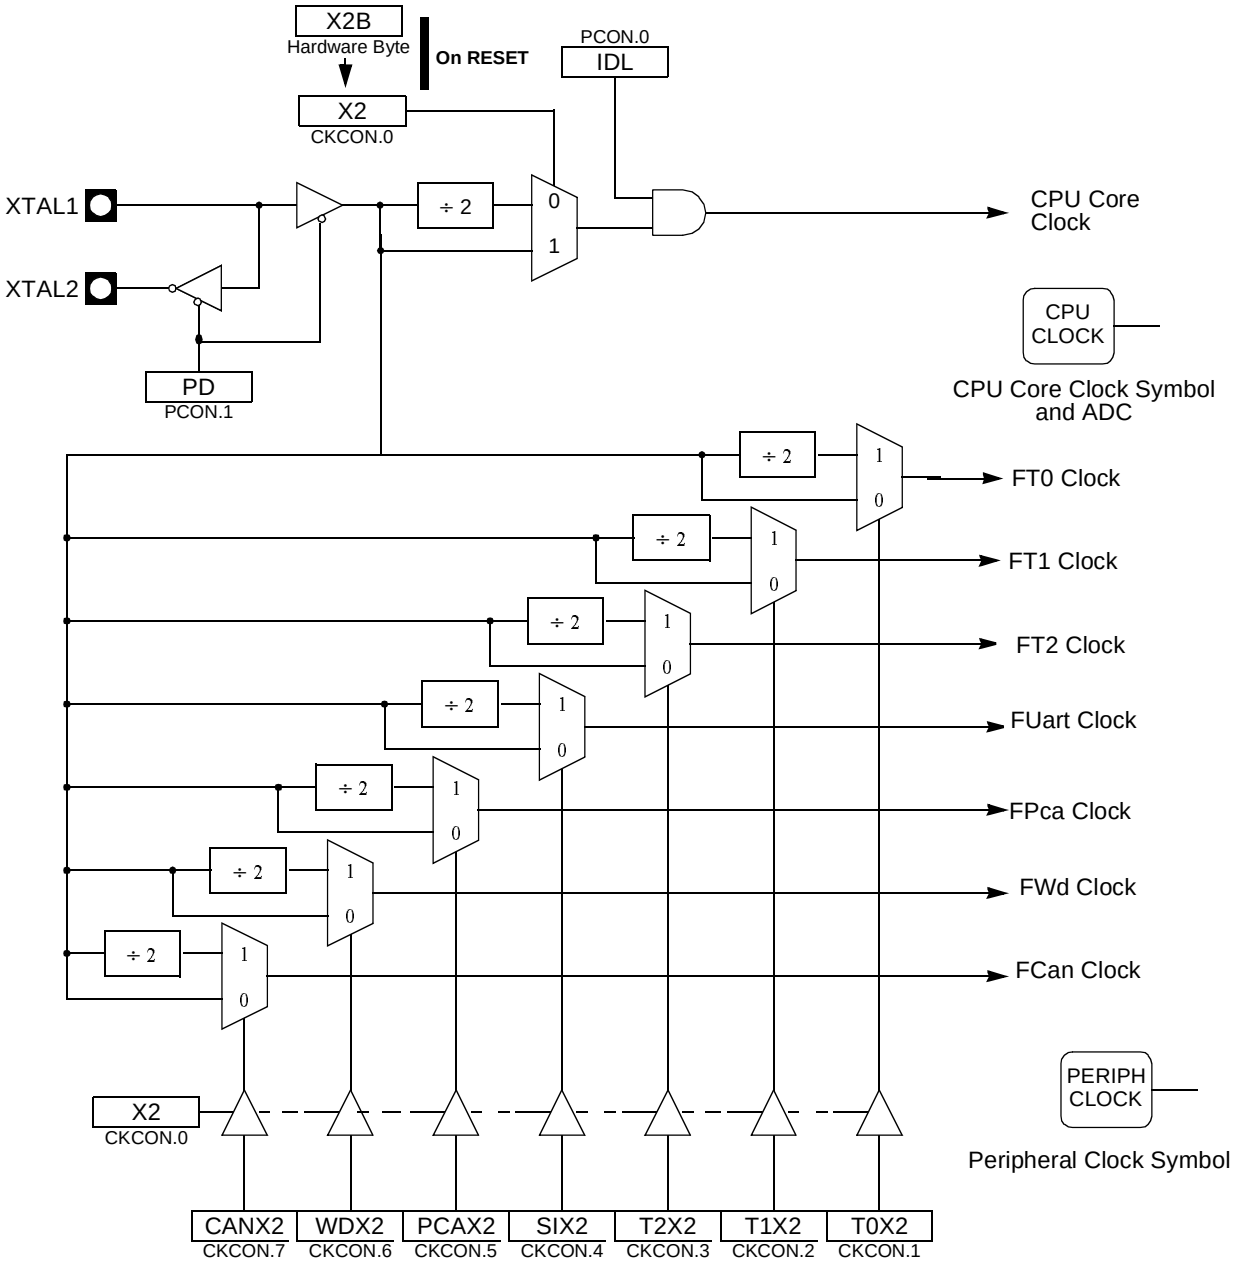

Figure 4. Mode Switching Waveforms[1]

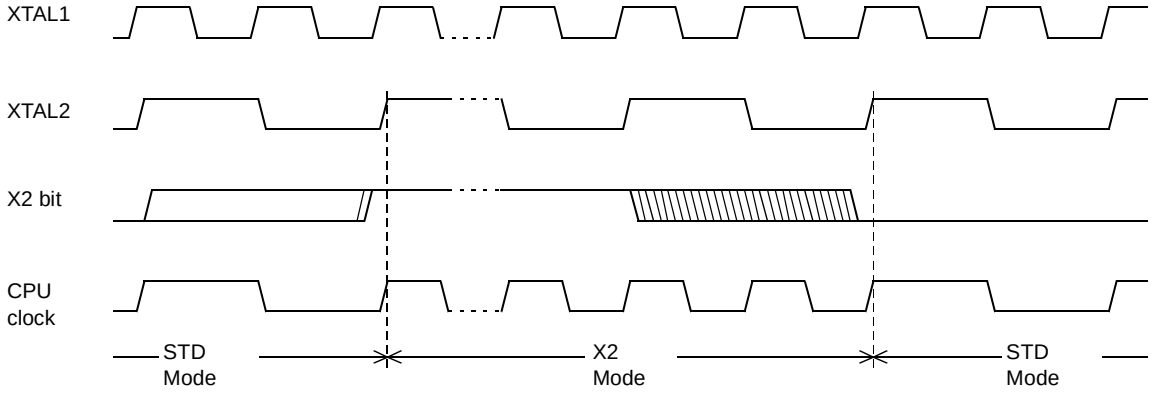

Note: 1. In order to prevent any incorrect operation while operating in the X2 Mode, users must be aware that all peripherals using the clock frequency as a time reference (UART, timers...) will have their time reference divided by 2. For example, a free running timer generating an interrupt every 20 ms will then generate an interrupt every 10 ms. A UART with a 4800 baud rate will have a 9600 baud rate.

Register

Table 12. CKCON Register

CKCON (S:8Fh)

Clock Control Register

7	6	5	4	3	2	1	0
CANX2	WDX2	PCAX2	SIX2	T2X2	T1X2	T0X2	X2

Bit Number	Bit Mnemonic	Description
7	CANX2	**CAN Clock** (1) Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
6	WDX2	**Watchdog Clock** (1) Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
5	PCAX2	**Programmable Counter Array Clock** (1) Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
4	SIX2	**Enhanced UART clock (MODE 0 and 2)** (1) Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
3	T2X2	**Timer 2 Clock** (1) Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
2	T1X2	**Timer 1 Clock** (1) Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
1	T0X2	**Timer 0 Clock** (1) Clear to select 6 clock periods per peripheral clock cycle. Set to select 12 clock periods per peripheral clock cycle.
0	X2	**CPU Clock** Clear to select 12 clock periods per machine cycle (STD mode) for CPU and all the peripherals. Set to select 6 clock periods per machine cycle (X2 Mode) and to enable the individual peripherals 'X2' bits.

Note: 1. This control bit is validated when the CPU clock bit X2 is set; when X2 is low, this bit has no effect.

Reset Value = 0000 0000b

Power Management

Two power reduction modes are implemented in the A/T89C51CC02: the Idle mode and the Power-down mode. These modes are detailed in the following sections. In addition to these power reduction modes, the clocks of the core and peripherals can be dynamically divided by 2 using the X2 Mode detailed in Section “Clock”.

Reset Pin

In order to start-up (cold reset) or to restart (warm reset) properly the microcontroller, a high level has to be applied on the RST pin. A bad level leads to a wrong initialisation of the internal registers like SFRs, PC, etc. and to unpredictable behavior of the microcontroller. A warm reset can be applied either directly on the RST pin or indirectly by an internal reset source such as a watchdog, PCA, timer, etc.

At Power-up (cold reset)

Two conditions are required before enabling a CPU start-up:

- VDD must reach the specified VDD range,
- The level on xtal1 input must be outside the specification (VIH, VIL).

If one of these two conditions are not met, the microcontroller does not start correctly and can execute an instruction fetch from anywhere in the program space. An active level applied on the RST pin must be maintained until both of the above conditions are met. A reset is active when the level VIH1 is reached and when the pulse width covers the period of time where VDD and the oscillator are not stabilized. Two parameters have to be taken into account to determine the reset pulse width:

- VDD rise time (vddrst),
- Oscillator startup time (oscrst).

To determine the capacitor the highest value of these two parameters has to be chosen. The reset circuitry is shown in Figure 5.

Figure 5. Reset Circuitry

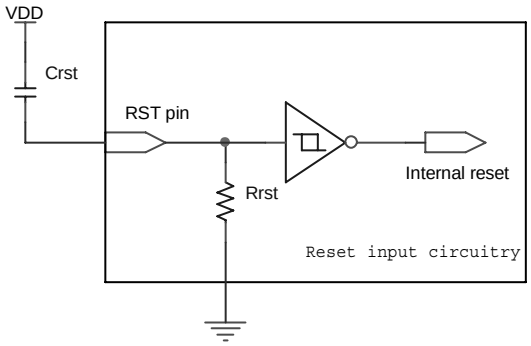

Table 13 and Table 14 give some typical examples for three values of VDD rise times, two values of oscillator start-up time and two pull-down resistor values.

Table 13. Minimum Reset Capacitor for a 50K Pull-down Resistor

oscrst/vddrst	1ms	10ms	100ms
5ms	820nF	1.2µF	12µF
20ms	2.7µF	3.9µF	12µF

Table 14. Minimum Reset Capacitor for a 15k Pull-down Resistor

oscrst/vddrst	1ms	10ms	100ms
5ms	2.7µF	4.7µF	47µF
20ms	10µF	15µF	47µF

Note: These values assume VDD starts from 0v to the nominal value. If the time between two on/off sequences is too fast, the power-supply decoupling capacitors may not be fully discharged, leading to a bad reset sequence.

During a Normal Operation (Warm Reset)

Reset pin must be maintained for at least 2 machine cycles (24 oscillator clock periods) to apply a reset sequence during normal operation. The number of clock periods is mode independent (X2 or X1).

Watchdog Reset

A 1K resistor must be added in series with the capacitor to allow the use of watchdog reset pulse output on the RST pin or when an external power-supply supervisor is used. Figure 6 shows the reset circuitry when a capacitor is used.

Figure 6. Reset Circuitry for a Watchdog Configuration

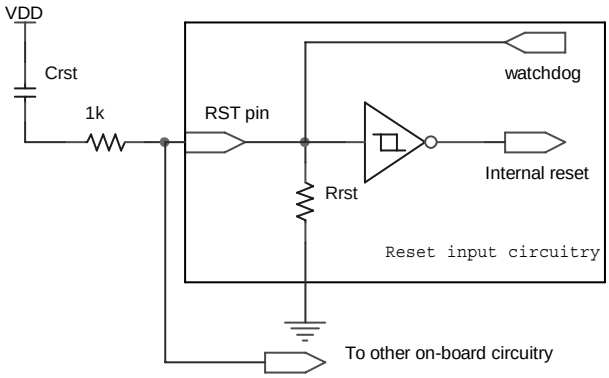

Figure 7 shows the reset circuitry when an external reset circuit is used.

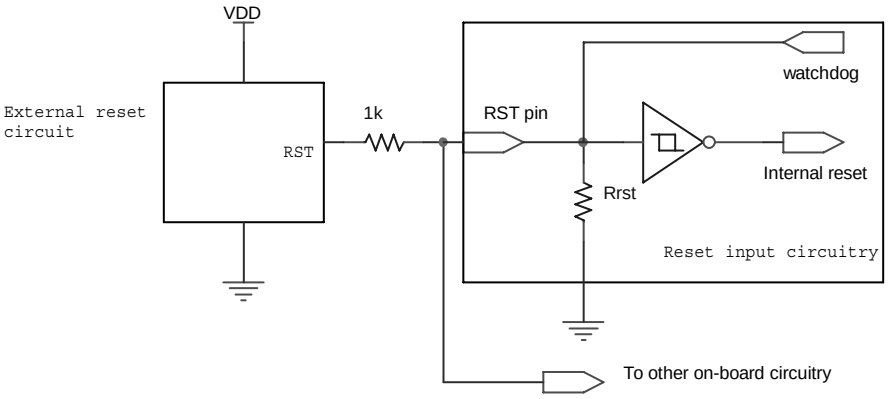
Figure 7. Reset Circuitry Example Using an External Reset Circuit



Reset Recommendation to Prevent Flash Corruption

When a Flash program memory is embedded on-chip, it is strongly recommended to use an external reset chip (brown out device) to apply a reset (Figure 7). It prevents system malfunction during periods of insufficient power-supply voltage (power-supply failure, power supply switched off, etc.).

Idle Mode

Idle mode is a power reduction mode that reduces the power consumption. In this mode, program execution halts. Idle mode freezes the clock to the CPU at known states while the peripherals continue to be clocked. The CPU status before entering Idle mode is preserved, i.e., the program counter and program status word register retain their data for the duration of Idle mode. The contents of the SFRs and RAM are also retained. The status of the Port pins during Idle mode is detailed in Table 15.

Entering Idle Mode

To enter Idle mode, set the IDL bit in PCON register (See Table 16). The A/T89C51CC02 enters Idle mode upon execution of the instruction that sets IDL bit. The instruction that sets IDL bit is the last instruction executed.

Note: If IDL bit and PD bit are set simultaneously, the A/T89C51CC02 enters Power-down mode. Then it does not go in Idle mode when exiting Power-down mode.

Exiting Idle Mode

There are two ways to exit Idle mode:

1. Generate an enabled interrupt.

   Hardware clears IDL bit in PCON register which restores the clock to the CPU. Execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Idle mode. The general purpose flags (GF1 and GF0 in PCON register) may be used to indicate whether an interrupt occurred during normal operation or during Idle mode. When Idle mode is exited by an interrupt, the interrupt service routine may examine GF1 and GF0.

2. Generate a reset.

   A logic high on the RST pin clears IDL bit in PCON register directly and asynchronously. This restores the clock to the CPU. Program execution momentarily resumes with the instruction immediately following the instruction that activated the Idle mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the A/T89C51CC02 and vectors the CPU to address C:0000h.

Notes:
1. During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port pins, the instruction immediately following the instruction that activated Idle mode should not write to a Port pin or to the external RAM.
2. If Idle mode is invoked by ADC Idle, the ADC conversion completion will exit Idle.

Power-down Mode

The Power-down mode places the A/T89C51CC02 in a very low power state. Power-down mode stops the oscillator, freezes all clock at known states. The CPU status prior to entering Power-down mode is preserved, i.e., the program counter, program status word register retain their data for the duration of Power-down mode. In addition, the SFRs and RAM contents are preserved. The status of the Port pins during Power-down mode is detailed in Table 15.

Entering Power-down Mode

To enter Power-down mode, set PD bit in PCON register. The A/T89C51CC02 enters the Power-down mode upon execution of the instruction that sets PD bit. The instruction that sets PD bit is the last instruction executed.

Exiting Power-down Mode

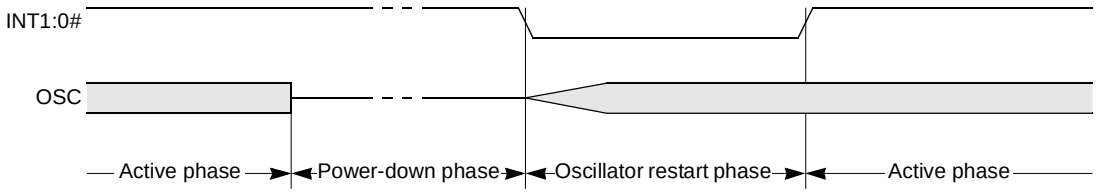
Note: If V_{DD} was reduced during the Power-down mode, do not exit Power-down mode until V_{DD} is restored to the normal operating level.

There are two ways to exit the Power-down mode:

1. Generate an enabled external interrupt.
   – The A/T89C51CC02 provides capability to exit from Power-down using INT0#, INT1#.
   Hardware clears PD bit in PCON register which starts the oscillator and restores the clocks to the CPU and peripherals. Using INTx# input, execution resumes when the input is released (See Figure 8). Execution resumes with the interrupt service routine. Upon completion of the interrupt service routine, program execution resumes with the instruction immediately following the instruction that activated Power-down mode.

Notes:
1. The external interrupt used to exit Power-down mode must be configured as level sensitive (INT0# and INT1#) and must be assigned the highest priority. In addition, the duration of the interrupt must be long enough to allow the oscillator to stabilize. The execution will only resume when the interrupt is deasserted.
2. Exit from power-down by external interrupt does not affect the SFRs nor the internal RAM content.

Figure 8. Power-down Exit Waveform Using INT1:0#



2. Generate a reset.
   – A logic high on the RST pin clears PD bit in PCON register directly and asynchronously. This starts the oscillator and restores the clock to the CPU and peripherals. Program execution momentarily resumes with the instruction immediately following the instruction that activated Power-down mode and may continue for a number of clock cycles before the internal reset algorithm takes control. Reset initializes the A/T89C51CC02 and vectors the CPU to address 0000h.

Notes:
1. During the time that execution resumes, the internal RAM cannot be accessed; however, it is possible for the Port pins to be accessed. To avoid unexpected outputs at the Port pins, the instruction immediately following the instruction that activated the Power-down mode should not write to a Port pin or to the external RAM.
2. Exit from power-down by reset redefines all the SFRs, but does not affect the internal RAM content.

Table 15. Pin Conditions in Special Operating Modes

Mode	Port 1	Port 2	Port 3	Port 4
Reset	High	High	High	High
Idle (internal code)	Data	Data	Data	Data
Idle (external code)	Data	Data	Data	Data
Power-Down(internal code)	Data	Data	Data	Data
Power-Down (external code)	Data	Data	Data	Data

Not bit addressable

Data Memory

The T89C51CC02 provides data memory access in two different spaces:

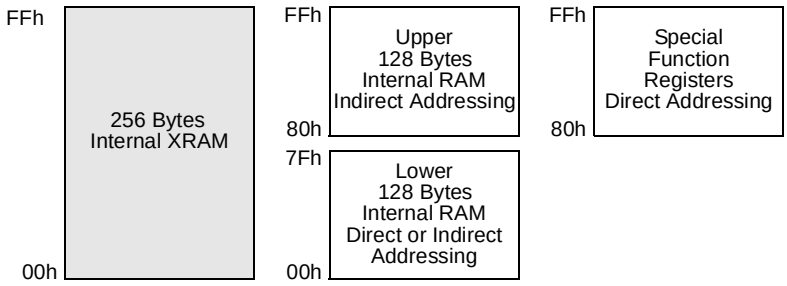
The internal space mapped in three separate segments:

- The lower 128 Bytes RAM segment.
- The upper 128 Bytes RAM segment.
- The expanded 256 Bytes RAM segment (XRAM).

A fourth internal segment is available but dedicated to Special Function Registers, SFRs, (addresses 80h to FFh) accessible by direct addressing mode.

Figure 9 shows the internal data memory spaces organization.

Figure 9. Internal memory - RAM



Internal Space

Lower 128 Bytes RAM

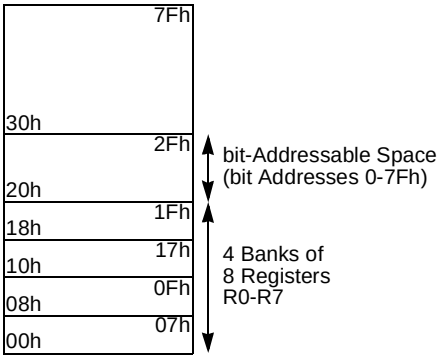
The lower 128 Bytes of RAM (See Figure 10) are accessible from address 00h to 7Fh using direct or indirect addressing modes. The lowest 32 Bytes are grouped into 4 banks of 8 registers (R0 to R7). Two bits RS0 and RS1 in PSW register (See Table 18) select which bank is in use according to Table 17. This allows more efficient use of code space, since register instructions are shorter than instructions that use direct addressing, and can be used for context switching in interrupt service routines.

Table 17. Register Bank Selection

RS1	RS0	Description
0	0	Register bank 0 from 00h to 07h
0	1	Register bank 0 from 08h to 0Fh
1	0	Register bank 0 from 10h to 17h
1	1	Register bank 0 from 18h to 1Fh

The next 16 Bytes above the register banks form a block of bit-addressable memory space. The C51 instruction set includes a wide selection of singlebit instructions, and the 128 bits in this area can be directly addressed by these instructions. The bit addresses in this area are 00h to 7Fh.

Figure 10. Lower 128 Bytes Internal RAM Organization



Upper 128 Bytes RAM

The upper 128 Bytes of RAM are accessible from address 80h to FFh using only indirect addressing mode.

Expanded RAM

The on-chip 256 Bytes of expanded RAM (XRAM) are accessible from address 0000h to 00FFh using indirect addressing mode through MOVX instructions. In this address range.

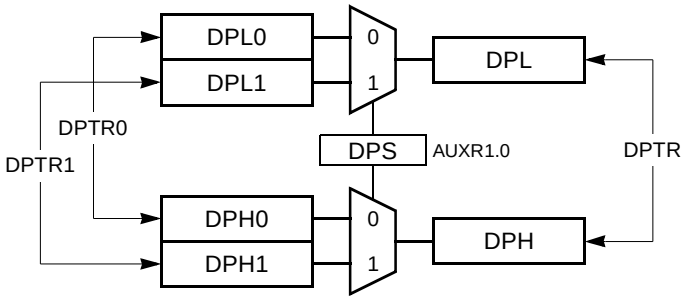
Note: Lower 128 Bytes RAM, Upper 128 Bytes RAM, and expanded RAM are made of volatile memory cells. This means that the RAM content is indeterminate after power-up and must then be initialized properly.

Dual Data Pointer

Description

The T89C51CC02 implements a second data pointer for speeding up code execution and reducing code size in case of intensive usage of external memory accesses.
DPTR0 and DPTR1 are Seen by the CPU as DPTR and are accessed using the SFR addresses 83h and 84h that are the DPH and DPL addresses. The DPS bit in AUXR1 register (See Figure 19) is used to select whether DPTR is the data pointer 0 or the data pointer 1 (See Figure 11).

Figure 11. Dual Data Pointer Implementation



Application

Software can take advantage of the additional data pointers to both increase speed and reduce code size, for example, block operations (copy, compare…) are well served by using one data pointer as a “source” pointer and the other one as a “destination” pointer. Hereafter is an example of block move implementation using the two pointers and coded in assembler. The latest C compiler takes also advantage of this feature by providing enhanced algorithm libraries.
The INC instruction is a short (2 Bytes) and fast (6 machine cycle) way to manipulate the DPS bit in the AUXR1 register. However, note that the INC instruction does not directly force the DPS bit to a particular state, but simply toggles it. In simple routines, such as the block move example, only the fact that DPS is toggled in the proper sequence matters, not its actual value. In other words, the block move routine works the same whether DPS is 0 or 1 on entry.

```
; ASCII block move using dual data pointers
; Modifies DPTR0, DPTR1, A and PSW
; Ends when encountering NULL character
; Note: DPS exits opposite to the entry state unless an extra INC AUXR1 is
added

AUXR1EQU0A2h

4	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
3	GF3	**General Purpose Flag 3**
2	0	**Always Zero** This bit is stuck to logic 0 to allow INC AUXR1 instruction without affecting GF3 flag.
1	-	**Reserved for Data Pointer Extension**
0	DPS	**Data Pointer Select bit** Set to select second dual data pointer: DPTR1. Clear to select first dual data pointer: DPTR0.

Reset Value = XXXX 00X0b

Note: 1. ENBOOT is initialized with the invert BLJB at reset. See In-System Programming section.

EEPROM Data Memory

The 2K bytes on-chip EEPROM memory block is located at addresses 0000h to 07FFh of the XRAM/XRAM memory space and is selected by setting control bits in the EECON register. A read in the EEPROM memory is done with a MOVX instruction.

A physical write in the EEPROM memory is done in two steps: write data in the column latches and transfer of all data latches into an EEPROM memory row (programming).

The number of data written on the page may vary from 1 up to 128 Bytes (the page size). When programming, only the data written in the column latch is programmed and a ninth bit is used to obtain this feature. This provides the capability to program the whole memory by Bytes, by page or by a number of Bytes in a page. Indeed, each ninth bit is set when the writing the corresponding byte in a row and all these ninth bits are reset after the writing of the complete EEPROM row.

Write Data in the Column Latches

Data is written by byte to the column latches as for an external RAM memory. Out of the 11 address bits of the data pointer, the 4 MSBs are used for page selection (row) and 7 are used for byte selection. Between two EEPROM programming sessions, all the addresses in the column latches must stay on the same page, meaning that the 4 MSB must no be changed.

The following procedure is used to write to the column latches:

- Save and disable interrupt
- Set bit EEE of EECON register
- Load DPTR with the address to write
- Store A register with the data to be written
- Execute a MOVX @DPTR, A
- If needed loop the three last instructions until the end of a 128 Bytes page
- Restore interrupt

Note: The last page address used when loading the column latch is the one used to select the page programming address.

Programming

The EEPROM programming consists of the following actions:

- Write one or more Bytes of one page in the column latches. Normally, all Bytes must belong to the same page; if not, the last page address will be latched and the others discarded.
- Launch programming by writing the control sequence (50h followed by A0h) to the EECON register.
- EEBUSY flag in EECON is then set by hardware to indicate that programming is in progress and that the EEPROM segment is not available for reading.
- The end of programming is indicated by a hardware clear of the EEBUSY flag.

Note: The sequence 5xh and Axh must be executed without instructions between then otherwise the programming is aborted.

Read Data

The following procedure is used to read the data stored in the EEPROM memory:

- Save and disable interrupt
- Set bit EEE of EECON register
- Load DPTR with the address to read
- Execute a MOVX A, @DPTR
- Restore interrupt

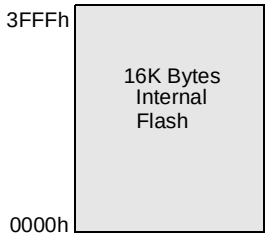
Program/Code Memory

The T89C51CC02 implement 16K Bytes of on-chip program/code memory.

The Flash memory increases EPROM and ROM functionality by in-circuit electrical erasure and programming. Thanks to the internal charge pump, the high voltage needed for programming or erasing Flash cells is generated on-chip using the standard V_{DD} voltage. Thus, the Flash memory can be programmed using only one voltage and allows In-System Programming (ISP). Hardware programming mode is also available using specific programming tool.

Figure 12. Program/Code Memory Organization



Flash Memory Architecture

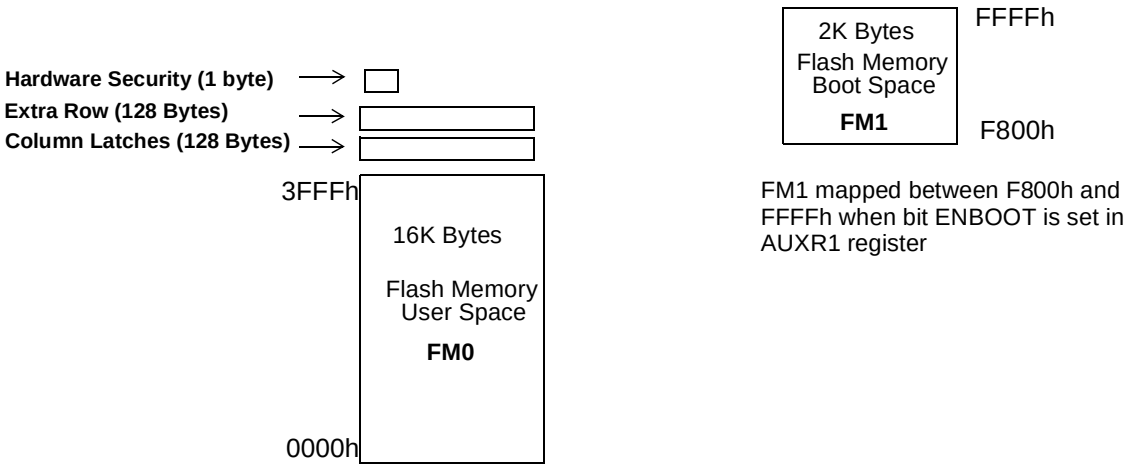
T89C51CC02 features two on-chip Flash memories:

- Flash memory FM0:
  containing 16K Bytes of program memory (user space) organized into 128 bytes pages,
- Flash memory FM1:
  2K Bytes for boot loader and Application Programming Interfaces (API).

The FM0 can be program by both parallel programming and Serial ISP whereas FM1 supports only parallel programming by programmers. The ISP mode is detailed in the 'In-System Programming' section.

All Read/Write access operations on Flash memory by user application are managed by a set of API described in the 'In-System Programming' section.

Figure 13. Flash Memory Architecture



FM0 Memory Architecture

The Flash memory is made up of 4 blocks (See Figure 13):

1. The memory array (user space) 16K Bytes
2. The Extra Row
3. The Hardware security bits
4. The column latch registers

User Space

This space is composed of a 16K Bytes Flash memory organized in 128 pages of 128 Bytes. It contains the user's application code.

Extra Row (XRow)

This row is a part of FM0 and has a size of 128 Bytes. The extra row may contain information for boot loader usage.

Hardware Security Byte

The Hardware security Byte space is a part of FM0 and has a size of 1 byte.
The 4 MSB can be read/written by software, the 4 LSB can only be read by software and written by hardware in parallel mode.

Column Latches

The column latches, also part of FM0, have a size of full page (128 Bytes).
The column latches are the entrance buffers of the three previous memory locations (user array, XROW and Hardware security byte).

Cross Flash Memory Access Description

The FM0 memory can be programmed as describe on Table 21. Programming FM0 from FM0 is impossible.

The FM1 memory can be program only by parallel programming.

Table 21 show all software Flash access allowed.

Table 21. Cross Flash Memory Access

Code executing from		Action	FM0 (user Flash)	FM1 (boot Flash)
	FM0 (user Flash)	Read	ok	-
		Load column latch	ok	-
		Write	-	-
	FM1 (boot Flash)	Read	ok	ok
		Load column latch	ok	-
		Write	ok	-

Overview of FM0 Operations

The CPU interfaces the Flash memory through the FCON register and AUXR1 register.

These registers are used to:

- Map the memory spaces in the adressable space
- Launch the programming of the memory spaces
- Get the status of the Flash memory (busy/not busy)

Mapping of the Memory Space

By default, the user space is accessed by MOVC instruction for read only. The column latches space is made accessible by setting the FPS bit in FCON register. Writing is possible from 0000h to 3FFFh, address bits 6 to 0 are used to select an address within a page while bits 14 to 7 are used to select the programming address of the page.
Setting FPS bit takes precedence on the EEE bit in EECON register.

The other memory spaces (user, extra row, hardware security) are made accessible in the code segment by programming bits FMOD0 and FMOD1 in FCON register in accordance with Table 22. A MOVC instruction is then used for reading these spaces.

Table 22. FM0 blocks Select bits

FMOD1	FMOD0	FM0 Adressable Space
0	0	User (0000h-3FFFh)
0	1	Extra Row(FF80h-FFFFh)
1	0	Hardware Security Byte (0000h)
1	1	Reserved

Launching Programming

FPL3:0 bits in FCON register are used to secure the launch of programming. A specific sequence must be written in these bits to unlock the write protection and to launch the programming. This sequence is 5xh followed by Axh. Table 23 summarizes the memory spaces to program according to FMOD1:0 bits.

Table 23. Programming Spaces

	Write to FCON				
	FPL3:0	FPS	FMOD1	FMOD0	Operation
User	5	x	0	0	No action
	A	x	0	0	Write the column latches in user space
Extra Row	5	x	0	1	No action
	A	x	0	1	Write the column latches in extra row space
Hardware Security Byte	5	x	1	0	No action
	A	x	1	0	Write the fuse bits space
Reserved	5	x	1	1	No action
	A	x	1	1	No action

Note: The sequence 5xh and Axh must be executing without instructions between them otherwise the programming is aborted.
Interrupts that may occur during programming time must be disabled to avoid any spurious exit of the programming mode.

Status of the Flash Memory

The bit FBUSY in FCON register is used to indicate the status of programming.

FBUSY is set when programming is in progress.

Selecting FM1

The bit ENBOOT in AUXR1 register is used to map FM1 from F800h to FFFFh.

Loading the Column Latches

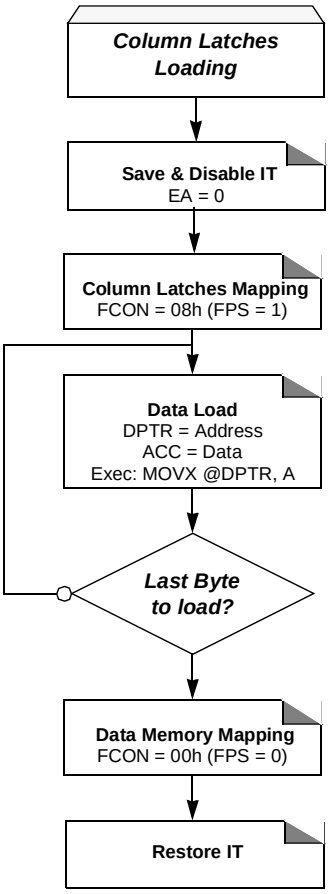
Any number of data from 1 byte to 128 Bytes can be loaded in the column latches. This provides the capability to program the whole memory by byte, by page or by any number of Bytes in a page.

When programming is launched, an automatic erase of the locations loaded in the column latches is first performed, then programming is effectively done. Thus no page or block erase is needed and only the loaded data are programmed in the corresponding page.

The following procedure is used to load the column latches and is summarized in Figure 14:

- Save then disable interrupt and map the column latch space by setting FPS bit.
- Load the DPTR with the address to load.
- Load Accumulator register with the data to load.
- Execute the MOVX @DPTR, A instruction.
- If needed loop the three last instructions until the page is completely loaded.
- unmap the column latch and Restore Interrupt

Figure 14. Column Latches Loading Procedure(1)



Note: 1. The last page address used when loading the column latch is the one used to select the page programming address.

Programming the Flash Spaces

User

The following procedure is used to program the User space and is summarized in Figure 15:

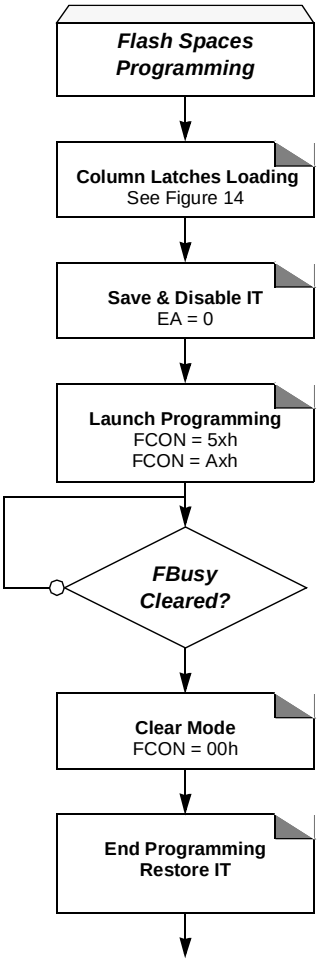
- Load up to one page of data in the column latches from address 0000h to 3FFFh.
- Save then disable the interrupts.
- Launch the programming by writing the data sequence 50h followed by A0h in FCON register.This step must be executed from FM1.
  The end of the programming indicated by the FBUSY flag cleared.
- Restore the interrupts.

Extra Row

The following procedure is used to program the Extra Row space and is summarized in Figure 15:

- Load data in the column latches from address FF80h to FFFFh.
- Save then disable the interrupts.
- Launch the programming by writing the data sequence 52h followed by A2h in FCON register. This step of the procedure must be executed from FM1.
  The end of the programming indicated by the FBUSY flag cleared.
- Restore the interrupts.

Figure 15. Flash and Extra row Programming Procedure

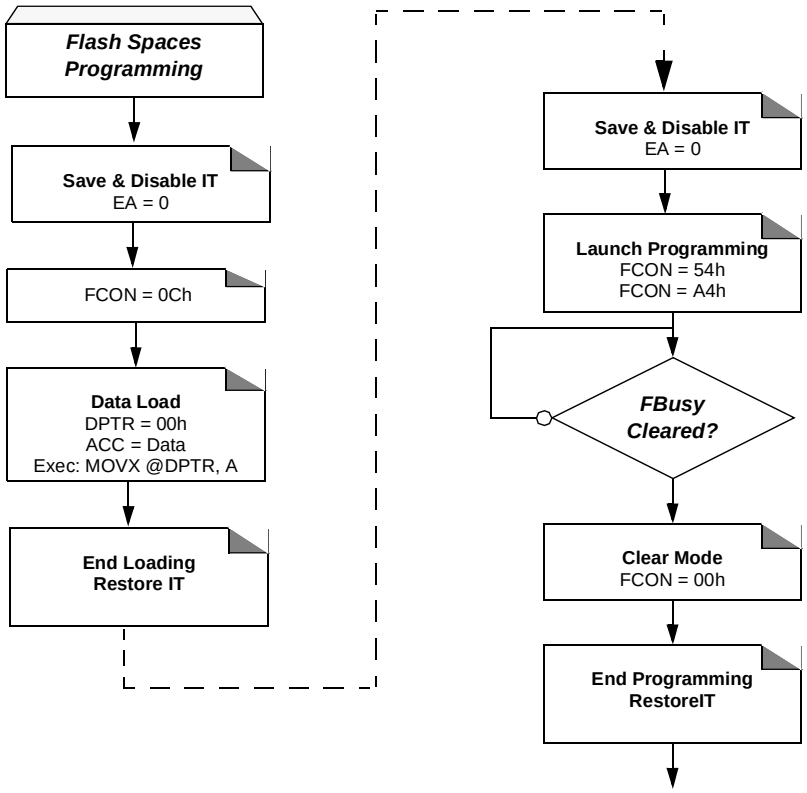


Hardware Security Byte

The following procedure is used to program the Hardware Security Byte space and is summarized in Figure 16:

- Set FPS and map Hardware byte (FCON = 0x0C)
- Save then disable the interrupts.
- Load DPTR at address 0000h.
- Load Accumulator register with the data to load.
- Execute the MOVX @DPTR, A instruction.
- Launch the programming by writing the data sequence 54h followed by A4h in FCON register. This step of the procedure must be executed from FM1.
  The end of the programming indicated by the FBusy flag cleared.
- Restore the interrupts

Figure 16. Hardware Programming Procedure



Reading the Flash Spaces

User

The following procedure is used to read the User space:

- Read one byte in Accumulator by executing MOVC A,@A+DPTR with A+DPTR is the address of the code byte to read.

Note: FCON must be cleared (00h) when not used.

Extra Row

The following procedure is used to read the Extra Row space and is summarized in Figure 17:

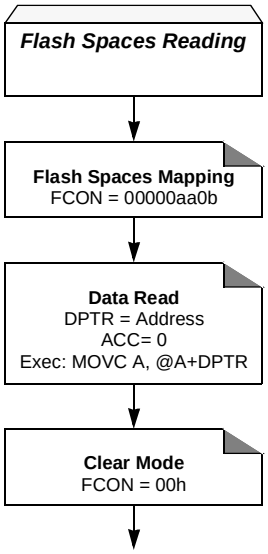
- Map the Extra Row space by writing 02h in FCON register.
- Read one byte in Accumulator by executing MOVC A,@A+DPTR with A= 0 & DPTR= FF80h to FFFFh.
- Clear FCON to unmap the Extra Row.

Hardware Security Byte

The following procedure is used to read the Hardware Security Byte and is summarized in Figure 17:

- Map the Hardware Security space by writing 04h in FCON register.
- Read the byte in Accumulator by executing MOVC A,@A+DPTR with A= 0 & DPTR= 0000h.
- Clear FCON to unmap the Hardware Security Byte.

Figure 17. Reading Procedure



Note: aa = 10 for the Hardware Security Byte.

Flash Protection from Parallel Programming

The three lock bits in Hardware Security Byte (See 'In-System Programming' section) are programmed according to Table 24 provide different level of protection for the on-chip code and data located in FM0 and FM1.

The only way to write this bits are the parallel mode. They are set by default to level 3.

Table 24. Program Lock bit

Program Lock bits				
Security Level	LB0	LB1	LB2	**Protection Description**
1	U	U	U	No program lock features enabled.
2	P	U	U	Parallel programming of the Flash is disabled.
3	U	P	U	Same as 2, also verify through parallel programming interface is disabled. This is the factory defaul programming.
4	U	U	P	Same as 3

Note: 1. Program Lock bits
U: unprogrammed
P: programmed

WARNING: Security level 2, 3 and 4 should only be programmed after Flash and Core verification.

Preventing Flash Corruption

See Section "Power Management".

Table 25. FCON Register

3	FPS	**Flash Map Program Space** Set to map the column latch space in the data memory space. Clear to re-map the data memory space.
2 - 1	FMOD1:0	**Flash Mode** See Table 22 or Table 23.
0	FBUSY	**Flash Busy** Set by hardware when programming is in progress. Clear by hardware when programming is done. Can not be changed by software.

Reset Value = 0000 0000b

Operation Cross Memory Access

Space addressable in read and write are:

- RAM
- ERAM (Expanded RAM access by movx)
- EEPROM DATA
- FM0 (user flash)
- Hardware byte
- XROW
- Boot Flash
- Flash Column latch

The table below provides the different kind of memory which can be accessed from different code location.

Table 26. Cross Memory Access

	Action	RAM	ERAM	Boot FLASH	FM0	E² Data	Hardware Byte	XROW
boot FLASH	Read			OK	OK	OK	OK	-
	Write			-	OK(1)	OK(1)	OK(1)	OK(1)
FM0	Read			OK	OK	OK	-OK	-
	Write			-	OK (idle)	OK(1)	-	-OK

Note: 1. RWW: Read While Write

Sharing Instructions

Table 27. Instructions shared

					F800h to FFFFh	OK			
				0	X	NA			
			1	1	X		OK		
				0	X	NA			
	0	1	X	1	0000h to 007h See (2)			OK	
				0		NA			
	1	0	X	1	X				OK
				0		NA			
	1	1	X	1	000h to 3FFFh		OK		
				0		NA			

1. For DPTR higher than 007Fh only lowest 7 bits are decoded, thus the behavior is the same as for addresses from 0000h to 007Fh
2. For DPTR higher than 007Fh only lowest 7 bits are decoded, thus the behavior is the same as for addresses from 0000h to 007Fh

In-System Programming (ISP)

With the implementation of the User Space (FM0) and the Boot Space (FM1) in Flash technology the T89C51CC02 allows the system engineer the development of applications with a very high level of flexibility. This flexibility is based on the possibility to alter the customer program at any stages of a product's life:

- Before mounting the chip on the PCB, FM0 flash can be programmed with the application code. FM1 is always preprogrammed by Atmel with a bootloader (chip can be ordered with CAN bootloader or UART bootloader).(1)
- Once the chip is mounted on the PCB, it can be programmed by serial mode via the CAN bus or UART.

Note: 1. The user can also program his own bootloader in FM1.

This ISP allows code modification over the total lifetime of the product.

Besides the default Bootloaders Atmel provide customers all the needed Application-Programming-Interfaces (API) which are needed for the ISP. The API are located in the Boot memory.

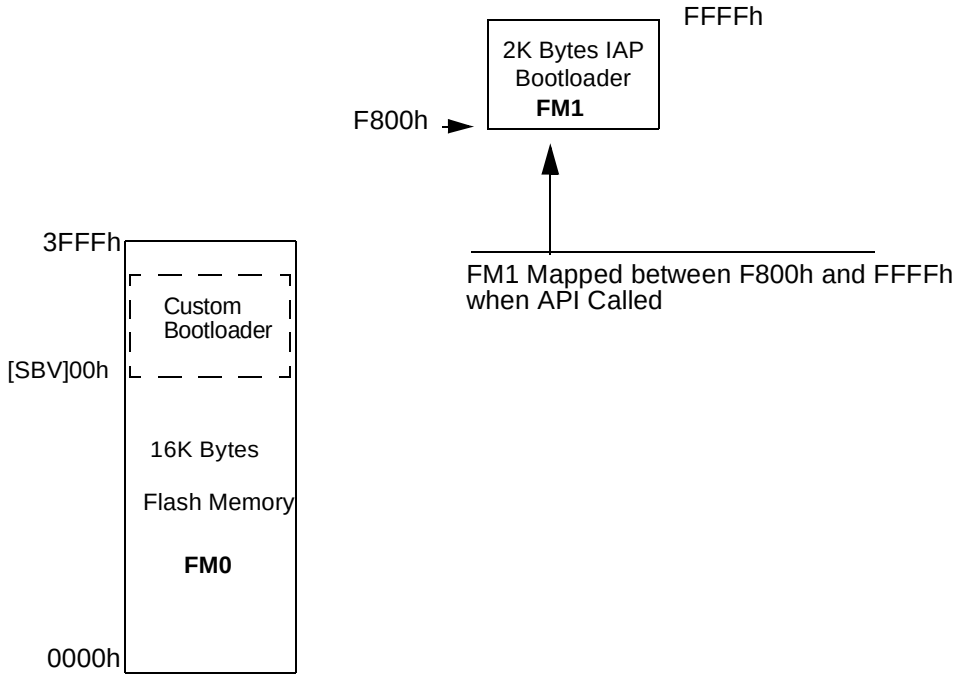
This allow the customer to have a full use of the 16-Kbyte user memory.

Flash Programming and Erasure

There are three methods for programming the Flash memory:

- The Atmel bootloader located in FM1 is activated by the application. Low level API routines (located in FM1)will be used to program FM0. The interface used for serial downloading to FM0 is the UART or the CAN. API can be called also by user's bootloader located in FM0 at [SBV]00h.
- A further method exist in activating the Atmel boot loader by hardware activation. See the Section "Hardware Security Byte".
- The FM0 can be programmed also by the parallel mode using a programmer.

Figure 18. Flash Memory Mapping



Boot Process

Software Boot Process Example

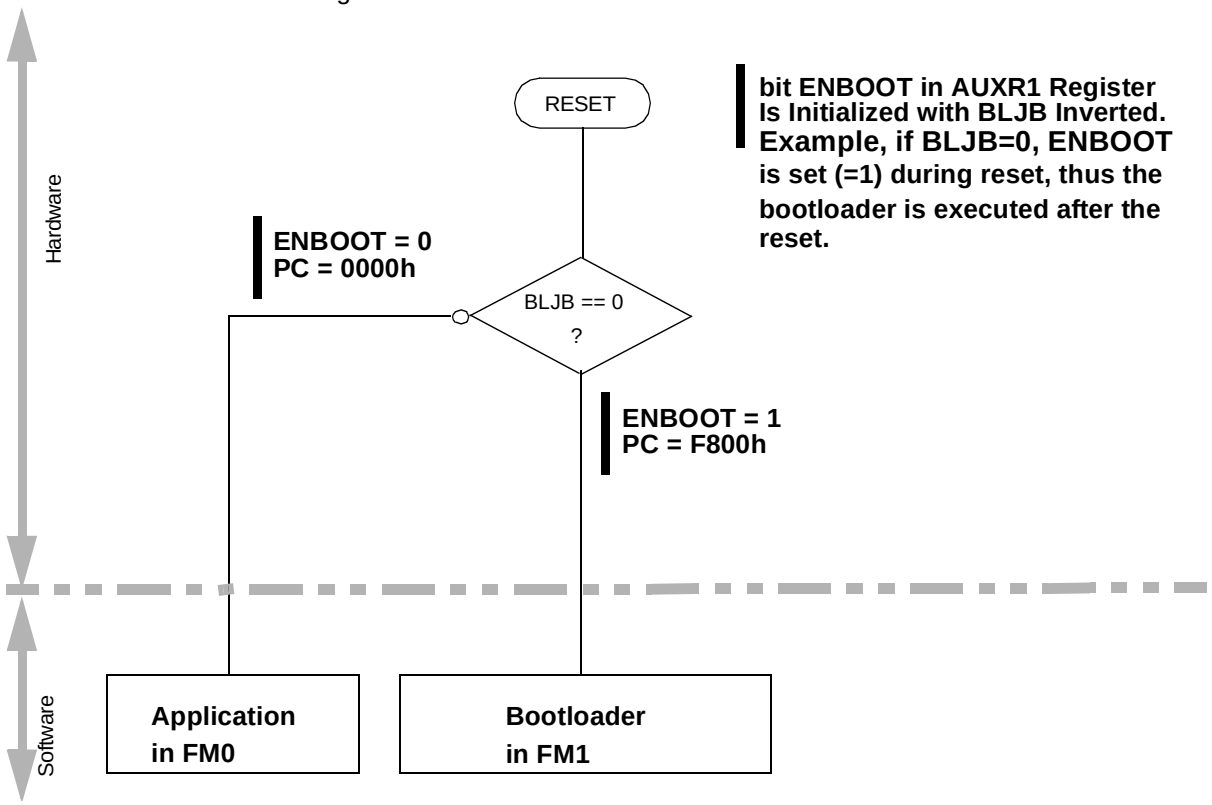
Many algorithms can be used for the software boot process. Below are descriptions of the different flags and Bytes.

Boot Loader Jump bit (BLJB):
- This bit indicates if on RESET the user wants to jump to this application at address @0000h on FM0 or execute the boot loader at address @F800h on FM1.
- BLJB = 0 (i.e. bootloader FM1 executed after a reset) is the default Atmel factory programming.
-To read or modify this bit, the APIs are used.

Boot Vector Address (SBV):
- This byte contains the MSB of the user boot loader address in FM0.
- The default value of SBV is FCh (no user boot loader in FM0).
- To read or modify this byte, the APIs are used.

Extra Byte (EB) & Boot Status Byte (BSB):
- These Bytes are reserved for customer use.
- To read or modify these Bytes, the APIs are used.

Figure 19. Hardware Boot Process Algorithm



Application-Programming-Interface

Several Application Program Interface (API) calls are available for use by an application program to permit selective erasing and programming of Flash pages. All calls are made by functions.

All these APIs are described in detail in the following documents on the Atmel web site.

- Datasheet Bootloader CAN T89C51CC02.
- Datasheet Bootloader UART T89C51CC02.

XROW Bytes

The EXTRA ROW (XROW) includes 128 bytes. Some of these bytes are used for specific purpose in conjonction with the bootloader.

Table 31. XROW Mapping

Description	Default Value	Address
Copy of the Manufacturer Code	58h	30h
Copy of the Device ID#1: Family code	D7h	31h
Copy of the Device ID#2: Memories size and type	BBh	60h
Copy of the Device ID#3: Name and Revision	FFh	61h

Hardware Conditions

It is possible to force the controller to execute the bootloader after a Reset with hardware conditions.

During the first programming, the user can define a configuration on Port1 that will be recognized by the chip as the hardware conditions during a Reset. If this condition is met, the chip will start executing the bootloader at the end of the Reset.

See a detailed description in the applicable Document.

- Datasheet Bootloader CAN T89C51CC02.
- Datasheet Bootloader UART T89C51CC02.

Hardware Security Byte

Table 32. Hardware Security byte

7	6	5	4	3	2	1	0
X2B	**BLJB**	**-**	**-**	**-**	**LB2**	**LB1**	**LB0**

Bit Number	Bit Mnemonic	Description
7	X2B	**X2 bit** Set this bit to start in standard mode Clear this bit to start in X2 Mode.
6	BLJB	**Boot Loader Jump bit** - 1: To start the user's application on next RESET (@0000h) located in FM0, - 0: To start the boot loader(@F800h) located in FM1.
5 - 3	-	**Reserved** The value read from these bits are indeterminate.
2 - 0	LB2:0	**Lock bits** (see Table 22)

After erasing the chip in parallel mode, the default value is : FFh

The erasing in ISP mode (from bootloader) does not modify this byte.

Notes: 1. Only the 4 MSB bits can be accessed by software.
2. The 4 LSB bits can only be accessed by parallel mode.

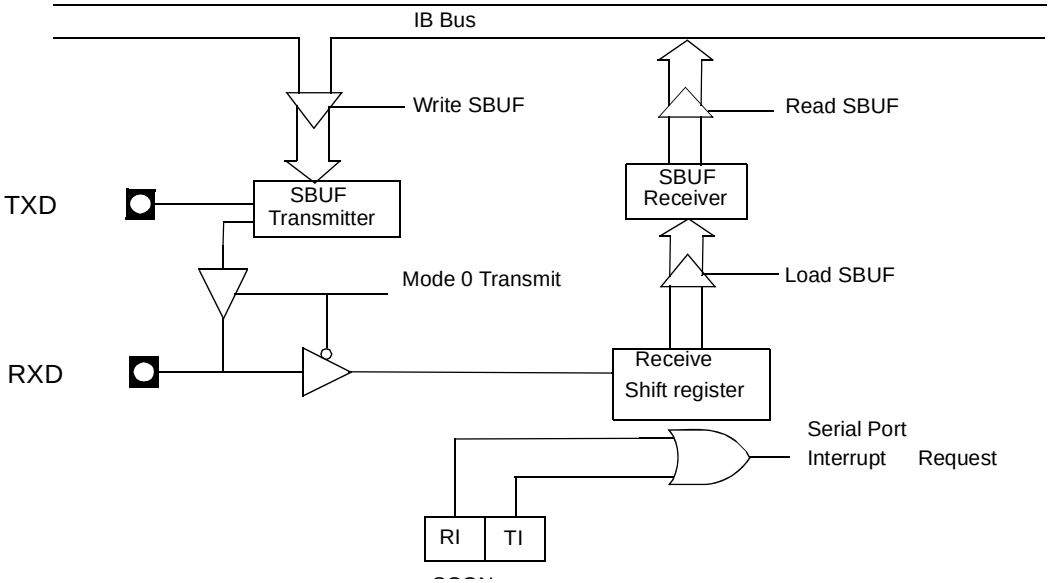
Serial I/O Port

The T89C51CC02 I/O serial port is compatible with the I/O serial port in the 80C52. It provides both synchronous and asynchronous communication modes. It operates as a Universal Asynchronous Receiver and Transmitter (UART) in three full-duplex modes (Modes 1, 2 and 3). Asynchronous transmission and reception can occur simultaneously and at different baud rates

Serial I/O port includes the following enhancements:

- Framing error detection
- Automatic address recognition

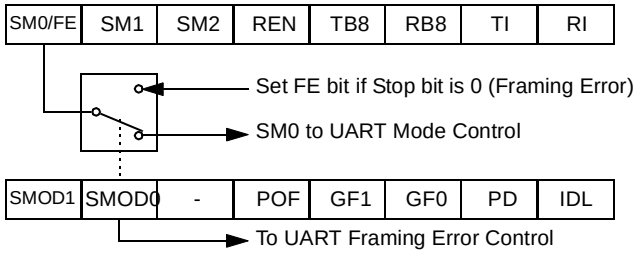
Figure 20. Serial I/O Port Block Diagram



Framing Error Detection

Framing bit error detection is provided for the three asynchronous modes. To enable the framing bit error detection feature, set SMOD0 bit in PCON register.

Figure 21. Framing Error Block Diagram



When this feature is enabled, the receiver checks each incoming data frame for a valid stop bit. An invalid stop bit may result from noise on the serial lines or from simultaneous transmission by two CPUs. If a valid stop bit is not found, the Framing Error bit (FE) in SCON register bit is set.

The software may examine the FE bit after each reception to check for data errors. Once set, only software or a reset clears the FE bit. Subsequently received frames with valid stop bits cannot clear the FE bit. When the FE feature is enabled, RI rises on the stop bit instead of the last data bit (See Figure 22 and Figure 23).

Figure 22. UART Timing in Mode 1

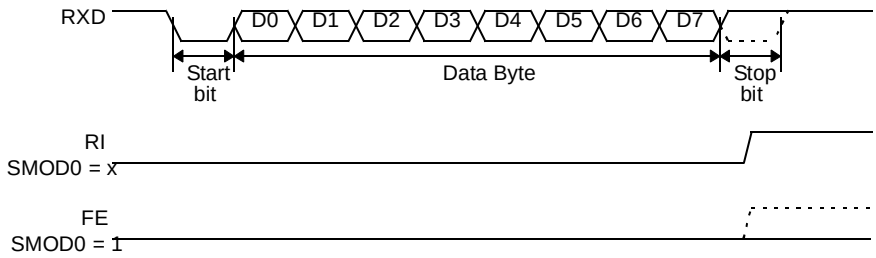


Figure 23. UART Timing in Modes 2 and 3

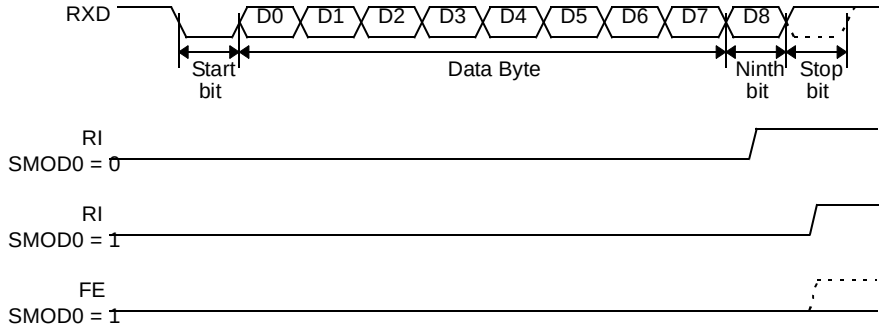

Automatic Address Recognition

The automatic address recognition feature is enabled when the multiprocessor communication feature is enabled (SM2 bit in SCON register is set).

Implemented in the hardware, automatic address recognition enhances the multiprocessor communication feature by allowing the serial port to examine the address of each incoming command frame. Only when the serial port recognizes its own address will the receiver set the RI bit in the SCON register to generate an interrupt. This ensures that the CPU is not interrupted by command frames addressed to other devices.
If necessary, the user can enable the automatic address recognition feature in mode 1. In this configuration, the stop bit takes the place of the ninth data bit. bit RI is set only when the received command frame address matches the device's address and is terminated by a valid stop bit.

To support automatic address recognition, a device is identified by a given address and a broadcast address.

Note: The multiprocessor communication and automatic address recognition features cannot be enabled in mode 0 (i.e. setting SM2 bit in SCON register in mode 0 has no effect).

Given Address

Each device has an individual address that is specified in the SADDR register; the SADEN register is a mask byte that contains don't-care bits (defined by zeros) to form the device's given address. The don't-care bits provide the flexibility to address one or more slaves at a time. The following example illustrates how a given address is formed. To address a device by its individual address, the SADEN mask byte must be `1111 1111b`.
For example:

```
SADDR0101 0110b
SADEN1111 1100b
Given0101 01XXb
```

Here is an example of how to use given addresses to address different slaves:

```
Slave A:SADDR1111 0001b
    SADEN1111 1010b
    Given1111 0X0Xb

Slave B:SADDR1111 0011b
    SADEN1111 1001b
    Given1111 0XX1b

Slave C:SADDR1111 0011b
    SADEN1111 1101b
    Given1111 00X1b
```

The SADEN byte is selected so that each slave may be addressed separately.
For slave A, bit 0 (the LSB) is a don't-care bit; for slaves B and C, bit 0 is a 1. To communicate with slave A only, the master must send an address where bit 0 is clear (e.g. `1111 0000b`).
For slave A, bit 1 is a 0; for slaves B and C, bit 1 is a don't care bit. To communicate with slaves A and B, but not slave C, the master must send an address with bits 0 and 1 both set (e.g. `1111 0011b`).
To communicate with slaves A, B and C, the master must send an address with bit 0 set, bit 1 clear, and bit 2 clear (e.g. `1111 0001b`).

Broadcast Address

A broadcast address is formed from the logical OR of the SADDR and SADEN registers with zeros defined as don't-care bits, e.g.:

```
SADDR 0101 0110b
SADEN 1111 1100b
SADDR OR SADEN1111 111Xb
```

The use of don't-care bits provides flexibility in defining the broadcast address, however in most applications, a broadcast address is FFh. The following is an example of using broadcast addresses:

```
Slave A:SADDR1111 0001b
    SADEN1111 1010b
    Given1111 1X11b,

Slave B:SADDR1111 0011b
    SADEN1111 1001b
    Given1111 1X11B,

Slave C:SADDR=1111 0010b
    SADEN1111 1101b
    Given1111 1111b
```

For slaves A and B, bit 2 is a don't care bit; for slave C, bit 2 is set. To communicate with all of the slaves, the master must send an address FFh. To communicate with slaves A and B, but not slave C, the master can send and address FBh.

Registers

Table 33. SCON Register

Not bit addressable

Timers/Counters

The T89C51CC02 implements two general-purpose, 16-bit Timers/Counters. Such are identified as Timer 0 and Timer 1, and can be independently configured to operate in a variety of modes as a Timer or an event Counter. When operating as a Timer, the Timer/Counter runs for a programmed length of time, then issues an interrupt request. When operating as a Counter, the Timer/Counter counts negative transitions on an external pin. After a preset number of counts, the Counter issues an interrupt request.
The various operating modes of each Timer/Counter are described in the following sections.

Timer/Counter Operations

A basic operation is Timer registers THx and TLx (x = 0, 1) connected in cascade to form a 16-bit Timer. Setting the run control bit (TRx) in TCON register (See Figure 38) turns the Timer on by allowing the selected input to increment TLx. When TLx overflows it increments THx; when THx overflows it sets the Timer overflow flag (TFx) in TCON register. Setting the TRx does not clear the THx and TLx Timer registers. Timer registers can be accessed to obtain the current count or to enter preset values. They can be read at any time but TRx bit must be cleared to preset their values, otherwise the behavior of the Timer/Counter is unpredictable.

The C/Tx# control bit selects Timer operation or Counter operation by selecting the divided-down peripheral clock or external pin Tx as the source for the counted signal. TRx bit must be cleared when changing the mode of operation, otherwise the behavior of the Timer/Counter is unpredictable.
For Timer operation (C/Tx# = 0), the Timer register counts the divided-down peripheral clock. The Timer register is incremented once every peripheral cycle (6 peripheral clock periods). The Timer clock rate is $f_{PER}/6$, i.e. $f_{OSC}/12$ in standard mode or $f_{OSC}/6$ in X2 Mode.

For Counter operation (C/Tx# = 1), the Timer register counts the negative transitions on the Tx external input pin. The external input is sampled every peripheral cycles. When the sample is high in one cycle and low in the next one, the Counter is incremented. Since it takes 2 cycles (12 peripheral clock periods) to recognize a negative transition, the maximum count rate is $f_{PER}/12$, i.e. $f_{OSC}/24$ in standard mode or $f_{OSC}/12$ in X2 Mode. There are no restrictions on the duty cycle of the external input signal, but to ensure that a given level is sampled at least once before it changes, it should be held for at least one full peripheral cycle.

Timer 0

Timer 0 functions as either a Timer or event Counter in four modes of operation. Figure 24 through Figure 27 show the logical configuration of each mode.

Timer 0 is controlled by the four lower bits of TMOD register (See Figure 39) and bits 0, 1, 4 and 5 of TCON register (See Figure 38). TMOD register selects the method of Timer gating (GATE0), Timer or Counter operation (T/C0#) and mode of operation (M10 and M00). TCON register provides Timer 0 control functions: overflow flag (TF0), run control bit (TR0), interrupt flag (IE0) and interrupt type control bit (IT0).
For normal Timer operation (GATE0 = 0), setting TR0 allows TL0 to be incremented by the selected input. Setting GATE0 and TR0 allows external pin INT0# to control Timer operation.

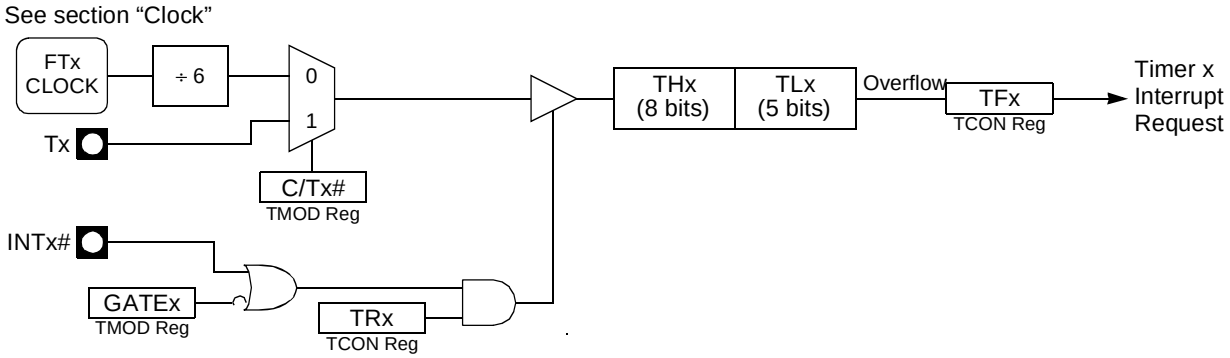
Timer 0 overflow (count rolls over from all 1s to all 0s) sets TF0 flag generating an interrupt request.

It is important to stop Timer/Counter before changing mode.

Mode 0 (13-bit Timer)

Mode 0 configures Timer 0 as an 13-bit Timer which is set up as an 8-bit Timer (TH0 register) with a modulo 32 prescaler implemented with the lower five bits of TL0 register (See Figure 24). The upper three bits of TL0 register are indeterminate and should be ignored. Prescaler overflow increments TH0 register.

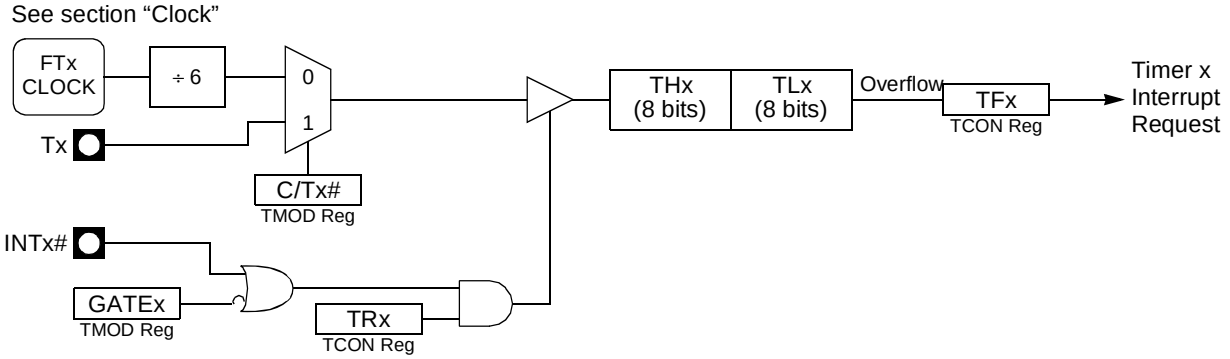
Figure 24. Timer/Counter x (x= 0 or 1) in Mode 0



Mode 1 (16-bit Timer)

Mode 1 configures Timer 0 as a 16-bit Timer with TH0 and TL0 registers connected in cascade (See Figure 25). The selected input increments TL0 register.

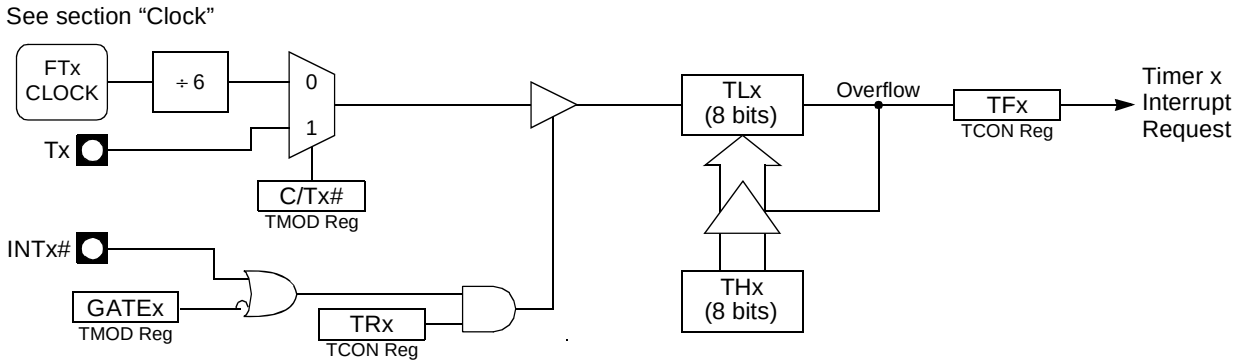
Figure 25. Timer/Counter x (x= 0 or 1) in Mode 1



Mode 2 (8-bit Timer with Auto-Reload)

Mode 2 configures Timer 0 as an 8-bit Timer (TL0 register) that automatically reloads from TH0 register (See Figure 26). TL0 overflow sets TF0 flag in TCON register and reloads TL0 with the contents of TH0, which is preset by software. When the interrupt request is serviced, hardware clears TF0. The reload leaves TH0 unchanged. The next reload value may be changed at any time by writing it to TH0 register.

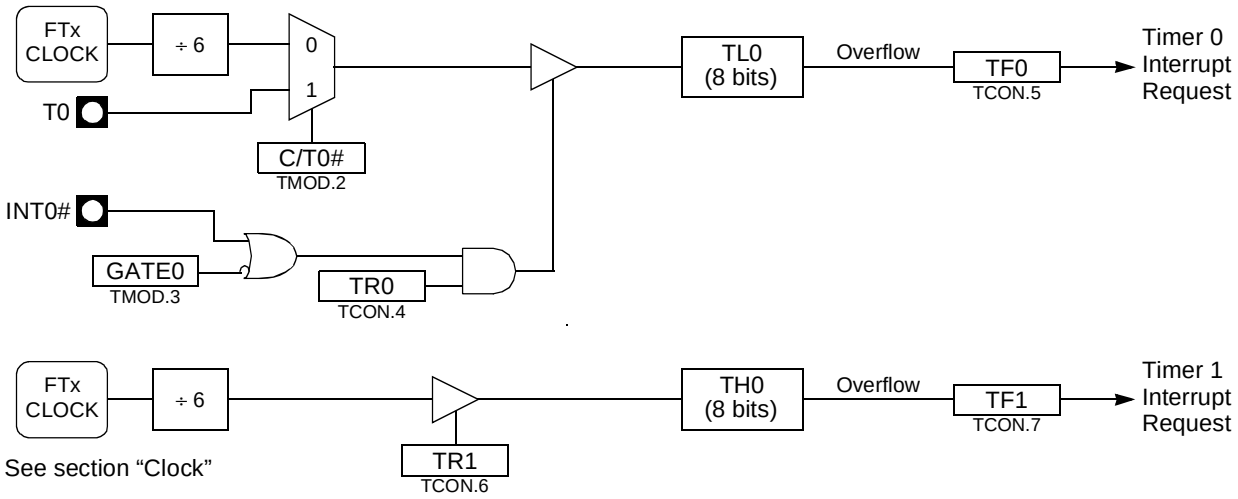
Figure 26. Timer/Counter x (x= 0 or 1) in Mode 2



Mode 3 (Two 8-bit Timers)

Mode 3 configures Timer 0 such that registers TL0 and TH0 operate as separate 8-bit Timers (See Figure 27). This mode is provided for applications requiring an additional 8-bit Timer or Counter. TL0 uses the Timer 0 control bits C/T0# and GATE0 in TMOD register, and TR0 and TF0 in TCON register in the normal manner. TH0 is locked into a Timer function (counting F_{PER} /6) and takes over use of the Timer 1 interrupt (TF1) and run control (TR1) bits. Thus, operation of Timer 1 is restricted when Timer 0 is in mode 3.

Figure 27. Timer/Counter 0 in Mode 3: Two 8-bit Counters



Timer 1

Timer 1 is identical to Timer 0 excepted for Mode 3 which is a hold-count mode. Following comments help to understand the differences:

- Timer 1 functions as either a Timer or event Counter in three modes of operation. Figure 24 to Figure 26 show the logical configuration for modes 0, 1, and 2. Timer 1’s mode 3 is a hold-count mode.
- Timer 1 is controlled by the four high-order bits of TMOD register (See Figure 39) and bits 2, 3, 6 and 7 of TCON register (See Figure 38). TMOD register selects the method of Timer gating (GATE1), Timer or Counter operation (C/T1#) and mode of operation (M11 and M01). TCON register provides Timer 1 control functions: overflow flag (TF1), run control bit (TR1), interrupt flag (IE1) and interrupt type control bit (IT1).
- Timer 1 can serve as the Baud Rate Generator for the Serial Port. Mode 2 is best suited for this purpose.

- For normal Timer operation (GATE1= 0), setting TR1 allows TL1 to be incremented by the selected input. Setting GATE1 and TR1 allows external pin INT1# to control Timer operation.
- Timer 1 overflow (count rolls over from all 1s to all 0s) sets the TF1 flag generating an interrupt request.
- When Timer 0 is in mode 3, it uses Timer 1's overflow flag (TF1) and run control bit (TR1). For this situation, use Timer 1 only for applications that do not require an interrupt (such as a Baud Rate Generator for the Serial Port) and switch Timer 1 in and out of mode 3 to turn it off and on.
- It is important to stop Timer/Counter before changing mode.

Mode 0 (13-bit Timer)

Mode 0 configures Timer 1 as a 13-bit Timer, which is set up as an 8-bit Timer (TH1 register) with a modulo-32 prescaler implemented with the lower 5 bits of the TL1 register (See Figure 24). The upper 3 bits of TL1 register are ignored. Prescaler overflow increments TH1 register.

Mode 1 (16-bit Timer)

Mode 1 configures Timer 1 as a 16-bit Timer with TH1 and TL1 registers connected in cascade (See Figure 25). The selected input increments TL1 register.

Mode 2 (8-bit Timer with Auto-Reload)

Mode 2 configures Timer 1 as an 8-bit Timer (TL1 register) with automatic reload from TH1 register on overflow (See Figure 26). TL1 overflow sets TF1 flag in TCON register and reloads TL1 with the contents of TH1, which is preset by software. The reload leaves TH1 unchanged.

Mode 3 (Halt)

Placing Timer 1 in mode 3 causes it to halt and hold its count. This can be used to halt Timer 1 when TR1 run control bit is not available i.e. when Timer 0 is in mode 3.

Interrupt

Each Timer handles one interrupt source that is the timer overflow flag TF0 or TF1. This flag is set every time an overflow occurs. Flags are cleared when vectoring to the Timer interrupt routine. Interrupts are enabled by setting ETx bit in IEN0 register. This assumes interrupts are globally enabled by setting EA bit in IEN0 register.

Timer 2

The T89C51CC02 Timer 2 is compatible with Timer 2 in the 80C52.

It is a 16-bit timer/counter: the count is maintained by two eightbit timer registers, TH2 and TL2 that are cascade-connected. It is controlled by T2CON register (See Table 45) and T2MOD register (See Table 46). Timer 2 operation is similar to Timer 0 and Timer 1. C/$\overline{T2}$ selects $F_{T2\ clock}/6$ (timer operation) or external pin T2 (counter operation) as timer clock. Setting TR2 allows TL2 to be incremented by the selected input.

Timer 2 includes the following enhancements:

- Auto-reload mode (up or down counter)
- Programmable clock-output

Auto-Reload Mode

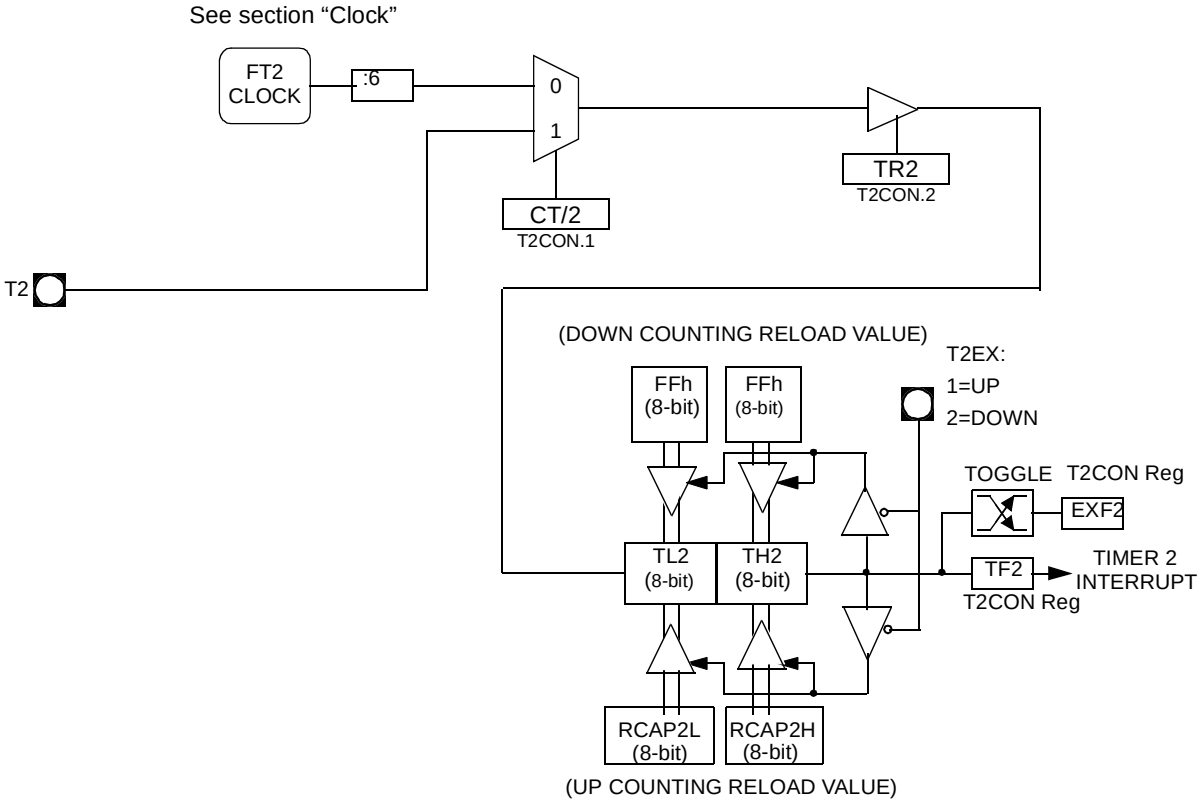
The auto-reload mode configures Timer 2 as a 16-bit timer or event counter with automatic reload. This feature is controlled by the DCEN bit in T2MOD register (See Table 45). Setting the DCEN bit enables Timer 2 to count up or down as shown in Figure 29. In this mode the T2EX pin controls the counting direction.

When T2EX is high, Timer 2 counts up. Timer overflow occurs at FFFFh which sets the TF2 flag and generates an interrupt request. The overflow also causes the 16-bit value in RCAP2H and RCAP2L registers to be loaded into the timer registers TH2 and TL2.

When T2EX is low, Timer 2 counts down. Timer underflow occurs when the count in the timer registers TH2 and TL2 equals the value stored in RCAP2H and RCAP2L registers. The underflow sets TF2 flag and reloads FFFFh into the timer registers.

The EXF2 bit toggles when Timer 2 overflow or underflow, depending on the direction of the count. EXF2 does not generate an interrupt. This bit can be used to provide 17-bit resolution.

Figure 29. Auto-Reload Mode Up/Down Counter



Programmable Clock-Output

In clock-out mode, Timer 2 operates as a 50%-duty-cycle, programmable clock generator (Figure 30). The input clock increments TL2 at frequency $f_{OSC}/2$. The timer repeatedly counts to overflow from a loaded value. At overflow, the contents of RCAP2H and RCAP2L registers are loaded into TH2 and TL2. In this mode, Timer 2 overflows do not generate interrupts. The formula gives the clock-out frequency depending on the system oscillator frequency and the value in the RCAP2H and RCAP2L registers:

$$Clock-OutFrequency = \frac{FT2clock}{4 \times (65536 - RCAP2H/RCAP2L)}$$

For a 16 MHz system clock in x1 mode, Timer 2 has a programmable frequency range of 61 Hz ($f_{OSC}/2^{16}$) to 4 MHz ($f_{OSC}/4$). The generated clock signal is brought out to T2 pin (P1.0).

Timer 2 is programmed for the clock-out mode as follows:

- Set T2OE bit in T2MOD register.
- Clear C/$\overline{T2}$ bit in T2CON register.
- Determine the 16-bit reload value from the formula and enter it in RCAP2H/RCAP2L registers.
- Enter a 16-bit initial value in timer registers TH2/TL2. It can be the same as the reload value or different depending on the application.
- To start the timer, set TR2 run control bit in T2CON register.

It is possible to use Timer 2 as a baud rate generator and a clock generator simultaneously. For this configuration, the baud rates and clock frequencies are not independent since both functions use the values in the RCAP2H and RCAP2L registers.

Watchdog Timer

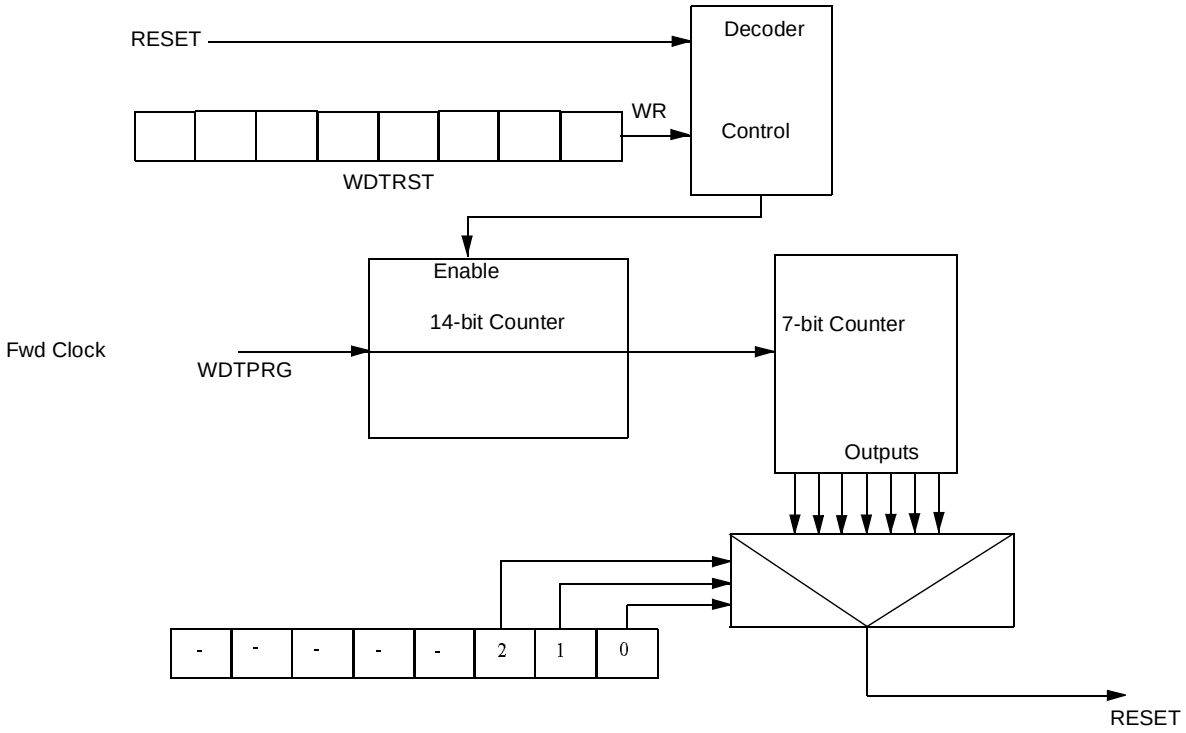
T89C51CC02 contains a powerful programmable hardware Watchdog Timer (WDT) that automatically resets the chip if it software fails to reset the WDT before the selected time interval has elapsed. It permits large Timeout ranging from 16ms to 2s @f_{OSC} = 12 MHz in X1 mode.

This WDT consists of a 14-bit counter plus a 7-bit programmable counter, a Watchdog Timer reset register (WDTRST) and a Watchdog Timer programming (WDTPRG) register. When exiting reset, the WDT is -by default- disable.

To enable the WDT, the user has to write the sequence 1EH and E1H into WDTRST register with no instruction between the two writes. When the Watchdog Timer is enabled, it will increment every machine cycle while the oscillator is running and there is no way to disable the WDT except through reset (either hardware reset or WDT overflow reset). When WDT overflows, it will generate an output RESET pulse at the RST pin. The RESET pulse duration is 96xT_{OSC}, where T_{OSC}=1/f_{OSC}. To make the best use of the WDT, it should be serviced in those sections of code that will periodically be executed within the time required to prevent a WDT reset

Note: When the watchdog is enable it is impossible to change its period.

Figure 31. Watchdog Timer



Watchdog Programming

The three lower bits (S0, S1, S2) located into WDTPRG register permit to program the WDT duration.

Table 50. Machine Cycle Count

S2	S1	S0	Machine Cycle Count
0	0	0	$2^{14} - 1$
0	0	1	$2^{15} - 1$
0	1	0	$2^{16} - 1$
0	1	1	$2^{17} - 1$
1	0	0	$2^{18} - 1$
1	0	1	$2^{19} - 1$
1	1	0	$2^{20} - 1$
1	1	1	$2^{21} - 1$

To compute WD Timeout, the following formula is applied:

$$FTime-Out = \frac{F_{osc}}{6 \times 2^{WDX2 \wedge X2}(2^{14} \times 2^{Svalue})}$$

Note: Svalue represents the decimal value of (S2 S1 S0)

Find Hereafter computed Timeout values for f_{OSC}XTAL = 12 MHz in X1 mode

Table 51. Timeout Computation

S2	S1	S0	f_{osc}=12 MHz	f_{osc}=16MHz	f_{osc}=20 MHz
0	0	0	16.38 ms	12.28 ms	9.82 ms
0	0	1	32.77 ms	24.57 ms	19.66 ms
0	1	0	65.54 ms	49.14 ms	39.32 ms
0	1	1	131.07 ms	98.28 ms	78.64 ms
1	0	0	262.14 ms	196.56 ms	157.28 ms
1	0	1	524.29 ms	393.12 ms	314.56 ms
1	1	0	1.05 s	786.24 ms	629.12 ms
1	1	1	2.10 s	1.57 s	1.25 s

Watchdog Timer During Power-down Mode and Idle

In Power-down mode the oscillator stops, which means the WDT also stops. While in Power-down mode, the user does not need to service the WDT. There are 2 methods of exiting Power-down mode: by a hardware reset or via a level activated external interrupt which is enabled prior to entering Power-down mode. When Power-down is exited with hardware reset, the watchdog is disabled. Exiting Power-down with an interrupt is significantly different. The interrupt shall be held low long enough for the oscillator to stabilize. When the interrupt is brought high, the interrupt is serviced. To prevent the WDT from resetting the device while the interrupt pin is held low, the WDT is not started until the interrupt is pulled high. It is suggested that the WDT be reset during the interrupt service for the interrupt used to exit Power-down.

To ensure that the WDT does not overflow within a few states of exiting powerdown, it is best to reset the WDT just before entering powerdown.

In the Idle mode, the oscillator continues to run. To prevent the WDT from resetting T89C51CC02 while in Idle mode, the user should always set up a timer that will periodically exit Idle, service the WDT, and re-enter Idle mode.

CAN Controller

The CAN Controller provides all the features required to implement the serial communication protocol CAN as defined by BOSCH GmbH. The CAN specification as referred to by ISO/11898 (2.0A & 2.0B) for high speed and ISO/11519-2 for low speed. The CAN Controller is able to handle all types of frames (Data, Remote, Error and Overload) and achieves a bitrate of 1-Mbit/s at 8 MHz[1] Crystal frequency in X2 Mode.

Note: 1. At BRP = 1 sampling point will be fixed.

CAN Protocol

The CAN protocol is an international standard defined in the ISO 11898 for high speed and ISO 11519-2 for low speed.

Principles

CAN is based on a broadcast communication mechanism. This broadcast communication is achieved by using a message oriented transmission protocol. These messages are identified by using a message identifier. Such a message identifier has to be unique within the whole network and it defines not only the content but also the priority of the message.

The priority at which a message is transmitted compared to another less urgent message is specified by the identifier of each message. The priorities are laid down during system design in the form of corresponding binary values and cannot be changed dynamically. The identifier with the lowest binary number has the highest priority.

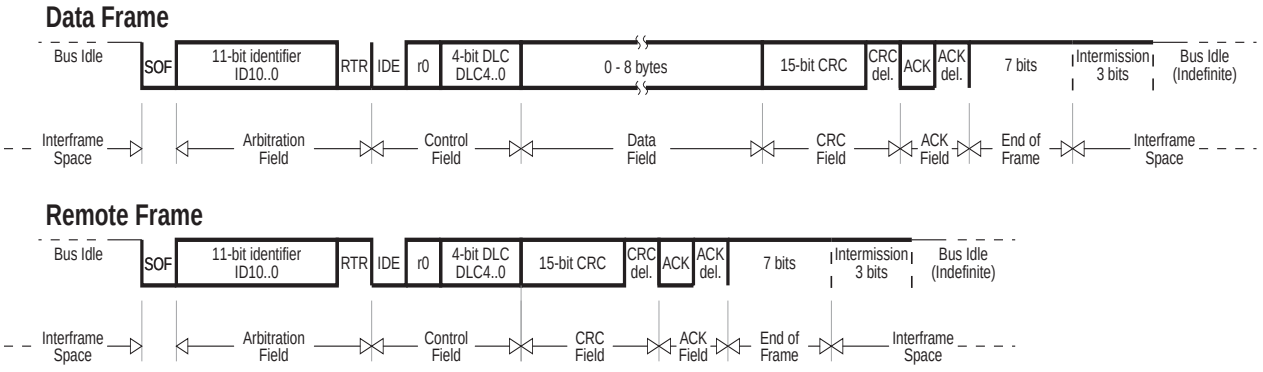
Bus access conflicts are resolved by bit-wise arbitration on the identifiers involved by each node observing the bus level bit for bit. This happens in accordance with the "wired and" mechanism, by which the dominant state overwrites the recessive state. The competition for bus allocation is lost by all nodes with recessive transmission and dominant observation. All the "losers" automatically become receivers of the message with the highest priority and do not re-attempt transmission until the bus is available again.

Message Formats

The CAN protocol supports two message frame formats, the only essential difference being in the length of the identifier. The CAN standard frame, also known as CAN 2.0 A, supports a length of 11 bits for the identifier, and the CAN extended frame, also known as CAN 2.0 B, supports a length of 29 bits for the identifier.

Can Standard Frame

Figure 32. CAN Standard Frames

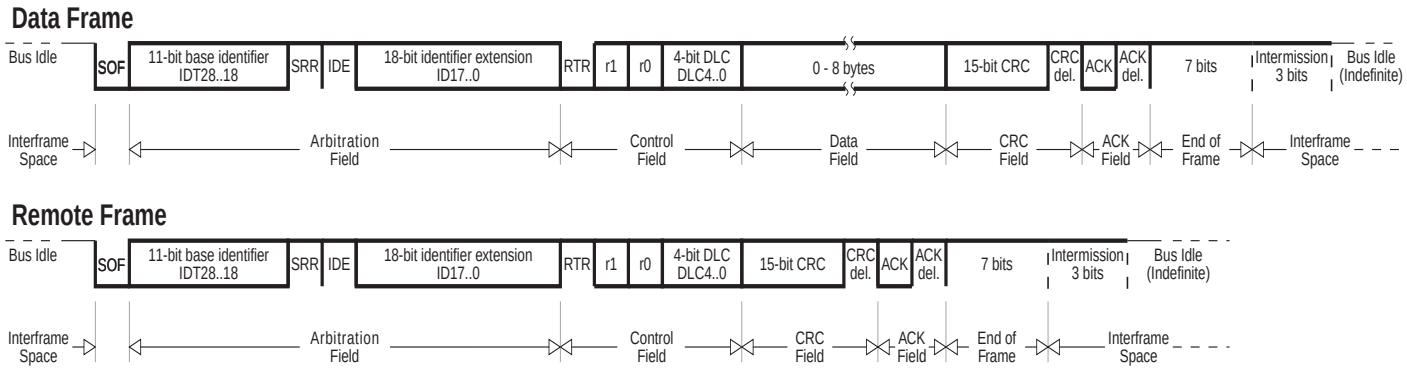


A message in the CAN standard frame format begins with the "Start Of Frame (SOF)", this is followed by the "Arbitration field" which consist of the identifier and the "Remote Transmission Request (RTR)" bit used to distinguish between the data frame and the data request frame called remote frame. The following "Control field" contains the "IDentifier Extension (IDE)" bit and the "Data Length Code (DLC)" used to indicate the

number of following data bytes in the "Data field". In a remote frame, the DLC contains the number of requested data bytes. The "Data field" that follows can hold up to 8 data bytes. The frame integrity is guaranteed by the following "Cyclic Redundant Check (CRC)" sum. The "ACKnowledge (ACK) field" compromises the ACK slot and the ACK delimiter. The bit in the ACK slot is sent as a recessive bit and is overwritten as a dominant bit by the receivers which have at this time received the data correctly. Correct messages are acknowledged by the receivers regardless of the result of the acceptance test. The end of the message is indicated by "End Of Frame (EOF)". The "Intermission Frame Space (IFS)" is the minimum number of bits separating consecutive messages. If there is no following bus access by any node, the bus remains idle.

CAN Extended Frame

Figure 33. CAN Extended Frames



A message in the CAN extended frame format is likely the same as a message in CAN standard frame format. The difference is the length of the identifier used. The identifier is made up of the existing 11-bit identifier (base identifier) and an 18-bit extension (identifier extension). The distinction between CAN standard frame format and CAN extended frame format is made by using the IDE bit which is transmitted as dominant in case of a frame in CAN standard frame format, and transmitted as recessive in the other case.

Format Co-existence

As the two formats have to co-exist on one bus, it is laid down which message has higher priority on the bus in the case of bus access collision with different formats and the same identifier / base identifier: The message in CAN standard frame format always has priority over the message in extended format.

There are three different types of CAN modules available:

- 2.0A - Considers 29 bit ID as an error
- 2.0B Passive - Ignores 29 bit ID messages
- 2.0B Active - Handles both 11 and 29 bit ID Messages

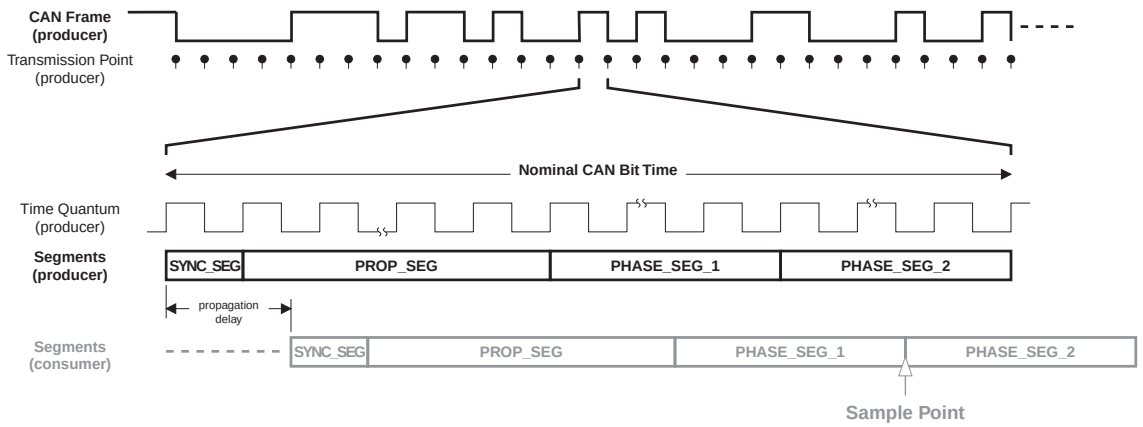
Bit Timing

To ensure correct sampling up to the last bit, a CAN node needs to re-synchronize throughout the entire frame. This is done at the beginning of each message with the falling edge SOF and on each recessive to dominant edge.

Bit Construction

One CAN bit time is specified as four non-overlapping time segments. Each segment is constructed from an integer multiple of the Time Quantum. The Time Quantum or TQ is the smallest discrete timing resolution used by a CAN node.

Figure 34. CAN Bit Construction



Synchronization Segment

The first segment is used to synchronize the various bus nodes.

On transmission, at the start of this segment, the current bit level is output. If there is a bit state change between the previous bit and the current bit, then the bus state change is expected to occur within this segment by the receiving nodes.

Propagation Time Segment

This segment is used to compensate for signal delays across the network.

This is necessary to compensate for signal propagation delays on the bus line and through the transceivers of the bus nodes.

Phase Segment 1

Phase Segment 1 is used to compensate for edge phase errors.

This segment may be lengthened during resynchronization.

Sample Point

The sample point is the point of time at which the bus level is read and interpreted as the value of the respective bit. Its location is at the end of Phase Segment 1 (between the two Phase Segments).

Phase Segment 2

This segment is also used to compensate for edge phase errors.

This segment may be shortened during resynchronization, but the length has to be at least as long as the information processing time and may not be more than the length of Phase Segment 1.

Information Processing Time

It is the time required for the logic to determine the bit level of a sampled bit.

The Information processing Time begins at the sample point, is measured in TQ and is fixed at 2 TQ for the Atmel CAN. Since Phase Segment 2 also begins at the sample point and is the last segment in the bit time, Phase Segment 2 minimum shall not be less than the Information processing Time.

Bit Lengthening

As a result of resynchronization, Phase Segment 1 may be lengthened or Phase Segment 2 may be shortened to compensate for oscillator tolerances. If, for example, the transmitter oscillator is slower than the receiver oscillator, the next falling edge used for resynchronization may be delayed. So Phase Segment 1 is lengthened in order to adjust the sample point and the end of the bit time.

Bit Shortening

If, on the other hand, the transmitter oscillator is faster than the receiver one, the next falling edge used for resynchronization may be too early. So Phase Segment 2 in bit N is shortened in order to adjust the sample point for bit N+1 and the end of the bit time

Synchronization Jump Width

The limit to the amount of lengthening or shortening of the Phase Segments is set by the Resynchronization Jump Width.

This segment may not be longer than Phase Segment 2.

Programming the Sample Point

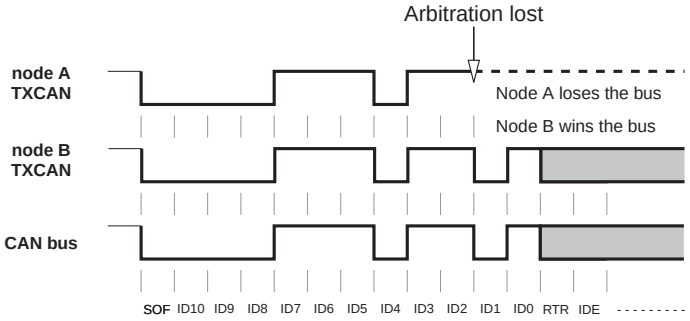
Programming of the sample point allows "tuning" of the characteristics to suit the bus.

Early sampling allows more Time Quanta in the Phase Segment 2 so the Synchronization Jump Width can be programmed to its maximum. This maximum capacity to shorten or lengthen the bit time decreases the sensitivity to node oscillator tolerances, so that lower cost oscillators such as ceramic resonators may be used.

Late sampling allows more Time Quanta in the Propagation Time Segment which allows a poorer bus topology and maximum bus length.

Arbitration

Figure 35. Bus Arbitration



The CAN protocol handles bus accesses according to the concept called “Carrier Sense Multiple Access with Arbitration on Message Priority”.

During transmission, arbitration on the CAN bus can be lost to a competing device with a higher priority CAN Identifier. This arbitration concept avoids collisions of messages whose transmission was started by more than one node simultaneously and makes sure the most important message is sent first without time loss.

The bus access conflict is resolved during the arbitration field mostly over the identifier value. If a data frame and a remote frame with the same identifier are initiated at the same time, the data frame prevails over the remote frame (c.f. RTR bit).

Errors

The CAN protocol signals any errors immediately as they occur. Three error detection mechanisms are implemented at the message level and two at the bit level:

Error at Message Level

- Cyclic Redundancy Check (CRC)
  The CRC safeguards the information in the frame by adding redundant check bits at the transmission end. At the receiver these bits are re-computed and tested against the received bits. If they do not agree there has been a CRC error.
- Frame Check
  This mechanism verifies the structure of the transmitted frame by checking the bit

fields against the fixed format and the frame size. Errors detected by frame checks are designated "format errors".

- ACK Errors
  As already mentioned frames received are acknowledged by all receivers through positive acknowledgement. If no acknowledgement is received by the transmitter of the message an ACK error is indicated.

Error at Bit Level

- Monitoring
  The ability of the transmitter to detect errors is based on the monitoring of bus signals. Each node which transmits also observes the bus level and thus detects differences between the bit sent and the bit received. This permits reliable detection of global errors and errors local to the transmitter.
- Bit Stuffing
  The coding of the individual bits is tested at bit level. The bit representation used by CAN is "Non Return to Zero (NRZ)" coding, which guarantees maximum efficiency in bit coding. The synchronization edges are generated by means of bit stuffing.

Error Signalling

If one or more errors are discovered by at least one node using the above mechanisms, the current transmission is aborted by sending an "error flag". This prevents other nodes accepting the message and thus ensures the consistency of data throughout the network. After transmission of an erroneous message that has been aborted, the sender automatically re-attempts transmission.

CAN Controller Description

The CAN controller accesses are made through SFR.
Several operations are possible by SFR:

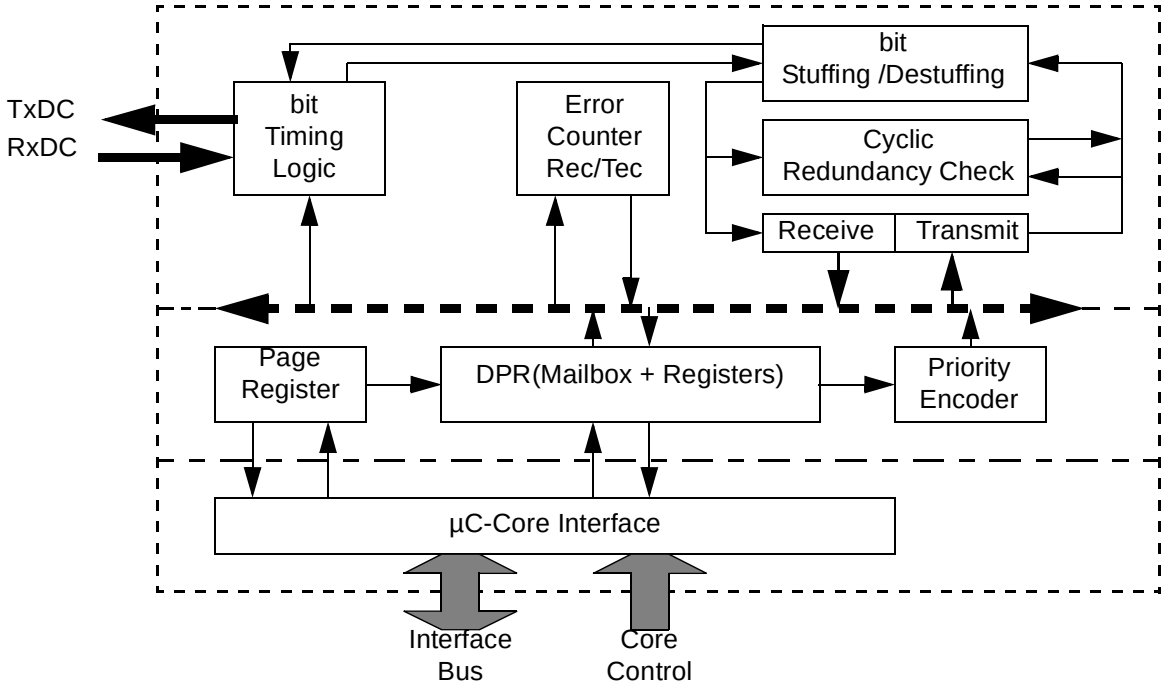
- arithmetic and logic operations, transfers and program control (SFR is accessible by direct addressing).
- 4 independent message objects are implemented, a pagination system manages their accesses.

Any message object can be programmed in a reception buffer block (even non-consecutive buffers). For the reception of defined messages one or several receiver message objects can be masked without participating in the buffer feature. An IT is generated when the buffer is full. The frames following the buffer-full interrupt will not be taken into account until at least one of the buffer message objects is re-enabled in reception. Higher priority of a message object for reception or transmission is given to the lower message object number.

The programmable 16-bit Timer (CANTIMER) is used to stamp each received and sent message in the CANSTMP register. This timer starts counting as soon as the CAN controller is enabled by the ENA bit in the CANGCON register.

The Time Trigger Communication (TTC) protocol is supported by the T89C51CC02.

Figure 36. CAN Controller Block Diagram

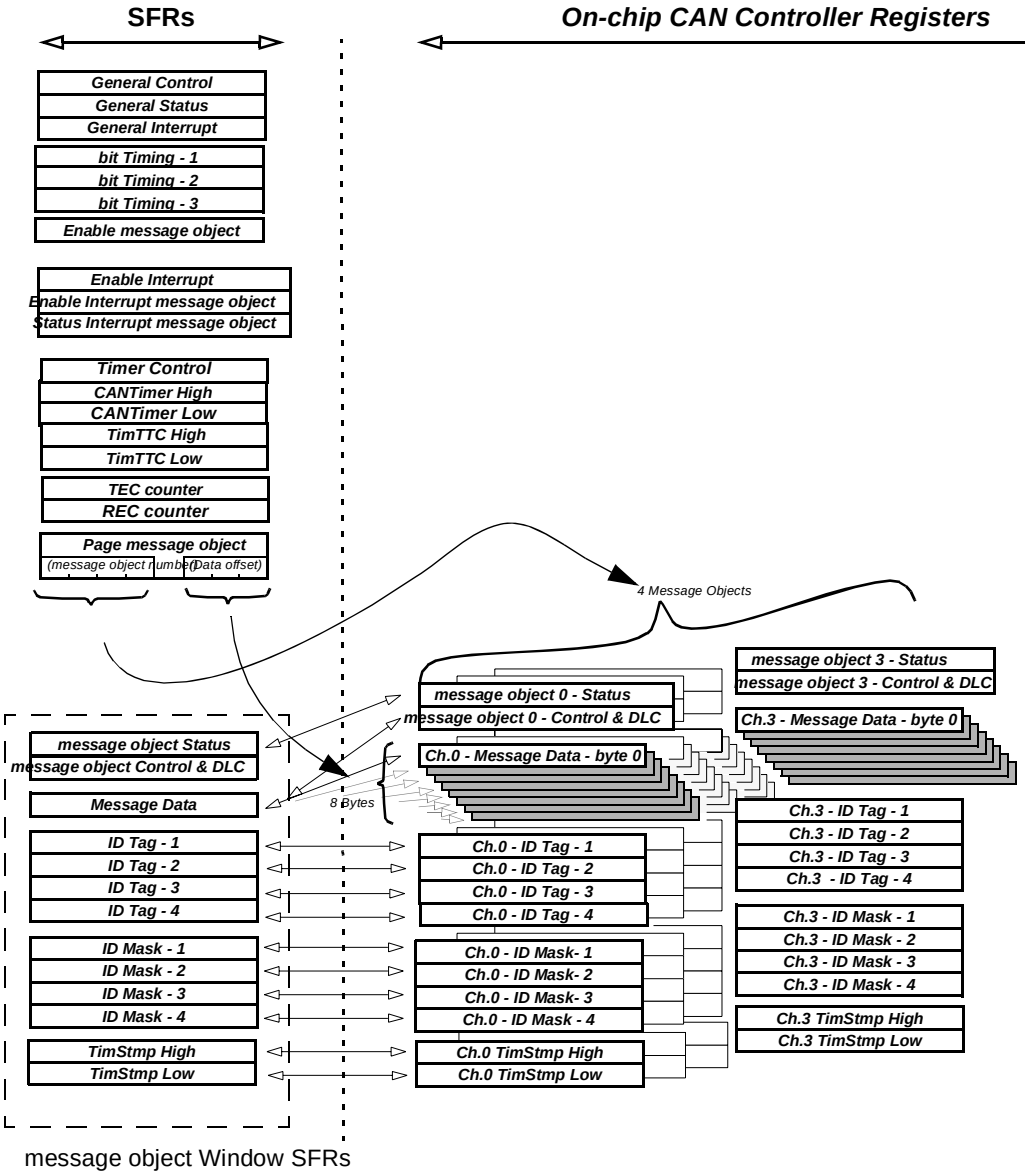


CAN Controller Mailbox and Registers Organization

The pagination allows management of the 91 registers including 80(4 x 20) Bytes of mailbox via 32 SFRs.

All actions on the message object window SFRs apply to the corresponding message object registers pointed by the message object number find in the Page message object register (CANPAGE) as illustrate in Figure 37.

Figure 37. CAN Controller Memory Organization



Working on Message Objects

The Page message object register (CANPAGE) is used to select one of the 4 message objects. Then, message object Control (CANCONCH) and message object Status (CANSTCH) are available for this selected message object number in the corresponding SFRs. A single register (CANMSG) is used for the message. The mailbox pointer is managed by the Page message object register with an auto-incrementation at the end of each access. The range of this counter is 8.
Note that the maibox is a pure RAM, dedicated to one message object, without overlap. In most cases, it is not necessary to transfer the received message into the standard memory. The message to be transmitted can be built directly in the maibox. Most calculations or tests can be executed in the mailbox area which provide quicker access.

CAN Controller Management

In order to enable the CAN Controller correctly the following registers have to be initialized:

- General Control (CANGCON),
- bit Timing (CANBT 1, 2 & 3),
- And for each page of 15 message objects:
  - Message object Control (CANCONCH),
  - Message object Status (CANSTCH).

During operation, the CAN Enable message object registers (CANEN) gives a fast overview of the message objects availability.

The CAN messages can be handled by interrupt or polling modes.

A message object can be configured as follows:

- Transmit message object
- Receive message object
- Receive buffer message object
- Disable

This configuration is made in the CONCH field of the CANCONCH register (See Table 54).

When a message object is configured, the corresponding ENCH bit of CANEN register is set.

Table 54. Configuration for CONCH1:2

CONCH 1	CONCH 2	Type of Message Object
0	0	Disable
0	1	Transmitter
1	0	Receiver
1	1	Receiver buffer

When a Transmitter or Receiver action of a message object is completed, the corresponding ENCH bit of the CANEN register is cleared. In order to re-enable the message object, it is necessary to re-write the configuration in CANCONCH register.

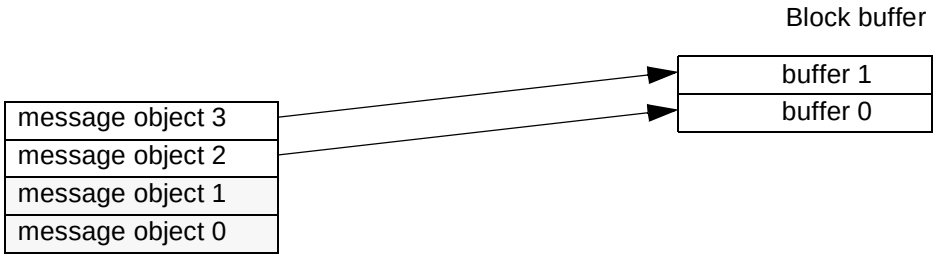
Non-consecutive message objects can be used for all three types of message objects (Transmitter, Receiver and Receiver buffer).

Buffer Mode

Any message object can be used to define one buffer, including non-consecutive message objects, and with no limitation in number of message objects used up to 4.

Each message object of the buffer must be initialized CONCH2 = 1 and CONCH1 = 1;

Figure 38. Buffer Mode



The same acceptance filter must be defined for each message objects of the buffer. When there is no mask on the identifier or the IDE, all messages are accepted.

A received frame will always be stored in the lowest free message object.

When the flag RxOk is set on one of the buffer message objects, this message object can then be read by the application. This flag must then be cleared by the software and the message object re-enabled in buffer reception in order to free the message object.

The OVRBUF flag in the CANGIT register is set when the buffer is full. This flag can generate an interrupt.

The frames following the buffer-full interrupt will not be stored and no status will be overwritten in the CANSTCH registers involved in the buffer until at least one of the buffer message objects is re-enabled in reception.

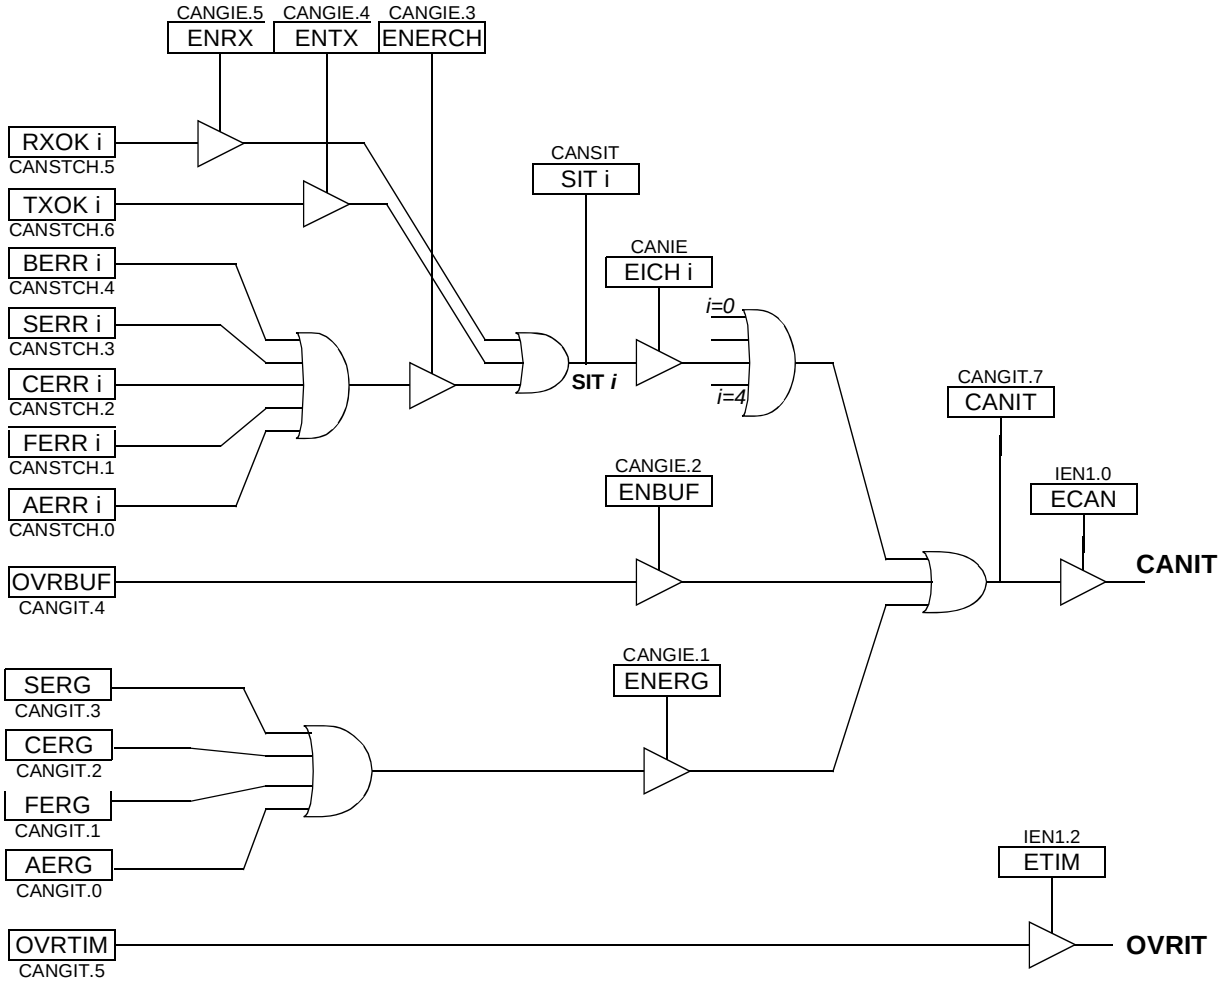
This flag must be cleared by the software in order to acknowledge the interrupt.

IT CAN Management

The different interrupts are:

- Transmission interrupt
- Reception interrupt
- Interrupt on error (bit error, stuff error, crc error, form error, acknowledge error)
- Interrupt when Buffer receive is full
- Interrupt on overrun of CAN Timer

Figure 39. CAN Controller Interrupt Structure



To enable a transmission interrupt:

- Enable General CAN IT in the interrupt system register
- Enable interrupt by message object, EICHi
- Enable transmission interrupt, ENTX

To enable a reception interrupt:

- Enable General CAN IT in the interrupt system register
- Enable interrupt by message object, EICHi
- Enable reception interrupt, ENRX

To enable an interrupt on message object error:

- Enable General CAN IT in the interrupt system register
- Enable interrupt by message object, EICHi
- Enable interrupt on error, ENERCH

To enable an interrupt on general error:

- Enable General CAN IT in the interrupt system register
- Enable interrupt on error, ENERG

To enable an interrupt on Buffer-full condition:

- Enable General CAN IT in the interrupt system register
- Enable interrupt on Buffer full, ENBUF

To enable an interrupt when Timer overruns:

- Enable Overrun IT in the interrupt system register

When an interrupt occurs, the corresponding message object bit is set in the SIT register.

To acknowledge an interrupt, the corresponding CANSTCH bits (RXOK, TXOK,...) or CANGIT bits (OVRTIM, OVRBUF,...), must be cleared by the software application.

When the CAN node is in transmission and detects a Form Error in its frame, a bit Error will also be raised. Consequently, two consecutive interrupts can occur, both due to the same error.

When a message object error occurs and is set in CANSTCH register, no general error are set in CANGIE register.

Bit Timing and Baud Rate

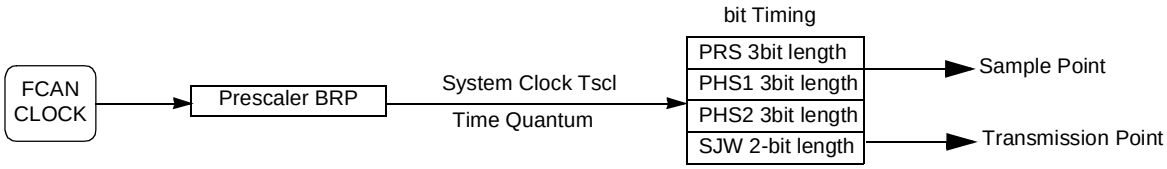
FSM's (Finite State Machine) of the CAN channel need to be synchronous to the time quantum. So, the input clock for bit timing is the clock used into CAN channel FSM's.

Field and segment abbreviations:

- BRP: Baud Rate Prescaler.
- TQ: Time Quantum (output of Baud Rate Prescaler).
- SYNS: SYNchronization Segment is 1 TQ long.
- PRS: PRopagation time Segment is programmable to be 1, 2, ..., 8 TQ long.
- PHS1: PHase Segment 1 is programmable to be 1, 2, ..., 8 TQ long.
- PHS2: PHase Segment 2 is programmable to be superior or eual to the Information Processing Time and inferior or equal to TPHS1
- INFORMATION PROCESSING TIME is 2 TQ.
- SJW: (Re) Synchronization Jump Width is programmable to be minimum of PHS1 and 4.

The total number of TQ in a bit time has to be programmed at least from 8 to 25.

Figure 40. Sample and Transmission Point



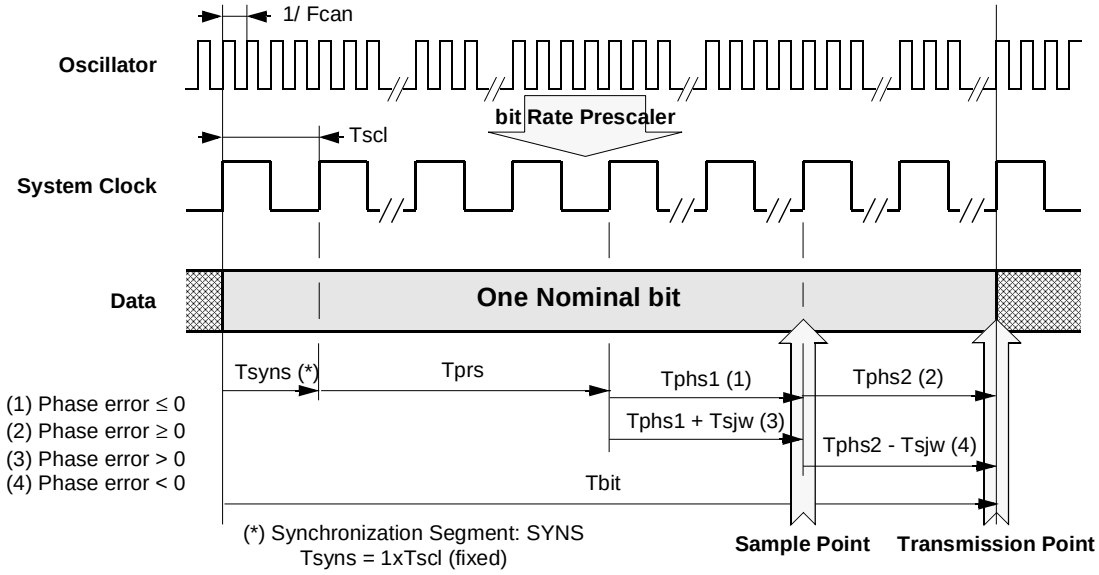
The baud rate selection is made by Tbit calculation:

Tbit = Tsyns + Tprs + Tphs1 + Tphs2

1. Tsyns = Tscl = (BRP[5..0]+ 1)/Fcan = 1TQ
2. Tprs = (1 to 8) * Tscl = (PRS[2..0]+ 1) * Tscl
3. Tphs1 = (1 to 8) * Tscl = (PHS1[2..0]+ 1) * Tscl
4. Tphs2 = (1 to 8) * Tscl = (PHS2[2..0]+ 1) * Tscl
   Tphs2 = Max of (Tphs1 and 2TQ)
5. Tsjw = (1 to 4) * Tscl = (SJW[1..0]+ 1) * Tscl

The total number of Tscl (Time Quanta) in a bit time must be comprised between 8 to 25.

Figure 41. General Structure of a bit Period



Tbit calculation: $Tbit = Tsyns + Tprs + Tphs1 + Tphs2$

example of bit timing determination for CAN baudrate of 500 kbit/s:
F_{OSC} = 12 MHz in X1 mode => FCAN = 6MHz

Verify that the CAN baud rate you want is an integer division of FCAN clock.
FCAN/CANbaudrate = 6 MHz/500 kHz = 12
The time quanta TQ must be comprised between 8 and 25: TQ = 12 and **BRP = 0**

Define the various timing parameters: Tbit = Tsyns + Tprs + Tphs1 + Tphs2 = 12TQ
Tsyns = 1TQ and Tsjw =1TQ => **SJW = 0**
If we chose a sample point at 66.6% => Tphs2 = 4TQ => **PHS2 = 3**
Tbit = 12 = 4 + 1 + Tphs1 + Tprs, let us choose Tprs = 3 Tphs1 = 4
PHS1 = 3 and **PRS = 2**

BRP = 0 so CANBT1 = 00h
SJW = 0 and PRS = 2 so CANBT2 = 04h
PHS2 = 3 and PHS1 = 3 so CANBT3 = 36h

Fault Confinement

With respect to fault confinement, a unit may be in one of the three following status:

- Error active
- Error passive
- Bus off

An error active unit takes part in bus communication and can send an active error frame when the CAN macro detects an error.

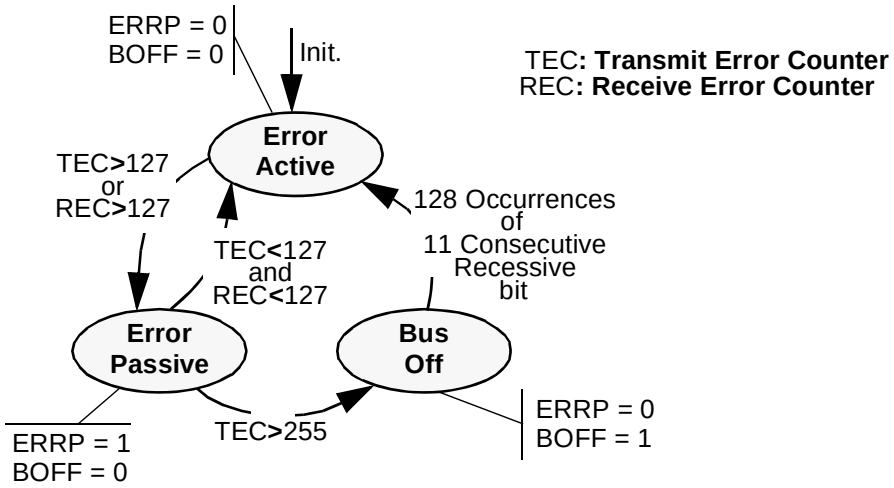
An error passive unit cannot send an active error frame. It takes part in bus communication, but when an error is detected, a passive error frame is sent. Also, after a transmission, an error passive unit will wait before initiating further transmission.

A bus off unit is not allowed to have any influence on the bus.

For fault confinement, two error counters (TEC and REC) are implemented.

See CAN Specification for details on Fault confinement.

Figure 42. Line Error Mode



Acceptance Filter

Upon a reception hit (i.e., a good comparison between the ID+RTR+RB+IDE received and an ID+RTR+RB+IDE specified while taking the comparison mask into account) the ID+RTR+RB+IDE received are written over the ID TAG Registers.

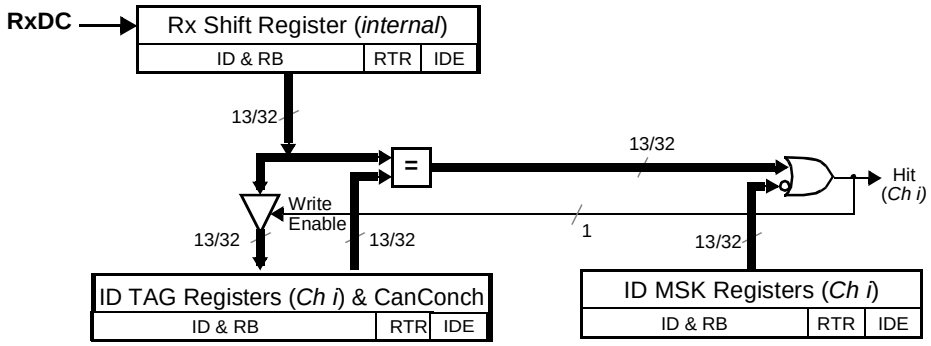
ID => IDT0-29

RTR => RTRTAG

RB => RB0-1TAG

IDE => IDE in CANCONCH register

Figure 43. Acceptance Filter Block Diagram

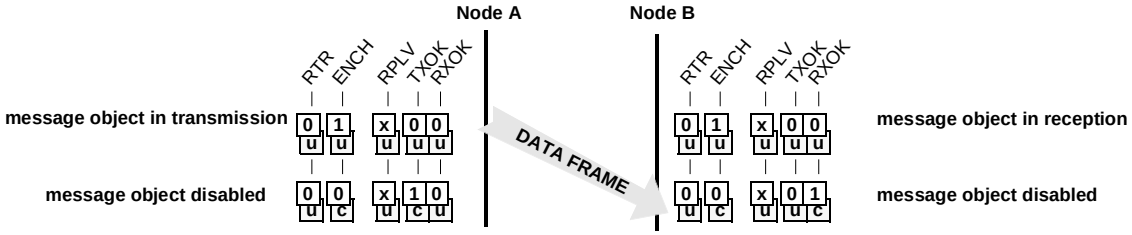


```
example:
To accept only ID = 318h in part A.
ID MSK = 111 1111 1111 b
ID TAG = 011 0001 1000 b
```

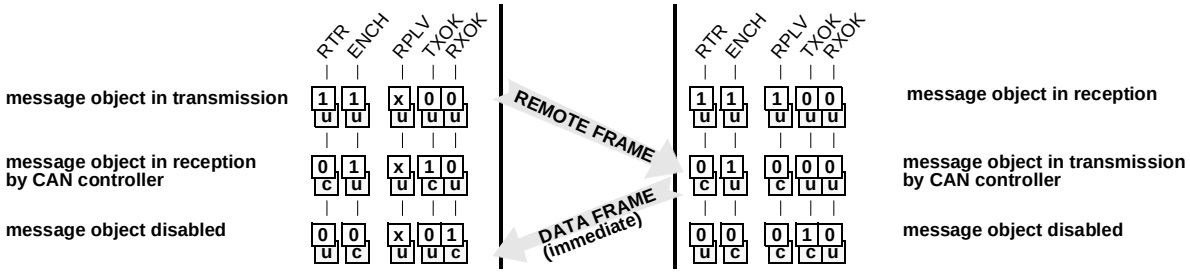
Data and Remote Frame

Description of the different steps for:

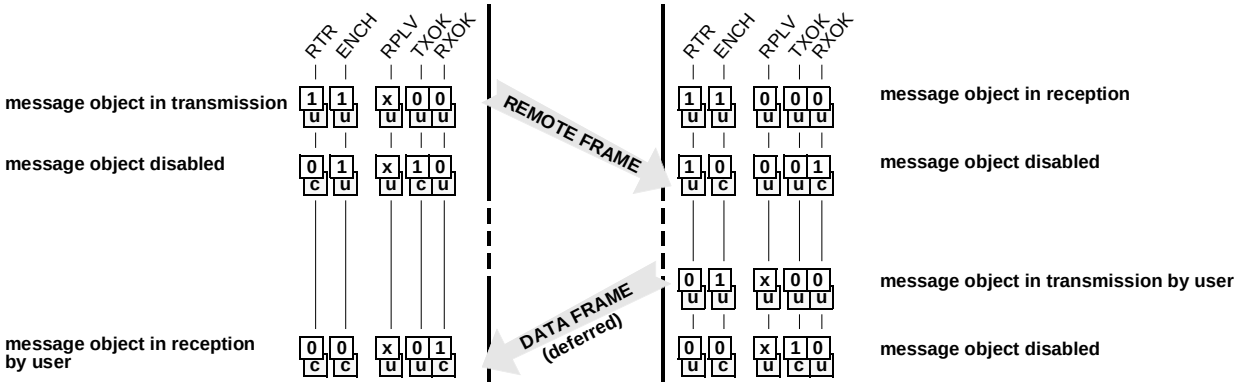
- Data frame



- Remote frame, with automatic reply



- Remote frame



i u : modified by user i c : modified by CAN

Time Trigger Communication (TTC) and Message Stamping

The T89C51CC02 has a programmable 16-bit Timer (CANTIMH&CANTIML) for message stamp and TTC.

This CAN Timer starts after the CAN controller is enabled by the ENA bit in the CANGCON register.

Two modes in the timer are implemented:

- Time Trigger Communication:
  - Capture of this timer value in the CANTTCH & CANTTCL registers on Start Of Frame (SOF) or End Of Frame (EOF), depending on the SYNCTTC bit in the CANGCON register, when the network is configured in TTC by the TTC bit in the CANGCON register.

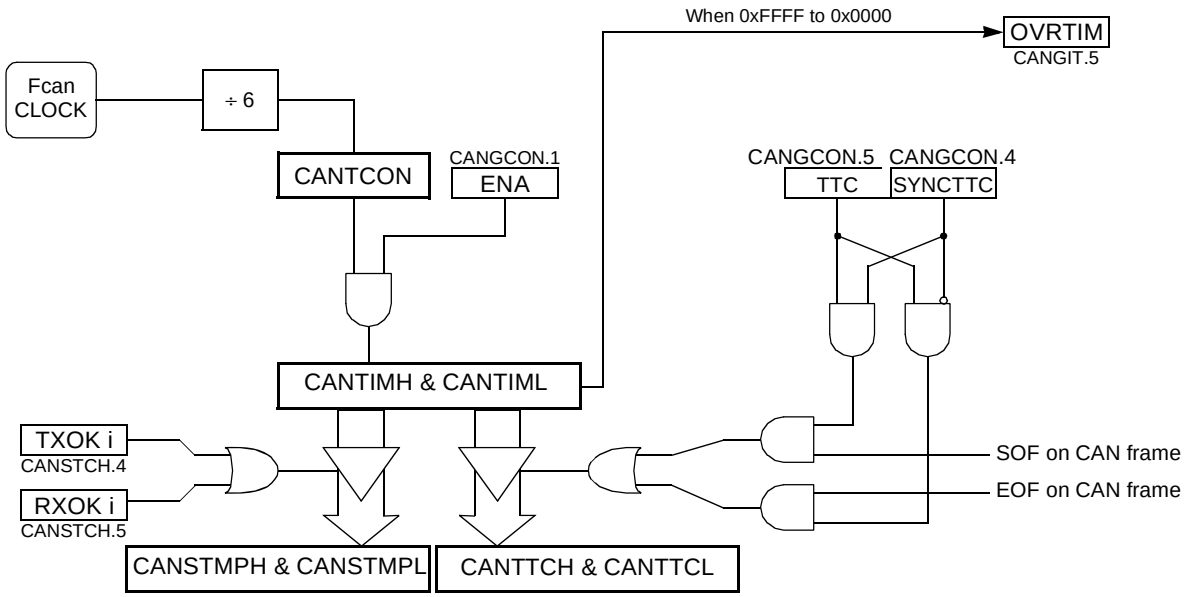
Note: In this mode, CAN ***only sends the frame once, even if an error occurs***.

- Message Stamping
  - Capture of this timer value in the CANSTMPH & CANSTMPL registers of the message object which received or sent the frame.
  - All messages can be stamps.
  - The stamping of a received frame occurs when the RxOk flag is set.
  - The stamping of a sent frame occurs when the TxOk flag is set.

The CAN Timer works in a roll-over from FFFFh to 0000h which serves as a time base.

When the timer roll-over from FFFFh to 0000h, an interrupt is generated if the ETIM bit in the interrupt enable register IEN1 is set.

Figure 44. Block Diagram of CAN Timer



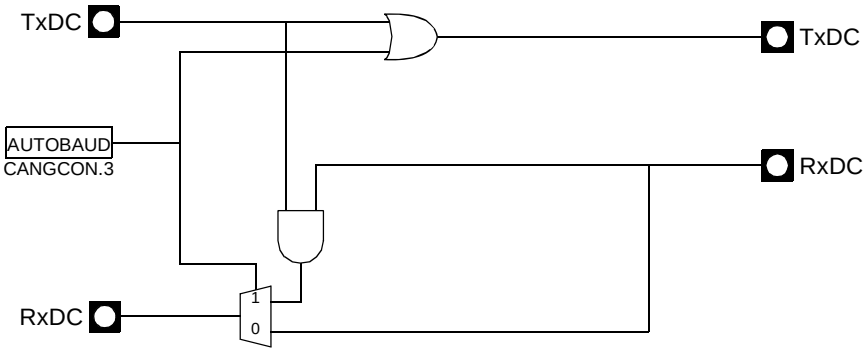
CAN Autobaud and Listening Mode

To activate the Autobaud feature, the AUTOBAUD bit in the CANGCON register must be set. In this mode, the CAN controller is only listening to the line without acknowledging the received messages. It cannot send any message. The error flags are updated. The bit timing can be adjusted until no error occurs (good configuration find).

In this mode, the error counters are frozen.

To go back to the standard mode, the AUTOBAUD bit must be cleared.

Figure 45. Autobaud Mode



Routine Examples

```
1. Init of CAN macro
// Reset the CAN macro
 CANGCON = 01h;
// Disable CAN interrupts
 ECAN   = 0;
 ETIM   = 0;
// Init the Mailbox
 for num_page =0; num_page <4; num_page++
    {
    CANPAGE = num_channel << 4;
    CANCONCH = 00h
    CANSTCH = 00h;
    CANIDT1 = 00h;
    CANIDT2 = 00h;
    CANIDT3 = 00h;
    CANIDT4 = 00h;
    CANIDM1 = 00h;
    CANIDM2 = 00h;
    CANIDM3 = 00h;
    CANIDM4 = 00h;
    for num_data =0; num_data <8; num_data++)
      {
      CANMSG = 00h;
}
}
// Configure the bit timing
 CANBT1 = xxh
 CANBT2 = xxh
 CANBT3 = xxh
```

```
// Enable the CAN macro
 CANGCON = 02h
2. Configure message object 3 in reception to receive only standard (11bit
identifier) message 100h
// Select the message object 3
 CANPAGE = 30h
// Enable the interrupt on this message object
 CANIE = 08h
// Clear the status and control register
 CANSTCH = 00h
 CANCONCH= 00h
// Init the acceptance filter to accept only message 100h in standard mode
 CANIDT1 = 20h
 CANIDT2 = 00h
 CANIDT3 = 00h
 CANIDT4 = 00h
 CANIDM1 = FFh
 CANIDM2 = FFh
 CANIDM3 = FFh
 CANIDM4 = FFh
// Enable channel in reception
 CANCONCH = 88h // enable reception

Note: to enable the CAN interrupt in reception:
EA = 1
ECAN = 1
CANGIE = 20h
3. Send a message on the message object 0
// Select the message object 0
 CANPAGE = 00h
// Enable the interrupt on this message object
 CANIE = 01h
// Clear the Status register
 CANSTCH = 00h;
// load the identifier to send (ex: 555h)
 CANIDT1 = AAh;
 CANIDT2 = A0h;
// load data to send
 CANMSG = 00h
 CANMSG = 01h
 CANMSG = 02h
 CANMSG = 03h
 CANMSG = 04h
 CANMSG = 05h
 CANMSG = 06h
 CANMSG = 07h
// configure the control register
 CANCONCH = 18h
4. Interrupt routine
// Save the current CANPAGE
```

```
// Find the first message object which generate an interrupt in CANSIT
// Select the corresponding message object

// Analyse the CANSTCH register to identify which kind of interrupt is
generated

// Manage the interrupt

// Clear the status register CANSTCH = 00h;

// if it is not a channel interrupt but a general interrupt
// Manage the general interrupt and clear CANGIT register

// restore the old CANPAGE
```

Table 56. CANGCON Register

CANGCON (S:ABh)
CAN General Control Register

7	6	5	4	3	2	1	0
ABRQ	OVRQ	TTC	SYNCTTC	AUTOBAUD	TEST	ENA	GRES

Bit Number	Bit Mnemonic	Description
7	ABRQ	**Abort Request** Not an auto-resetable bit. A reset of the ENCH bit (message object control & DLC register) is done for each message object. The pending transmission communications are immediately aborted but the on-going communication will be terminated normally, setting the appropriate status flags, TxOk or RxOk.
6	OVRQ	**Overload Frame Request (Initiator)**. Auto-resetable bit. Set to send an overload frame after the next received message. Cleared by the hardware at the beginning of transmission of the overload frame.
5	TTC	**Network in Timer Trigger Communication** set to select node in TTC. clear to disable TTC features.
4	SYNCTTC	**Synchronization of TTC** When this bit is set the TTC timer is caught on the last bit of the End Of Frame. When this bit is clear the TTC timer is caught on the Start Of Frame. This bit is only used in the TTC mode.
3	AUTOBAUD	**AUTOBAUD** set to active listening mode. Clear to disable listening mode
2	TEST	Test mode. The test mode is intended for factory testing and not for customer use.
1	ENA/$\overline{\text{STB}}$	**Enable/Standby CAN Controller** When this bit is set, it enables the CAN controller and its input clock. When this bit is clear, the on-going communication is terminated normally and the CAN controller state of the machine is frozen (the ENCH bit of each message object does not change). In the standby mode, the transmitter constantly provides a recessive level; the receiver is not activated and the input clock is stopped in the CAN controller. During the disable mode, the registers and the mailbox remain accessible. Note that two clock periods are needed to start the CAN controller state of the machine.
0	GRES	**General Reset (Software Reset).** Auto-resetable bit. This reset command is 'ORed' with the hardware reset in order to reset the controller. After a reset, the controller is disabled.

Reset Value = 0000 0000b

Table 57. CANGSTA Register

CANGSTA (S:AAh Read Only)
CAN General Status Register

7	6	5	4	3	2	1	0

Bit Number	Bit Mnemonic	Description
7	-	**Reserved** The values read from this bit is indeterminate. Do not set this bit.
6	OVFG	**Overload frame flag** This status bit is set by the hardware as long as the produced overload frame is sent. This flag does not generate an interrupt
5	-	**Reserved** The values read from this bit is indeterminate. Do not set this bit.
4	TBSY	**Transmitter busy** This status bit is set by the hardware as long as the CAN transmitter generates a frame (remote, data, overload or error frame) or an ack field. This bit is also active during an InterFrame Spacing if a frame must be sent. This flag does not generate an interrupt.
3	RBSY	**Receiver busy** This status bit is set by the hardware as long as the CAN receiver acquires or monitors a frame. This flag does not generate an interrupt.
2	ENFG	**Enable on-chip CAN controller flag** Because an enable/disable command is not effective immediately, this status bit gives the true state of a chosen mode. This flag does not generate an interrupt.
1	BOFF	**Bus off mode** See Figure 42
0	ERRP	**Error passive mode** See Figure 42

Reset Value = x0x0 0000b

Bit Number	Bit Mnemonic	Description
7	CANIT	**General interrupt flag**[1] This status bit is the image of all the CAN controller interrupts sent to the interrupt controller. It can be used in the case of the polling method.
6	-	**Reserved** The values read from this bit is indeterminate. Do not set this bit.
5	OVRTIM	**Overrun CAN Timer** This status bit is set when the CAN timer switches 0xFFFF to 0x0000. If the bit ETIM in the IE1 register is set, an interrupt is generated. Clear this bit in order to reset the interrupt.
4	OVRBUF	**Overrun BUFFER** 0 - no interrupt. 1 - IT turned on This bit is set when the buffer is full. bit resetable by user. See Figure 39.
3	SERG	**Stuff Error General** Detection of more than five consecutive bits with the same polarity. This flag can generate an interrupt. resetable by user.
2	CERG	**CRC Error General** The receiver performs a CRC check on each destuffed received message from the start of frame up to the data field. If this checking does not match with the destuffed CRC field, a CRC error is set. This flag can generate an interrupt. resetable by user.
1	FERG	**Form Error General** The form error results from one or more violations of the fixed form in the following bit fields: CRC delimiter acknowledgment delimiter end_of_frame This flag can generate an interrupt. resetable by user.
0	AERG	**Acknowledgment Error General** No detection of the dominant bit in the acknowledge slot. This flag can generate an interrupt. resetable by user.

Bit Number	Bit Mnemonic	Description
7 - 4	-	**Reserved** The values read from these bits are indeterminate. Do not set these bits.
3 - 0	ENCH3:0	**Enable Message Object** 0 - message object is disabled => the message object is free for a new emission or reception. 1 - message object is enabled. This bit is resetable by re-writing the CANCONCH of the corresponding message object.

Reset Value = xxxx 0000b

Table 63. CANSIT Register
CANSIT (S:BBh Read Only) – CAN Status Interrupt Message Object Registers

7	6	5	4	3	2	1	0
-	-	-	-	SIT3	SIT2	SIT1	SIT0

Bit Number	Bit Mnemonic	Description
7 - 4	-	**Reserved** The values read from these bits are indeterminate. Do not set these bits.
3 - 0	SIT3:0	**Status of Interrupt by Message Object** 0 - no interrupt. 1 - IT turned on. Reset when interrupt condition is cleared by user. SIT3:0 = 0b 0000 1001 -> IT's on message objects 3 & 0. See Figure 39.

Reset Value = xxxx0000b

Table 64. CANIE Register

CANIE (S:C3h) – CAN Enable Interrupt message object Registers

7	6	5	4	3	2	1	0
-	-	-	-	IECH 3	IECH 2	IECH 1	IECH 0

Bit Number	Bit Mnemonic	Description
7 - 4	-	**Reserved** The values read from these bits are indeterminate. Do not set these bits.
3 - 0	IECH3:0	**Enable Interrupt by Message Object** 0 - disable IT. 1 - enable IT. IECH3:0 = 0b 0000 1100 -> Enable IT's of message objects 3 & 2.

Reset Value = xxxx 0000b

Table 65. CANBT1 Register

CANBT1 (S:B4h) – CAN bit Timing Registers 1

7	6	5	4	3	2	1	0
-	BRP 5	BRP 4	BRP 3	BRP 2	BRP 1	BRP 0	-

Bit Number	Bit Mnemonic	Description
7	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
6 - 1	BRP5:0	**Baud Rate Prescaler** **The period of the CAN** controller system clock Tscl is programmable and determines the individual bit timing.(1) $Tscl = \frac{BRP[5..0] + 1}{F_{CAN}}$
0	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.

Note: 1. The CAN controller bit timing registers must be accessed only if the CAN controller is disabled with the ENA bit of the CANGCON register set to 0.
See Figure 41.

No default value after reset.

Table 66. CANBT2 Register

CANBT2 (S:B5h) – CAN bit Timing Registers 2

7	6	5	4	3	2	1	0
-	SJW 1	SJW 0	-	PRS 2	PRS 1	PRS 0	-

Bit Number	Bit Mnemonic	Description
7	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
6 - 5	SJW1:0	**Re-synchronization Jump Width** To compensate for phase shifts between clock oscillators of different bus controllers, the controller must re-synchronize on any relevant signal edge of the current transmission. The synchronization jump width defines the maximum number of clock cycles. A bit period may be shortened or lengthened by a re-synchronization. Tsjw = Tscl x (SJW [1..0] +1)
4	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
3 - 1	PRS2:0	**Programming Time Segment** This part of the bit time is used to compensate for the physical delay times within the network. It is twice the sum of the signal propagation time on the bus line, the input comparator delay and the output driver delay. Tprs = Tscl x (PRS[2..0] + 1)
0	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.

Note: 1. The CAN controller bit timing registers must be accessed only if the CAN controller is disabled with the ENA bit of the CANGCON register set to 0.
See Figure 41.

No default value after reset.

Table 67. CANBT3 Register

CAN bit Timing Registers 3

7	6	5	4	3	2	1	0
-	PHS2 2	PHS2 1	PHS2 0	PHS1 2	PHS1 1	PHS1 0	SMP

Bit Number	Bit Mnemonic	Description
7	-	**Reserved** The value read from this bit is indeterminate. Do not set this bit.
6 - 4	PHS2 2:0	**Phase Segment 2** This phase is used to compensate for phase edge errors. This segment can be shortened by the re-synchronization jump width. Tphs2 = Tscl x (PHS2[2..0] + 1) Phasse segment 2 is the maximum of Phase segment1 and the Information Processing Time (= 2TQ).
3 - 1	PHS1 2:0	**Phase Segment 1** This phase is used to compensate for phase edge errors. This segment can be lengthened by the re-synchronization jump width. Tphs1 = Tscl x (PHS1[2..0] + 1)
0	SMP	**Sample Type** 0 - once, at the sample point. 1 - three times, the threefold sampling of the bus is the sample point and twice over a distance of a 1/2 period of the Tscl. The result corresponds to the majority decision of the three values.

Note: 1. The CAN controller bit timing registers must be accessed only if the CAN controller is disabled with the ENA bit of the CANGCON register set to 0.
See Figure 41.

No default value after reset.

Table 68. CANPAGE Register
CANPAGE (S:B1h) – CAN Message Object Page Register

7	6	5	4	3	2	1	0
-	-	CHNB 1	CHNB 0	AINC	INDX2	INDX1	INDX0

Bit Number	Bit Mnemonic	Description
7 - 6	-	**Reserved** The values read from these bits are indeterminate. Do not set these bits.
5 - 4	CHNB3:0	**Selection of Message Object Number** The available numbers are: 0 to 3(See Figure 37).
3	AINC	**Auto Increment of the Index (Active Low)** 0 - auto-increment of the index (default value). 1 - non-auto-increment of the index.
2 - 0	INDX2:0	**Index** Byte location of the data field for the defined message object (See Figure 37).

Reset Value = xx00 0000b

Table 69. CANCONCH Register
CANCONCH (S:B3h) – CAN Message Object Control and DLC Register

7	6	5	4	3	2	1	0
CONCH 1	CONCH 0	RPLV	IDE	DLC 3	DLC 2	DLC 1	DLC 0

Bit Number	Bit Mnemonic	Description
7 - 6	CONCH1:0	**Configuration of Message Object** **CONCH1** **CONCH0** 0 0: disable 0 1: Launch transmission 1 0: Enable Reception 1 1: Enable Reception Buffer NOTE: The user must re-write the configuration to enable the corresponding bit in the CANEN1:2 registers.
5	RPLV	**Reply valid** Used in the automatic reply mode after receiving a remote frame 0 - reply not ready. 1 - reply ready & valid.
4	IDE	**Identifier Extension** 0 - CAN standard rev 2.0 A (ident = 11 bits). 1 - CAN standard rev 2.0 B (ident = 29 bits).
3 - 0	DLC3:0	**Data Length Code** Number of Bytes in the data field of the message. The range of DLC is from 0 up to 8. This value is updated when a frame is received (data or remote frame). If the expected DLC differs from the incoming DLC, a warning appears in the CANSTCH register.

No default value after reset

Table 70. CANSTCH Register

CANSTCH (S:B2h) – CAN Message Object Status Register

7	6	5	4	3	2	1	0
DLCW	TXOK	RXOK	BERR	SERR	CERR	FERR	AERR

Bit Number	Bit Mnemonic	Description
7	DLCW	**Data Length Code Warning** The incoming message does not have the DLC expected. Whatever the frame type, the DLC field of the CANCONCH register is updated by the received DLC.
6	TXOK	**Transmit OK** The communication enabled by transmission is completed. When the controller is ready to send a frame, if two or more message objects are enabled as producers, the lower index message object (0 to 13) is supplied first. Must be cleared by software. This flag can generate an interrupt.
5	RXOK	**Receive OK** The communication enabled by reception is completed. In the case of two or more message object reception hits, the lower index message object (0 to 13) is updated first. Must be cleared by software. This flag can generate an interrupt.
4	BERR	**bit Error (only in transmission)** The bit value monitored is different from the bit value sent. Exceptions: the monitored recessive bit sent as a dominant bit during the arbitration field and the acknowledge slot detecting a dominant bit during the sending of an error frame. Must be cleared by software. This flag can generate an interrupt.
3	SERR	**Stuff Error** Detection of more than five consecutive bits with the same polarity. Must be cleared by software. This flag can generate an interrupt.
2	CERR	**CRC Error** The receiver performs a CRC check on each destuffed received message from the start of frame up to the data field. If this checking does not match with the destuffed CRC field, a CRC error is set. Must be cleared by software. This flag can generate an interrupt.
1	FERR	**Form Error** The form error results from one or more violations of the fixed form in the following bit fields: CRC delimiter acknowledgment delimiter end_of_frame Must be cleared by software. This flag can generate an interrupt.
0	AERR	**Acknowledgment Error** No detection of the dominant bit in the acknowledge slot. Must be cleared by software. This flag can generate an interrupt.

Programmable Counter Array (PCA)

The PCA provides more timing capabilities with less CPU intervention than the standard timer/counters. Its advantages include reduced software overhead and improved accuracy. The PCA consists of a dedicated timer/counter which serves as the time base for an array of two compare/capture modules. Its clock input can be programmed to count any of the following signals:

- PCA clock frequency/6 (See “clock” section)
- PCA clock frequency/2
- Timer 0 overflow
- External input on ECI (P1.2)

Each compare/capture modules can be programmed in any one of the following modes:

- Rising and/or falling edge capture,
- Software timer
- High-speed output
- Pulse width modulator

When the compare/capture modules are programmed in capture mode, software timer, or high speed output mode, an interrupt can be generated when the module executes its function. Both modules and the PCA timer overflow share one interrupt vector.

The PCA timer/counter and compare/capture modules share Port 1 for external I/Os. These pins are listed below. If the pin is not used for the PCA, it can still be used for standard I/O.

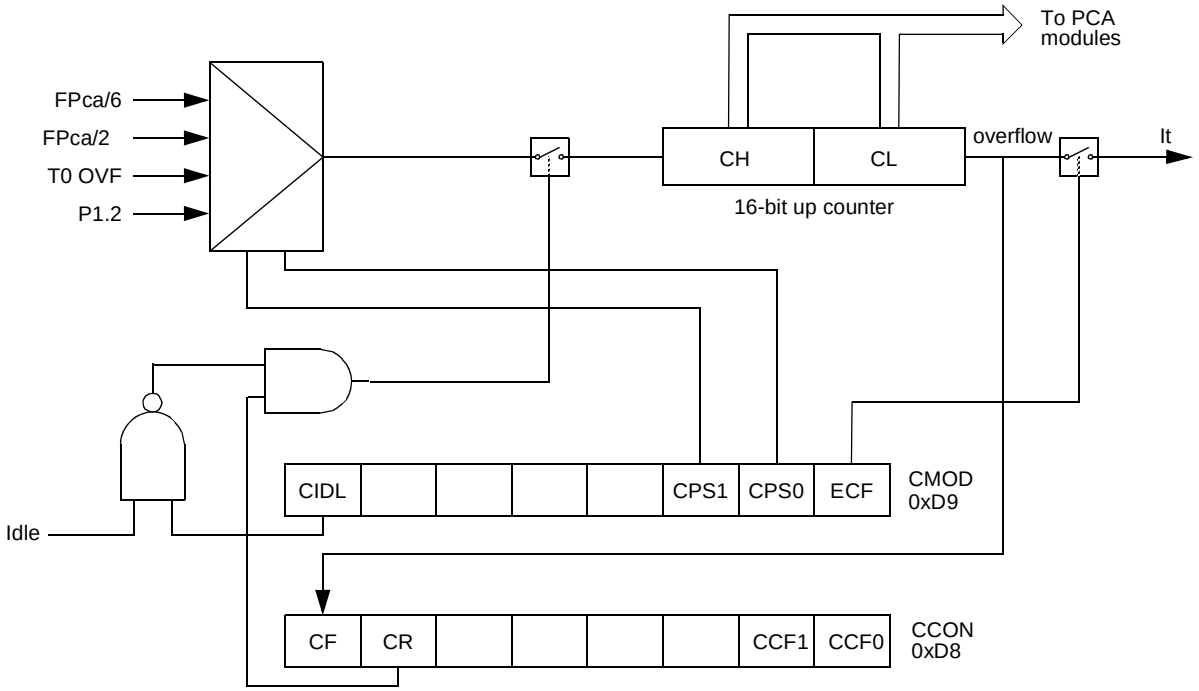
PCA Component	External I/O Pin
16-bit Counter	P1.2/ECI
16-bit Module 0	P1.3/CEX0
16-bit Module 1	P1.4/CEX1

PCA Timer

The PCA timer is a common time base for both modules (See Figure 9). The timer count source is determined from the CPS1 and CPS0 bits in the **CMOD SFR** (See Table 8) and can be programmed to run at:

- 1/6 the PCA clock frequency.
- 1/2 the PCA clock frequency.
- The Timer 0 overflow.
- The input on the ECI pin (P1.2).

Figure 46. PCA Timer/Counter



The CMOD register includes three additional bits associated with the PCA.

- The CIDL bit which allows the PCA to stop during idle mode.
- The ECF bit which when set causes an interrupt and the PCA overflow flag CF in CCON register to be set when the PCA timer overflows.

The CCON register contains the run control bit for the PCA and the flags for the PCA timer and each module.

- The CR bit must be set to run the PCA. The PCA is shut off by clearing this bit.
- The CF bit is set when the PCA counter overflows and an interrupt will be generated if the ECF bit in CMOD register is set. The CF bit can only be cleared by software.
- The CCF0:1 bits are the flags for the modules (CCF0 for module0...) and are set by hardware when either a match or a capture occurs. These flags also can be cleared by software.

PCA Modules

Each one of the two compare/capture modules has six possible functions. It can perform:

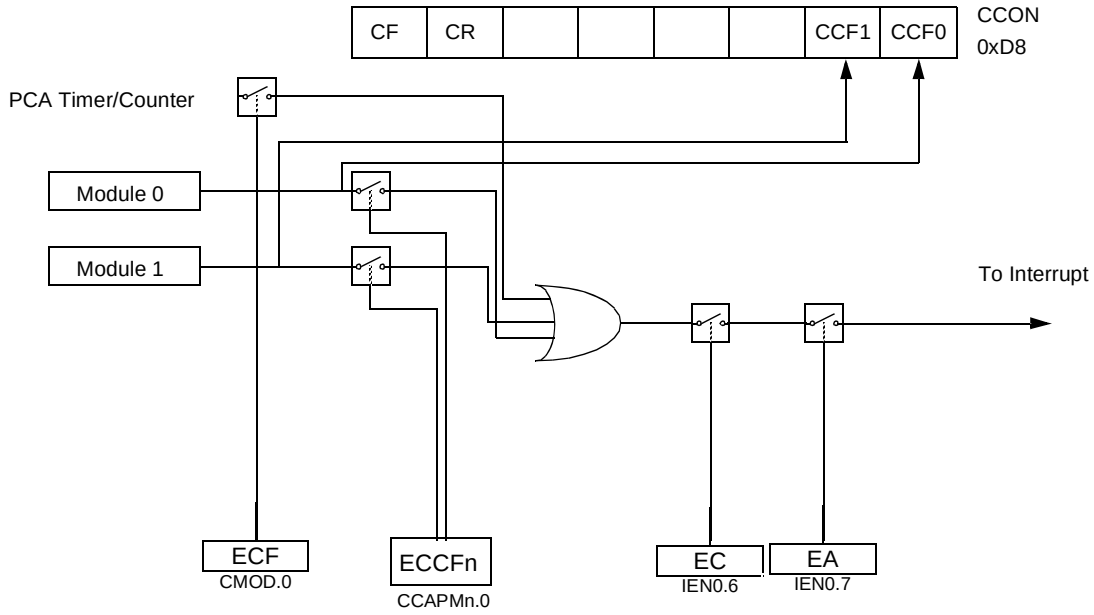
- 16-bit Capture, positive-edge triggered
- 16-bit Capture, negative-edge triggered
- 16-bit Capture, both positive and negative-edge triggered
- 16-bit Software Timer
- 16-bit High Speed Output
- 8-bit Pulse Width Modulator.

Each module in the PCA has a special function register associated with it (CCAPM0 for module 0 ...). The CCAPM0:1 registers contain the bits that control the mode that each module will operate in.

- The ECCF bit enables the CCF flag in the CCON register to generate an interrupt when a match or compare occurs in the associated module.
- The PWM bit enables the pulse width modulation mode.
- The TOG bit when set causes the CEX output associated with the module to toggle when there is a match between the PCA counter and the module's capture/compare register.
- The match bit MAT when set will cause the CCFn bit in the CCON register to be set when there is a match between the PCA counter and the module's capture/compare register.
- The two bits CAPN and CAPP in CCAPMn register determine the edge that a capture input will be active on. The CAPN bit enables the negative edge, and the CAPP bit enables the positive edge. If both bits are set both edges will be enabled.
- The bit ECOM in CCAPM register when set enables the comparator function.

PCA Interrupt

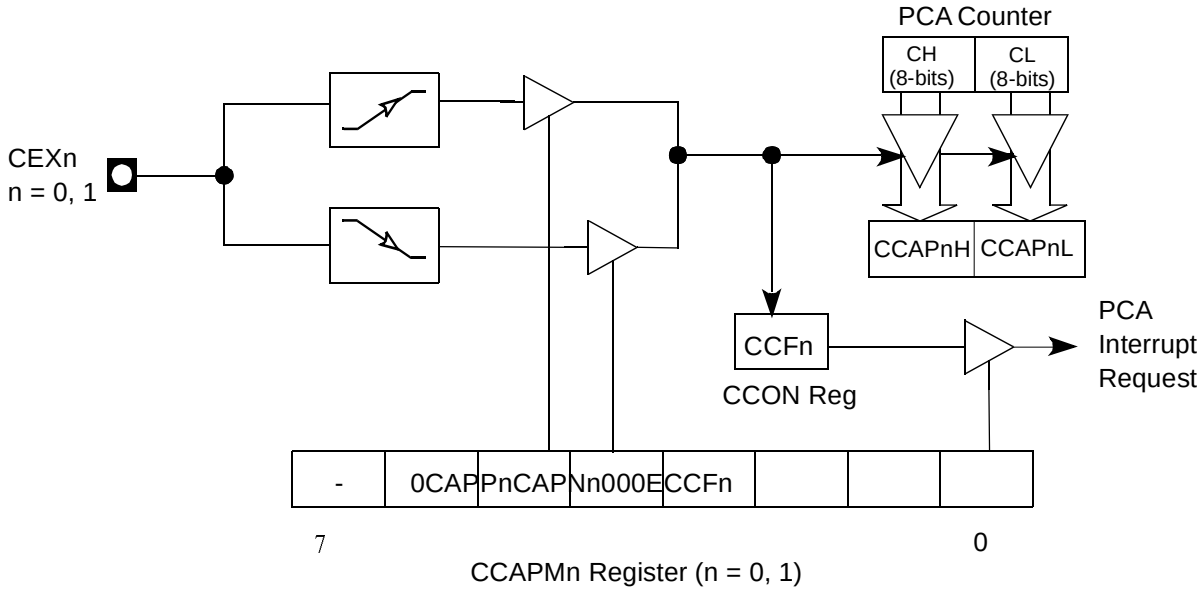
Figure 47. PCA Interrupt System



PCA Capture Mode

To use one of the PCA modules in capture mode either one or both of the CCAPM bits CAPN and CAPP for that module must be set. The external CEX input for the module (on port 1) is sampled for a transition. When a valid transition occurs the PCA hardware loads the value of the PCA counter registers (CH and CL) into the module's capture registers (CCAPnL and CCAPnH). If the CCFn bit for the module in the CCON SFR and the ECCFn bit in the CCAPMn SFR are set then an interrupt will be generated.

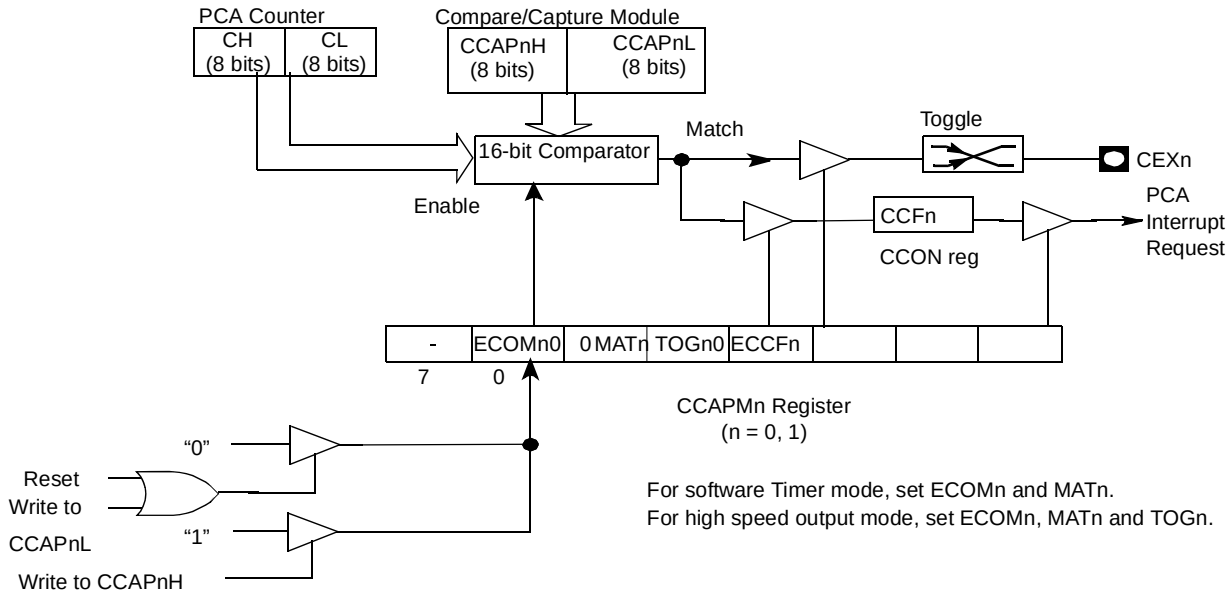
Figure 48. PCA Capture Mode



16-bit Software Timer Mode

The PCA modules can be used as software timers by setting both the ECOM and MAT bits in the modules CCAPMn register. The PCA timer will be compared to the module's capture registers and when a match occurs an interrupt will occur if the CCFn (CCON SFR) and the ECCFn (CCAPMn SFR) bits for the module are both set.

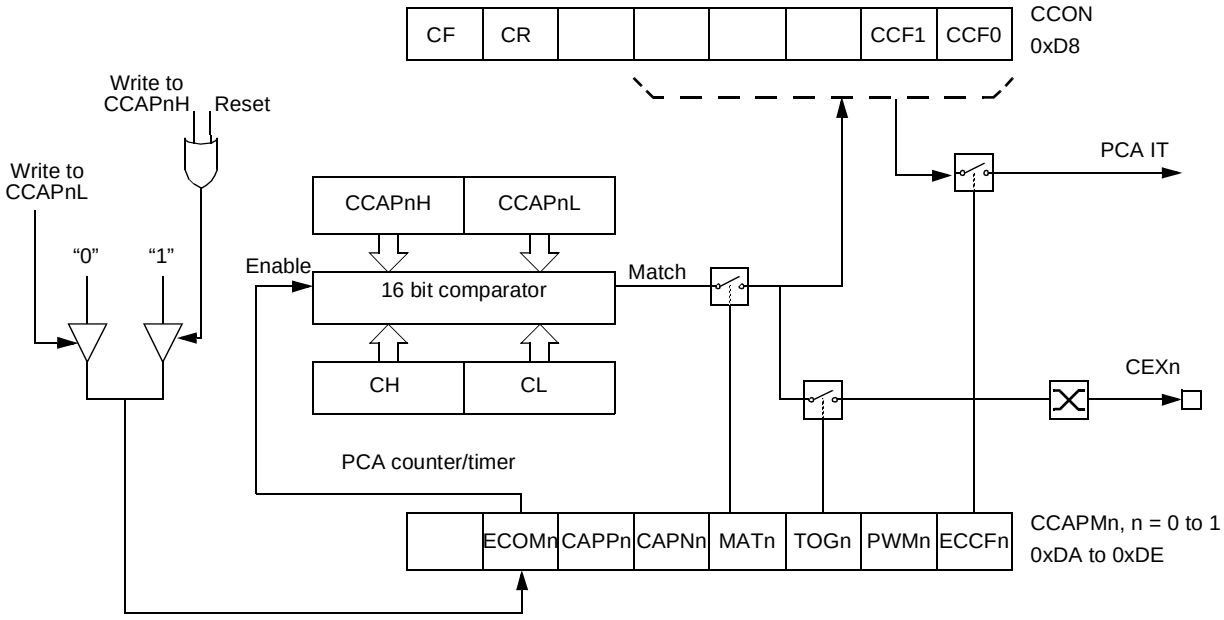
Figure 49. PCA 16-bit Software Timer and High Speed Output Mode



High Speed Output Mode

In this mode the CEX output (on port 1) associated with the PCA module will toggle each time a match occurs between the PCA counter and the module's capture registers. To activate this mode the TOG, MAT, and ECOM bits in the module's CCAPMn SFR must be set.

Figure 50. PCA High Speed Output Mode



Pulse Width Modulator Mode

All the PCA modules can be used as PWM outputs. The output frequency depends on the source for the PCA timer. All the modules will have the same output frequency because they all share the PCA timer. The duty cycle of each module is independently variable using the module's capture register CCAPLn. When the value of the PCA CL SFR is less than the value in the module's CCAPLn SFR the output will be low, when it is equal to or greater than it, the output will be high. When CL overflows from FF to 00, CCAPLn is reloaded with the value in CCAPHn. the allows the PWM to be updated without glitches. The PWM and ECOM bits in the module's CCAPMn register must be set to enable the PWM mode.

Analog-to-Digital Converter (ADC)

This section describes the on-chip 10-bit analog-to-digital converter of the T89C51CC02. Eight ADC channels are available for sampling of the external sources AN0 to AN7. An analog multiplexer allows the single ADC converter to select one from the 8 ADC channels as ADC input voltage (ADCIN). ADCIN is converted by the 10-bit-cascaded potentiometric ADC.

Two modes of conversion are available:
- Standard conversion (8 bits).
- Precision conversion (10 bits).

For the precision conversion, set bit PSIDLE in ADCON register and start conversion. The device is in a pseudo-idle mode, the CPU does not run but the peripherals are always running. This mode allows digital noise to be as low as possible, to ensure high precision conversion.

For this mode it is necessary to work with end of conversion interrupt, which is the only way to wake the device up.

If another interrupt occurs during the precision conversion, it will be served only after this conversion is completed.

Features

- 8 channels with multiplexed inputs
- 10-bit cascaded potentiometric ADC
- Conversion time 16 micro-seconds (typ.)
- Zero Error (offset) ± 2 LSB max
- Positive External Reference Voltage Range (VAREF) 2.4 to 3.0-volt (typ.)
- ADCIN Range 0 to 3-volt
- Integral non-linearity typical 1 LSB, max. 2 LSB
- Differential non-linearity typical 0.5 LSB, max. 1 LSB
- Conversion Complete Flag or Conversion Complete Interrupt
- Selectable ADC Clock

ADC Port1 I/O Functions

Port 1 pins are general I/O that are shared with the ADC channels. The channel select bit in ADCF register define which ADC channel/port1 pin will be used as ADCIN. The remaining ADC channels/port1 pins can be used as general purpose I/O or as the alternate function that is available.

A conversion launched on a channel which are not selected on ADCF register will not have any effect.

VAREF

VAREF should be connected to a low impedance point and must remain in the range specified VAREF absolute maximum range (See section “AC-DC”).

. If the ADC is not used, it is recommended to tie VAREF to VAGND.

Figure 52. ADC Description

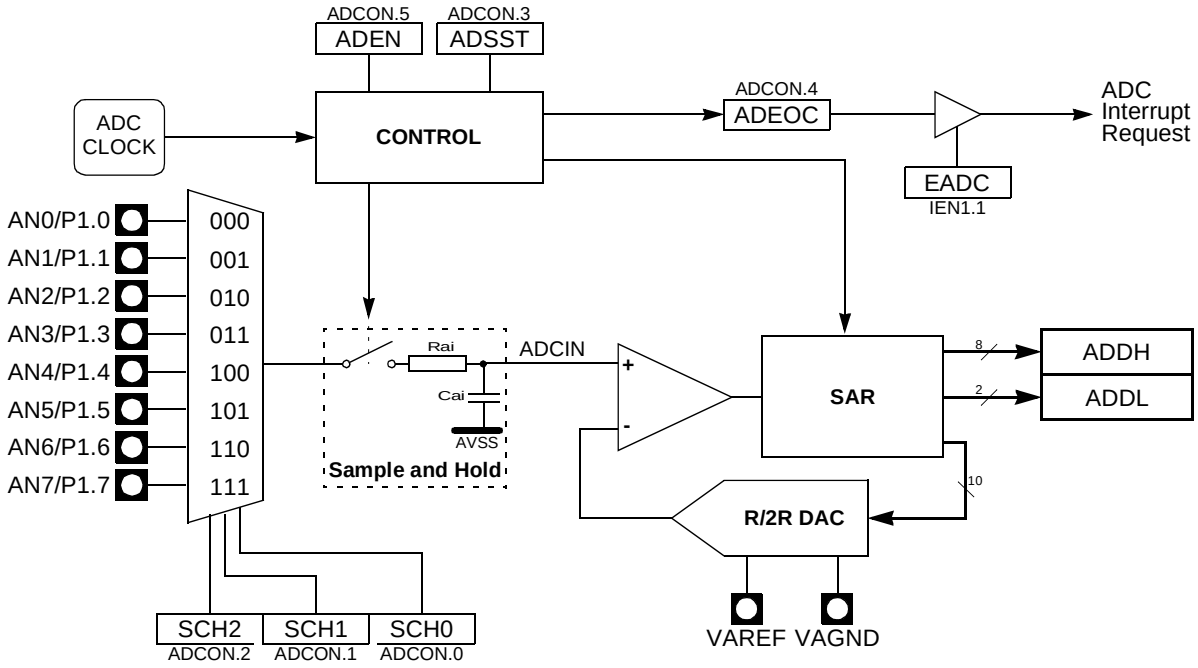

Figure 53 shows the timing diagram of a complete conversion. For simplicity, the figure depicts the waveforms in idealized form and do not provide precise timing information. For ADC characteristics and timing parameters refer to the section “AC Characteristics” of this datasheet.

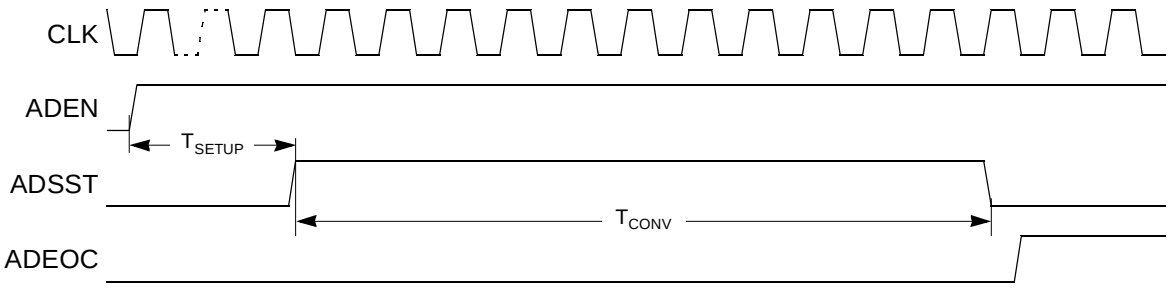
Figure 53. Timing Diagram



Note: Tsetup min, see the AC Parameter for A/D conversion.
Tconv = 11 clock ADC = 1sample and hold + 10-bit conversion
The user must ensure that Tsetup time between setting ADEN and the start of the first conversion.

ADC Converter Operation

A start of single A/D conversion is triggered by setting bit ADSST (ADCON.3).

After completion of the A/D conversion, the ADSST bit is cleared by hardware.

The end-of-conversion flag ADEOC (ADCON.4) is set when the value of conversion is available in ADDH and ADDL, it must be cleared by software. If the bit EADC (IEN1.1) is set, an interrupt occur when flag ADEOC is set (See Figure 55). Clear this flag for re-arming the interrupt.

Note: Always leave Tsetup time before starting a conversion unless ADEN is permanently high. In this case one should wait Tsetup only before the first conversion

The bits SCH0 to SCH2 in ADCON register are used for the analog input channel selection.

Table 102. Selected Analog input

SCH2	SCH1	SCH0	Selected Analog Input
0	0	0	AN0
0	0	1	AN1
0	1	0	AN2
0	1	1	AN3
1	0	0	AN4
1	0	1	AN5
1	1	0	AN6
1	1	1	AN7

Voltage Conversion

When the ADCIN is equals to VAREF the ADC converts the signal to 3FFh (full scale). If the input voltage equals VAGND, the ADC converts it to 000h. Input voltage between VAREF and VAGND are a straight-line linear conversion. All other voltages will result in 3FFh if greater than VAREF and 000h if less than VAGND.

Note that ADCIN should not exceed VAREF absolute maximum range (See section “AC-DC”).

Clock Selection

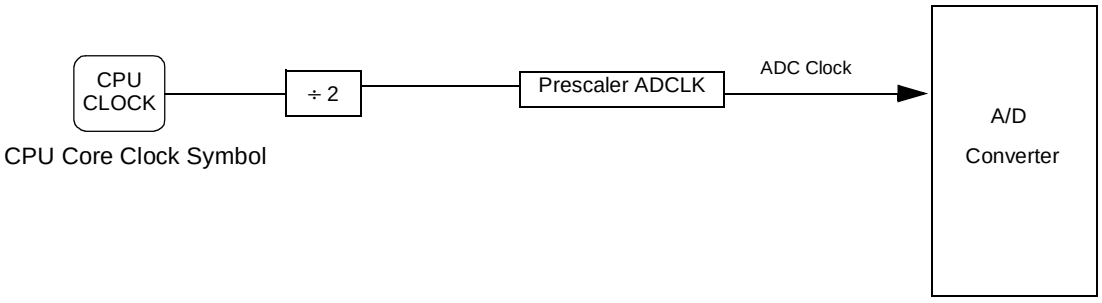
The ADC clock is the same as CPU.

The maximum clock frequency is defined in the DC parmeter for A/D converter. A prescaler is featured (ADCCLK) to generate the ADC clock from the oscillator frequency.

if PRS = 0 then $F_{ADC} = F_{periph} / 64$

if PRS > 0 then $F_{ADC} = F_{periph} / 2 \times PRS$

Figure 54. A/D Converter Clock



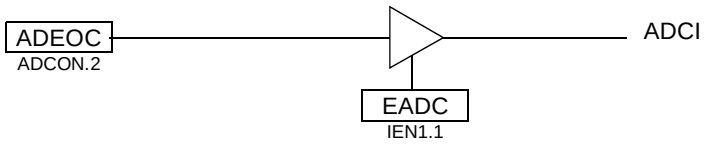
ADC Standby Mode

When the ADC is not used, it is possible to set it in standby mode by clearing bit ADEN in ADCON register. In this mode the power dissipation is reduced.

IT ADC Management

An interrupt end-of-conversion will occurs when the bit ADEOC is activated and the bit EADC is set. For re-arming the interrupt the bit ADEOC must be cleared by software.

Figure 55. ADC interrupt structure



Routine Examples

```
1. Configure P1.2 and P1.3 in ADC channels
// configure channel P1.2 and P1.3 for ADC
 ADCF = 0Ch

// Enable the ADC
 ADCON = 20h
2. Start a standard conversion
// The variable 'channel' contains the channel to convert
// The variable 'value_converted' is an unsigned int
// Clear the field SCH[2:0]
 ADCON &= F8h
// Select channel
 ADCON |= channel
// Start conversion in standard mode
 ADCON |= 08h
// Wait flag End of conversion
 while((ADCON & 01h)!= 01h)
// Clear the End of conversion flag
 ADCON &= EFh
// read the value
 value_converted = (ADDH << 2)+(ADDL)

3. Start a precision conversion (need interrupt ADC)
// The variable 'channel' contains the channel to convert
// Enable ADC
 EADC = 1
// clear the field SCH[2:0]
 ADCON &= F8h
// Select the channel
 ADCON |= channel
// Start conversion in precision mode
 ADCON |= 48h
```

Note: To enable the ADC interrupt: EA = 1

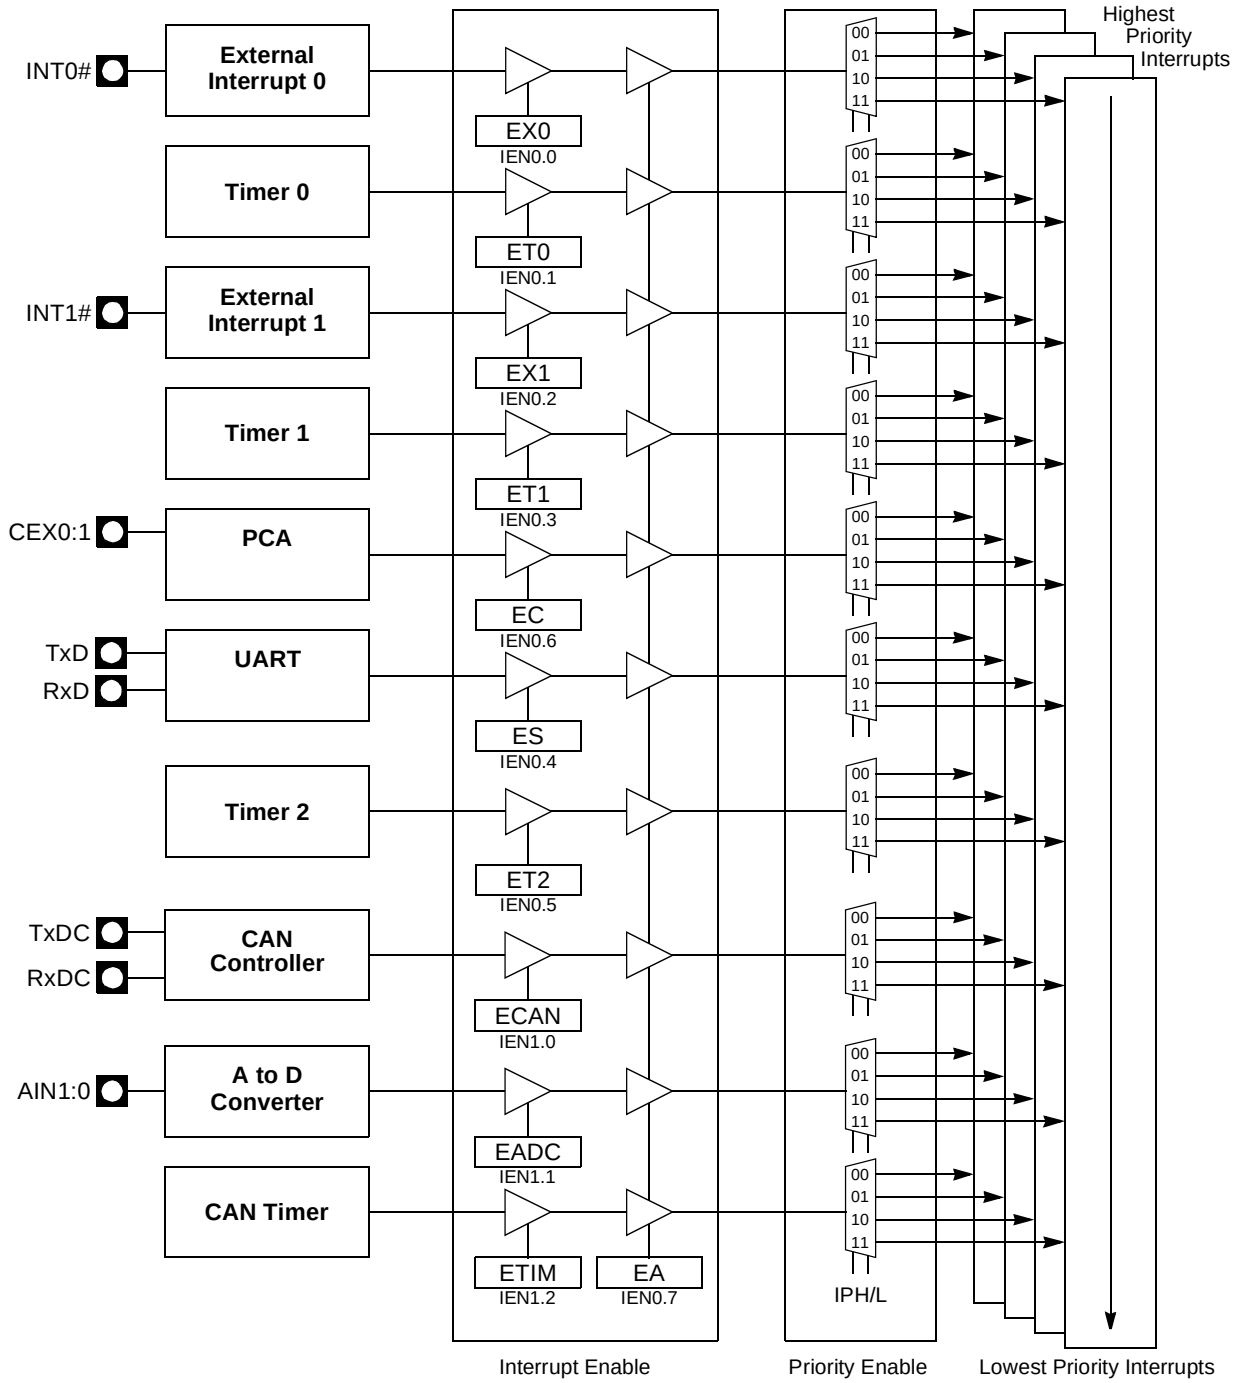
Interrupt System

Introduction

The CAN Controller has a total of 10 interrupt vectors: two external interrupts ($\overline{INT0}$ and $\overline{INT1}$), three timer interrupts (timers 0, 1 and 2), a serial port interrupt, a PCA, a CAN interrupt, a timer overrun interrupt and an ADC. These interrupts are shown below.

Figure 56. Interrupt Control System



Each of the interrupt sources can be individually enabled or disabled by setting or clearing a bit in the Interrupt Enable register. This register also contains a global disable bit which must be cleared to disable all the interrupts at the same time.

Each interrupt source can also be individually programmed to one of four priority levels by setting or clearing a bit in the Interrupt Priority registers. The Table below shows the bit values and priority levels associated with each combination.

Table 108. Priority Level bit Values

IPH.x	IPL.x	Interrupt Level Priority
0	0	0 (Lowest)
0	1	1
1	0	2
1	1	3 (Highest)

A low-priority interrupt can be interrupted by a high priority interrupt but not by another low-priority interrupt. A high-priority interrupt cannot be interrupted by any other interrupt source.

If two interrupt requests of different priority levels are received simultaneously, the request of the higher priority level is serviced. If interrupt requests of the same priority level are received simultaneously, an internal polling sequence determines which request is serviced. Thus within each priority level there is a second priority structure determined by the polling sequence, See Table 109.

Table 109. Interrupt Priority Within Level

Interrupt Name	Interrupt Address Vector	Interrupt Number	Polling Priority
External interrupt (INT0)	0003h	1	1
Timer0 (TF0)	000Bh	2	2
External interrupt (INT1)	0013h	3	3
Timer 1 (TF1)	001Bh	4	4
PCA (CF or CCFn)	0033h	7	5
UART (RI or TI)	0023h	5	6
Timer 2 (TF2)	002Bh	6	7
CAN (Txok, Rxok, Err or OvrBuf)	003Bh	8	8
ADC (ADCI)	0043h	9	9
CAN Timer Overflow (OVRTIM)	004Bh	10	10

Electrical Characteristics

Absolute Maximum Ratings

I = industrial	-40°C to 85°C
Storage Temperature	-65°C to + 150°C
Voltage on V_{CC} from V_{SS}	-0.5V to + 6V
Voltage on Any Pin from V_{SS}	-0.5V to V_{CC} + 0.2V
Power Dissipation	1 W

Note: Stresses at or above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
Power Dissipation value is based on the maximum allowable die temperature and the thermal resistance of the package.

DC Parameters for Standard Voltage

T_A = -40°C to +85°C; V_{SS} = 0 V; V_{CC} = 3 volts to 5.5 volts; F = 0 to 40 MHz

Table 114. DC Parameters in Standard Voltage

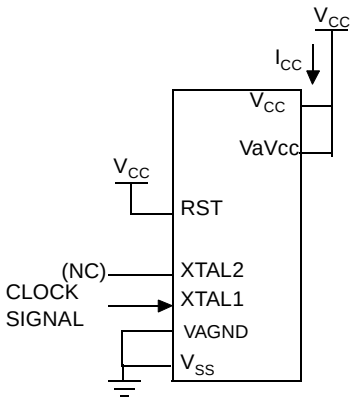
Symbol	Parameter	Min	Typ(1)	Max	Unit	Test Conditions
V_{IL}	Input Low Voltage	-0.5		0.2Vcc - 0.1	V	
V_{IH}	Input High Voltage except XTAL1, RST	0.2 V_{CC} + 0.9		V_{CC} + 0.5	V	
V_{IH1}(2)	Input High Voltage, XTAL1, RST	0.7 V_{CC}		V_{CC} + 0.5	V	
V_{OL}	Output Low Voltage, ports 1, 2, 3 and 4(3)			0.3 0.45 1.0	V V V	I_{OL} = 100 µA I_{OL} = 1.6 mA I_{OL} = 3.5 mA
V_{OH}	Output High Voltage, ports 1, 2, 3, 4 and 5	V_{CC} - 0.3 V_{CC} - 0.7 V_{CC} - 1.5			V V V	I_{OH} = -10 µA I_{OH} = -30 µA I_{OH} = -60 µA V_{CC} = 5V ± 10%
R_{RST}	RST Pulldown Resistor	50	90	200	kΩ	
I_{IL}	Logical 0 Input Current ports 1, 2, 3 and 4			-50	µA	Vin = 0.45V
I_{LI}	Input Leakage Current			±10	µA	0.45V < Vin < V_{CC}
I_{TL}	Logical 1 to 0 Transition Current, ports 1, 2, 3 and 4			-650	µA	Vin = 2.0V
C_{IO}	Capacitance of I/O Buffer			10	pF	Fc = 1 MHz T_A = 25°C
I_{PD}	Power-down Current		160	400	µA	3V < V_{CC} < 5.5V(4)
I_{CC}	Power Supply Current I_{CCOP}(6) = 0.7 Freq (MHz) + 3 mA I_{CCIDLE} (5)= 0.6 Freq (MHz) + 2 mA					

Notes:
1. Typicals are based on a limited number of samples and are not guaranteed. The values listed are at room temperature.
2. Flash retention is guaranteed with the same formula for V_{CC} min down to 0V.
3. Under steady state (non-transient) conditions, I_{OL} must be externally limited as follows:
   Maximum I_{OL} per port pin: 10 mA

Maximum I_{OL} per 8-bit port:
Ports 1, 2 and 3: 15 mA
Maximum total I_{OL} for all output pins: 71 mA
If I_{OL} exceeds the test condition, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.

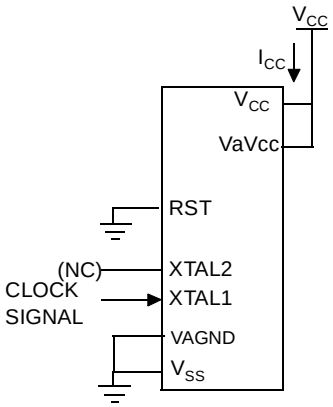
4. Power-down I_{CC} is measured with all output pins disconnected; XTAL2 NC.; RST = V_{SS} (See Figure 61.).
5. Idle I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH}, T_{CHCL} = 5 ns, V_{IL} = V_{SS} + 0.5V, V_{IH} = V_{CC} - 0.5V; XTAL2 N.C; RST = V_{SS} (See Figure 60.).
6. Operating I_{CC} is measured with all output pins disconnected; XTAL1 driven with T_{CLCH}, T_{CHCL} = 5 ns (See Figure 62.), V_{IL} = V_{SS} + 0.5V, V_{IH} = V_{CC} - 0.5V; XTAL2 N.C.; RST = V_{CC}. I_{CC} would be slightly higher if a crystal oscillator used (See Figure 59.).

Figure 59. I_{CC} Test Condition, Active Mode



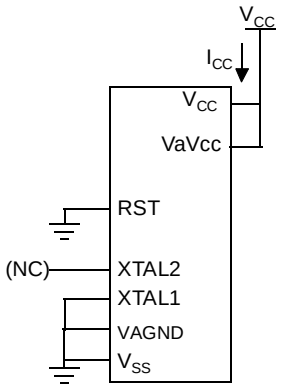
All other pins are disconnected.

Figure 60. I_{CC} Test Condition, Idle Mode



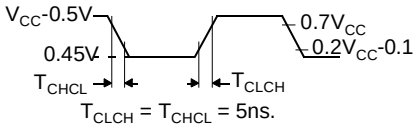
All other pins are disconnected

Figure 61. I_{CC} Test Condition, Power-down Mode



All other pins are disconnected.

Figure 62. Clock Signal Waveform for I_{CC} Tests in Active and Idle Modes



DC Parameters for A/D Converter

Table 115. DC Parameters for AD Converter in Precision Conversion

Symbol	Parameter	Min	Typ(1)	Max	Unit	Test Conditions
AVin	Analog input voltage	Vss- 0.2		Max Vref + 0.6	V	
VaVcc	Analog supply voltage	Vref	Vcc	Vcc + 10%	V	
Rref(2)	Resistance between Varef and Vss	12	16	24	KΩ	
Varef	Reference voltage	2.40		3.00	V	
Cai	Analog input Capacitance		60		pF	During sampling
Rai	Analog input Resistor			400	Ω	During sampling
INL	Integral non linearity		1	2	lsb	
DNL	Differential non linearity		0.5	1	lsb	
OE	Offset error	-2		2	lsb	

Notes: 1. Typicals are based on a limited number of samples and are not guaranteed.
2. With ADC enabled.

AC Parameters

Serial Port Timing - Shift Register Mode

Table 116. Symbol Description (F = 40 MHz)

Symbol	Parameter
T_{XLXL}	Serial port clock cycle time
T_{QVHX}	Output data set-up to clock rising edge
T_{XHQX}	Output data hold after clock rising edge
T_{XHDX}	Input data hold after clock rising edge
T_{XHDV}	Clock rising edge to input data valid

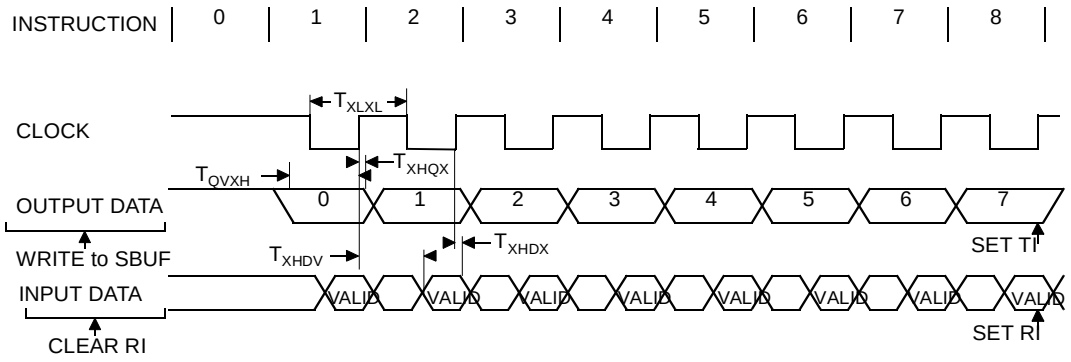
Table 117. AC Parameters for a Fix Clock (F = 40 MHz)

Symbol	Min	Max	Units
T_{XLXL}	300		ns
T_{QVHX}	200		ns
T_{XHQX}	30		ns
T_{XHDX}	0		ns
T_{XHDV}		117	ns

Table 118. AC Parameters for a Variable Clock

Symbol	Type	Standard Clock	X2 Clock	x parameter for -M range	Units
T_{XLXL}	Min	12 T	6 T		ns
T_{QVHX}	Min	10 T - x	5 T - x	50	ns
T_{XHQX}	Min	2 T - x	T - x	20	ns
T_{XHDX}	Min	x	x	0	ns
T_{XHDV}	Max	10 T - x	5 T- x	133	ns

Shift Register Timing Waveforms

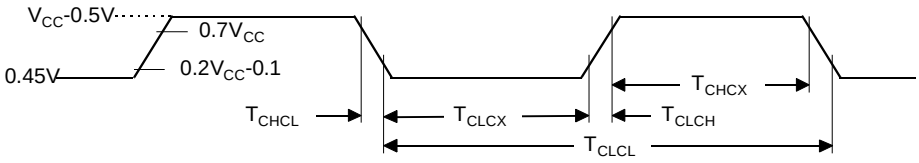


External Clock Drive Characteristics (XTAL1)

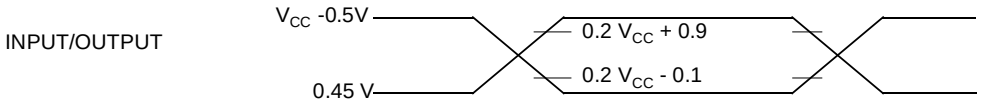
Table 119. AC Parameters

Symbol	Parameter	Min	Max	Units
T_{CLCL}	Oscillator Period	25		ns
T_{CHCX}	High Time	5		ns
T_{CLCX}	Low Time	5		ns
T_{CLCH}	Rise Time		5	ns
T_{CHCL}	Fall Time		5	ns
T_{CHCX}/T_{CLCX}	Cyclic ratio in X2 Mode	40	60	%

External Clock Drive Waveforms

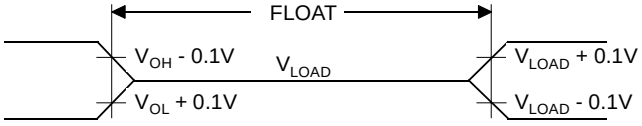


AC Testing Input/Output Waveforms



AC inputs during testing are driven at V_{CC} - 0.5 for a logic “1” and 0.45V for a logic “0”. Timing measurement are made at V_{IH} min for a logic “1” and V_{IL} max for a logic “0”.

Float Waveforms



For timing purposes as port pin is no longer floating when a 100 mV change from load voltage occurs and begins to float when a 100 mV change from the loaded V_{OH}/V_{OL} level occurs. $I_{OL}/I_{OH} \geq \pm 20mA$.

Clock Waveforms

Valid in normal clock mode. In X2 Mode XTAL2 must be changed to XTAL2/2.

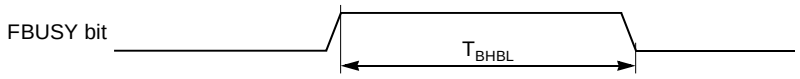
Flash/EEPROM Memory

Table 120. Memory AC Timing

V_{cc} = 3.0V to 5.5V, T_A = -40°C to +85°C

Symbol	Parameter	Min	Typ	Max	Unit
T_{BHBL}	Flash/EEPROM Internal Busy (Programming) Time		13	17	ms
N_{FCY}	Number of Flash/EEPROM Erase/Write Cycles	100 000			cycles
T_{FDR}	Flash/EEPROM Data Retention Time	10			years

Figure 63. Flash Memory - Internal Busy Waveforms



A/D Converter

Table 121. AC Parameters for A/D Conversion

Symbol	Parameter	Min	Typ	Max	Unit
T_{SETUP}		4			µs
ADC Clock Frequency			700		KHz

Factory default programming for T89C51CC02CA-xxxx is Bootloader CAN and HSB = BBh:

- X1 mode
- BLJB = 0 : jump to Bootloader
- LB2 = 0 : Security Level 3.[1]

Factory default programming for T89C51CC02UA-xxxx is Bootloader UART and HSB = BBh:

- X1 mode
- BLJB = 0 : jump to Bootloader
- LB2 = 0 : Security Level 3.[1]

Notes: 1. LB2 = 0 is not described in Table 22 Program load bit. LB2 = 0 is equivalent to LB1 = 0: Security Level 3.
2. Customer can change these modes by re-programming with a parallel programmer, this can be done by an Atmel distributor.

Datasheet Revision History

Changes from 4126C-10/02 to 4126D - 04/03

1. Changed the endurance of Flash to 100, 000 Write/Erase cycles.
2. Added note on Flash retention formula for V_{IH1}, in Section "DC Parameters for Standard Voltage", page 141.Changes from 4129F-11/02 to 4129G-04/03
1. Changed the endurance of Flash to 100, 000 Write/Erase cycles.
2. Added note on Flash retention formula for V_{IH1}, in Section "DC Parameters for Standard Voltage", page 141.

Changes from 4126D - 05/03 to 4126E - 10/03

1. Updated “Electrical Characteristics” on page 140.
2. Corrected Figure 39 on page 82.

Changes from 4126E - 10/03 to 4126F - 12/03

1. Changed value of IPDMAX to 400, Section "Absolute Maximum Ratings", page 140.
2. PCA , CPS0, register correction, Section "PCA Registers", page 121.
3. Cross Memory section added. Section "Operation Cross Memory Access", page 44.

Changes from 4126F - 12/03 4126G - 08/04

1. Figure clock-out mode modified see, Figure 30 on page 65.
2. Corrected error in Table 51 on page 70, (1.25ms to 1.25s) for Time-out Computation.
3. Added explanation on the CAN protocol, see Section “CAN Controller”, page 73.

Changes from 4126G - 08/04 to 4126H - 01/05

1. Various minor corrections throughout the document.

Changes from 4126H - 01/05 to 4126I 11/05

1. Added Green product ordering information.

Changes from 4126I to 4126J 05/06

1. Minor corrections throughout the document.
