4-bit up/down binary synchronous counter 74F169

FEATURES

- Synchronous counting and loading
- Up/Down counting
- Modulo 16 binary counter
- Two Count Enable inputs for n-bit cascading
- Positive edge-triggered clock
- Built-in carry look-ahead capability
- Presettable for programmable operation

DESCRIPTION

The 74F169 is a 4-bit synchronous, presettable Modulo 16 up/down counter featuring an internal carry look-ahead for applications in high-speed counting designs. Synchronous operation is provided by having all flip-flops clocked simultaneously so that the outputs change coincident with each other when instructed by the Count Enable inputs and internal gating. This mode of operation eliminates the output spikes which are normally associated with asynchronous (ripple clock) counters. A buffered clock input triggers the flip-flops on the Low-to-High transition of the clock.

The counter is fully programmable; that is, the outputs may be preset to either level.

Presetting is synchronous with the clock and takes place regardless of the levels of the Count Enable inputs. A Low level on the Parallel Enable ($\overline{PE}$) input disables the counter and causes the data at the D_n input to be loaded into the counter on the next Low-to-High transition of the clock.

The direction of counting is controlled by the Up/Down (U/$\overline{D}$) input; a High will cause the count to increase, a Low will cause the count to decrease.

The carry look-ahead circuitry provides for n-bit synchronous applications without additional gating. Instrumental in accomplishing this function are two Count Enable inputs ($\overline{CET}$, $\overline{CEP}$) and a Terminal Count ($\overline{TC}$) output. Both Count Enable inputs must be Low to count. The $\overline{CET}$ input is fed forward to enable the $\overline{TC}$ output. The $\overline{TC}$ output thus enabled will produce a Low output pulse with a duration approximately equal to the High level portion of the Q_0 output. The Low level $\overline{TC}$ pulse is used to enable successive cascaded stages.

FUNCTIONAL DESCRIPTION

The 74F169 uses edge-triggered J-K-type flip-flops and have no constraints on changing the control or data input signals in either state of the clock. The only requirement is that the various inputs attain the desired state at least a setup time before the rising edge of the clock and remain valid for the recommended hold time thereafter. The parallel load operation takes precedence over the other operations, as indicated in the Mode Select Table. When $\overline{PE}$ is Low, the data on the D_0 - D_3 inputs enter the flip-flops on the next rising edge of the Clock. In order for counting to occur, both $\overline{CEP}$ and $\overline{CET}$ must be Low and $\overline{PE}$ must be High; the U/$\overline{D}$ input determines the direction of counting. The Terminal Count ($\overline{TC}$) output is normally High and goes Low, provided that $\overline{CET}$ is Low, when a counter reaches zero in the Count Down mode or reaches 15 in the Count Up mode. The $\overline{TC}$ output state is not a function of the Count Enable Parallel ($\overline{CEP}$) input level. Since the $\overline{TC}$ signal is derived by decoding the flip-flop states, there exists the possibility of decoding spikes on $\overline{TC}$. For this reason the use of $\overline{TC}$ as a clock signal is not recommended (see logic equations below).

1) Count Enable = $\overline{CEP}\cdot\overline{CET}\cdot\overline{PE}$

2) Up: $\overline{TC} = Q_0\cdot Q_3\cdot(U/\overline{D})\cdot\overline{CET}$

3) Down: $\overline{TC} = Q_0\cdot Q_1\cdot Q_2\cdot Q_3\cdot(U/\overline{D})\cdot\overline{CET}$

I_{CC}	Supply current (total)[4]		V_{CC} = MAX			35	52	mA

NOTES:

1. For conditions shown as MIN or MAX, use the appropriate value specified under recommended operating conditions for the applicable type.
2. All typical values are at V_{CC} = 5V, T_{amb} = 25°C.
3. Not more than one output should be shorted at a time. For testing I_{OS}, the use of high-speed test apparatus and/or sample-and-hold techniques are preferable in order to minimize internal heating and more accurately reflect operational values. Otherwise, prolonged shorting of a High output may raise the chip temperature well above normal and thereby cause invalid readings in other parameter tests. In any sequence of parameter tests, I_{OS} tests should be performed last.
4. I_{CC} is measured after applying a momentary 4.5V, then ground to the clock input with all other inputs grounded and all outputs open.
