

MAX828, MAX829

Switched Capacitor Voltage Converter

The MAX828 and MAX829 are CMOS charge pump voltage inverters that are designed for operation over an input voltage range of 1.15 V to 5.5 V with an output current capability in excess of 50 mA. The operating current consumption is only 68 μA for the MAX828 and 118 μA for the MAX829. The devices contain an internal oscillator that operates at 12 kHz for the MAX828 and 35 kHz for the MAX829. The oscillator drives four low resistance MOSFET switches, yielding a low output resistance of 26 Ω and a voltage conversion efficiency of 99.9%. These devices require only two external capacitors, 10 μF for the MAX828 and 3.3 μF for the MAX829, for a complete inverter making it an ideal solution for numerous battery powered and board level applications. The MAX828 and MAX829 are available in the space saving Thin SOT-23-5 package.

Features

- Pb-Free Packages are Available
- Operating Voltage Range of 1.15 V to 5.5 V
- Output Current Capability in Excess of 50 mA
- Low Current Consumption of 68 μA (MAX828) or 118 μA (MAX829)
- Operation at 12 kHz (MAX828) or 35 kHz (MAX829)
- Low Output Resistance of 26 Ω
- Space Saving Thin SOT-23-5 Package

Typical Applications

- LCD Panel Bias
- Cellular Telephones
- Pagers
- Personal Digital Assistants
- Electronic Games
- Digital Cameras
- Camcorders
- Hand-Held Instruments

This device contains 77 active transistors.

MAXIMUM RATINGS*

Rating	Symbol	Value	Unit
Input Voltage Range (V_{in} to GND)	V_{in}	-0.3 to 6.0	V
Output Voltage Range (V_{out} to GND)	V_{out}	-6.0 to 0.3	V
Output Current (Note 1)	I_{out}	100	mA
Output Short Circuit Duration (V_{out} to GND, Note 1)	t_{SC}	Indefinite	sec
Operating Junction Temperature	T_J	150	°C
Power Dissipation and Thermal Characteristics Thermal Resistance, Junction to Air Maximum Power Dissipation @ $T_A = 70^\circ\text{C}$	$R_{\theta JA}$ P_D	256 313	°C/W mW
Storage Temperature	T_{stg}	-55 to 150	°C

Maximum ratings are those values beyond which device damage can occur. Maximum ratings applied to the device are individual stress limit values (not normal operating conditions) and are not valid simultaneously. If these limits are exceeded, device functional operation is not implied, damage may occur and reliability may be affected.

DETAILED OPERATING DESCRIPTION

The MAX828/829 charge pump converts inverts the voltage applied to the V_{in} pin. Conversion consists of a two-phase operation (Figure 21). During the first phase, switches S₂ and S₄ are open and S₁ and S₃ are closed. During this time, C₁ charges to the voltage on V_{in} and load current is supplied from C₂. During the second phase, S₂ and S₄ are closed, and S₁ and S₃ are open. This action connects C₁ across C₂, restoring charge to C₂.

Figure 21. Ideal Switched Capacitor Charge Pump

APPLICATIONS INFORMATION

Output Voltage Considerations

The MAX828/829 performs voltage conversion but does not provide regulation. The output voltage will drop in a linear manner with respect to load current. The value of this equivalent output resistance is approximately 26 Ω nominal at 25°C and V_{in} = 5.0 V. V_{out} is approximately -5.0 V at light loads, and drops according to the equation below:

$$V_{DROP} = I_{out} \times R_{out}$$

$$V_{out} = - (V_{in} - V_{DROP})$$

Charge Pump Efficiency

The overall power efficiency of the charge pump is affected by four factors:

1. Losses from power consumed by the internal oscillator, switch drive, etc. (which vary with input voltage, temperature and oscillator frequency).
2. I²R losses due to the on-resistance of the MOSFET switches on-board the charge pump.
3. Charge pump capacitor losses due to Equivalent Series Resistance (ESR).
4. Losses that occur during charge transfer from the commutation capacitor to the output capacitor when a voltage difference between the two capacitors exists.

Most of the conversion losses are due to factors 2, 3 and 4. These losses are given by Equation 1.

$$P_{LOSS(2,3,4)} = I_{out}^2 \times R_{out} \cong I_{out}^2 \times \left[\frac{1}{(f_{OSC})C_1} + 8R_{SWITCH} + 4ESR_{C_1} + ESR_{C_2} \right]$$

(eq. 1)

The 1/(f_{osc})(C₁) term in Equation 1 is the effective output resistance of an ideal switched capacitor circuit (Figures 22 and 23).

The losses due to charge transfer above are also shown in Equation 2. The output voltage ripple is given by Equation 3.

$$P_{LOSS} = [0.5C_1 (V_{in}^2 - V_{out}^2) + 0.5C_2 (V_{RIPPLE}^2 - 2V_{out}V_{RIPPLE})] \times f_{OSC}$$

(eq. 2)

$$V_{RIPPLE} = \frac{I_{out}}{(f_{OSC})(C_2)} + 2(I_{out})(ESR_{C_2})$$

(eq. 3)

Figure 23. Equivalent Output Resistance

MAX828, MAX829

Capacitor Selection

In order to maintain the lowest output resistance and output ripple voltage, it is recommended that low ESR capacitors be used. Additionally, larger values of C_1 will lower the output resistance and larger values of C_2 will reduce output voltage ripple. (See Equation 3).

Table 1 shows various values of C_1 , C_2 and C_3 with the corresponding output resistance values at 25°C. Table 2 shows the output voltage ripple for various values of C_1 , C_2 and C_3 . The data in Tables 1 and 2 was measured not calculated.

Table 1. Output Resistance vs. Capacitance
($C_1 = C_2 = C_3$), $V_{in} = 4.75\text{ V}$ and $V_{out} = -4.0\text{ V}$

$C_1 = C_2 = C_3$ (μF)	MAX828 R_{out} (Ω)	MAX829 R_{out} (Ω)

10	126	51.25
24	55.1	25.2
50	36.6	27.85

Input Supply Bypassing

The input voltage, V_{in} should be capacitively bypassed to reduce AC impedance and minimize noise effects due to the switching internals in the device. If the device is loaded from V_{out} to GND, it is recommended that a large value capacitor (at least equal to C_1) be connected from V_{in} to GND. If the device is loaded from V_{in} to V_{out} a small ($0.7\ \mu\text{F}$) capacitor between the pins is sufficient.

Voltage Inverter

The most common application for a charge pump is the voltage inverter (Figure 20). This application uses two or three external capacitors. The capacitors C_1 (pump capacitor) and C_2 (output capacitor) are required. The input bypass capacitor C_3 , may be necessary depending on the application. The output is equal to $-V_{in}$ plus any voltage drops due to loading. Refer to Tables 1 and 2 for capacitor selection. The test setup used for the majority of the characterization is shown in Figure 20.

Layout Considerations

As with any switching power supply circuit, good layout practice is recommended. Mount components as close together as possible to minimize stray inductance and capacitance. Also use a large ground plane to minimize noise leakage into other circuitry.

Capacitor Resources

Selecting the proper type of capacitor can reduce switching loss. Low ESR capacitors are recommended. The MAX828 and MAX829 were characterized using the capacitors listed in Table 3. This list identifies low ESR capacitors for the voltage inverter application.

Figure 24. Voltage Inverter

MAX828, MAX829

The MAX828 / 829 primary function is a voltage inverter. The device will convert 5.0 V into -5.0 V with light loads. Two capacitors are required for the inverter to function. A third capacitor, the input bypass capacitor, may be required depending on the power source for the inverter. The performance for this device is illustrated below.

Figure 26. Voltage Inverter Load Regulation Output Voltage vs. Output Current MAX829

Figure 27. Cascade Devices for Increased Negative Output Voltage

Two or more devices can be cascaded for increased output voltage. Under light load conditions, the output voltage is approximately equal to $-V_{in}$ times the number of stages. The converter output resistance increases dramatically with each additional stage. This is due to a reduction of input voltage to each successive stage as the converter output is loaded. Note that the ground connection for each successive stage must connect to the negative output of the previous stage. The performance characteristics for a converter consisting of two cascaded devices are shown below.

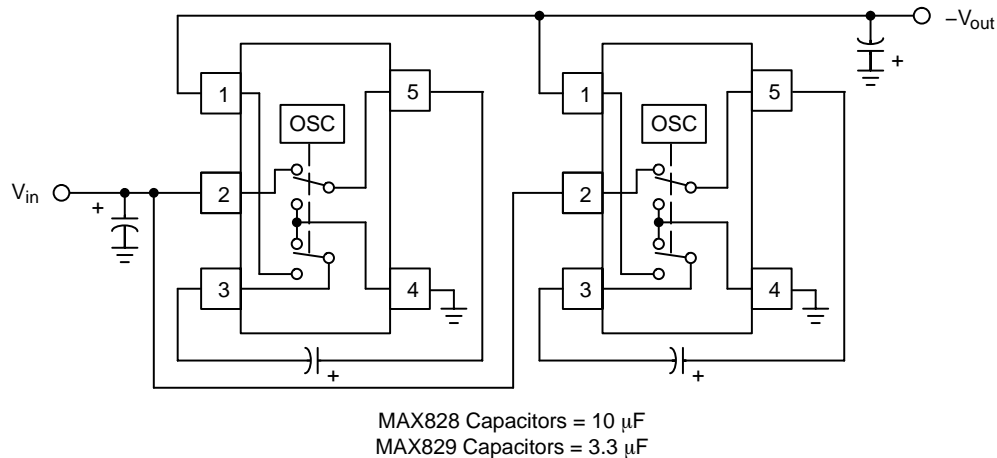

Figure 42. Paralleling Devices for Increased Negative Output Current

An increase in converter output current capability with a reduction in output resistance can be obtained by paralleling two or more devices. The output current capability is approximately equal to the number of devices paralleled. A single shared output capacitor is sufficient for proper operation but each device does require its own pump capacitor. Note that the output ripple frequency will be complex since the oscillators are not synchronized. The output resistance is approximately equal to the output resistance of one device divided by the total number of devices paralleled. The performance characteristics for a converter consisting of two paralleled devices is shown below.

MAX828, MAX829

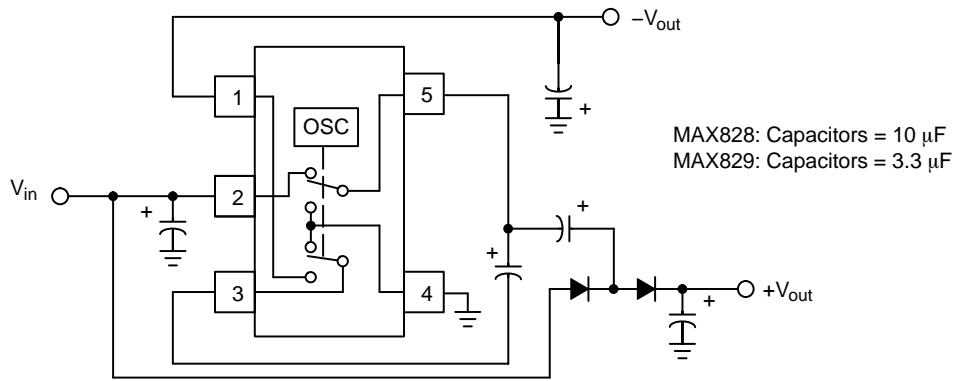

Figure 51. A Positive Doubler, with a Negative Inverter

All of the previously shown converter circuits have only single outputs. Applications requiring multiple outputs can be constructed by incorporating combinations of the former circuits. The converter shown above combines Figures 24 and 36 to form a negative output inverter with a positive output doubler. Different combinations of load regulation are shown below. In Figures 52 and 53 the positive doubler has a constant $I_{out} = 15 \text{ mA}$ while the negative inverter has the variable load. In Figures 54 and 55 the negative inverter has the constant $I_{out} = 15 \text{ mA}$ and the positive doubler has the variable load.
