## LH28F320S5-L90/12 32-MBIT (4MBx8/2MBx16) Smart 5 Flash MEMORY

- Smart 5 Technology
   5V V<sub>CC</sub>
   5V V<sub>PP</sub>
- Common Flash Interface (CFI)
   Universal & Upgradable Interface
- Scalable Command Set (SCS)
- High Speed Write Performance
   32 Bytes x 2 plane Page Buffer
   2µS/Byte Write Transfer Rate
- High Speed Read Performance — 90/12: 90ns(5V±5%), 100/120ns(5V±10%)
- Enhanced Automated Suspend Options
  - Write Suspend to Read
  - Block Erase Suspend to Write
  - Block Erase Suspend to Read
- Industry-Standard Packaging — 56-Lead SSOP
- Chip Size Packaging — 64-Lead CSP
- SRAM-Compatible Write Interface
- User-Configurable x8 or x16 Operation

- High-Density Symmetrically-Blocked Architecture
  - Sixty-four 64-Kbyte Erasable Blocks
- Enhanced Data Protection Features
   Absolute Protection with V<sub>PP</sub>=GND
  - Flexible Block Locking
  - --- Erase/Write Lockout during Power Transitions
- Extended Cycling Capability
  - 100,000 Block Erase Cycles
  - 6.4 Million Block Erase Cycles/Chip
- Low Power Management
  - Deep Power-Down Mode
  - Automatic Power Savings Mode
     Decreases I<sub>CC</sub> in Static Mode
- Automated Write and Erase
   Command User Interface
   Status Register
- ETOX<sup>TM\*</sup> V Nonvolatile Flash Technology
- Not designed or rated as radiation hardened

SHARP's LH28F320S5-L90/12 Flash memory with Smart 5 technology is a high-density, low-cost, nonvolatile, read/write storage solution for a wide range of applications. Its symmetrically-blocked architecture, flexible voltage and extended cycling provide for highly flexible component suitable for resident flash arrays, SIMMs and memory cards. Its enhanced suspend capabilities provide for an ideal solution for code + data storage applications. For secure code storage applications, such as networking, where code is either directly executed out of flash or downloaded to DRAM, the LH28F320S5-L90/12 offers three levels of protection: absolute protection with V<sub>PP</sub> at GND, selective hardware block locking, or flexible software block locking. These alternatives give designers ultimate control of their code security needs.

The LH28F320S5-L90/12 is conformed to the flash Scalable Command Set (SCS) and the Common Flash Interface (CFI) specification which enable universal and upgradable interface, enable the highest system/device data transfer rates and minimize device and system-level implementation costs.

The LH28F320S5-L90/12 is manufactured on SHARP's 0.4µm ETOX<sup>TM\*</sup> V process technology. It comes in industry-standard package: the 56-Lead SSOP or Chip size package: the 64-Lead CSP, ideal for board constrained applications.

\*ETOX is a trademark of Intel Corporation.

- •Handle this document carefully for it contains material protected by international copyright law. Any reproduction, full or in part, of this material is prohibited without the express written permission of the company.
- •When using the products covered herein, please observe the conditions written herein and the precautions outlined in the following paragraphs. In no event shall the company be liable for any damages resulting from failure to strictly adhere to these conditions and precautions.
  - (1) The products covered herein are designed and manufactured for the following application areas. When using the products covered herein for the equipment listed in Paragraph (2), even for the following application areas, be sure to observe the precautions given in Paragraph (2). Never use the products for the equipment listed in Paragraph (3).
    - •Office electronics
    - •Instrumentation and measuring equipment
    - •Machine tools
    - •Audiovisual equipment
    - •Home appliance
    - •Communication equipment other than for trunk lines
  - (2) Those contemplating using the products covered herein for the following equipment which demands high reliability, should first contact a sales representative of the company and then accept responsibility for incorporating into the design fail-safe operation, redundancy, and other appropriate measures for ensuring reliability and safety of the equipment and the overall system.
    - •Control and safety devices for airplanes, trains, automobiles, and other transportation equipment
    - •Mainframe computers
    - •Traffic control systems
    - •Gas leak detectors and automatic cutoff devices
    - •Rescue and security equipment
    - •Other safety devices and safety equipment, etc.
- (3) Do not use the products covered herein for the following equipment which demands extremely high performance in terms of functionality, reliability, or accuracy.
  - Aerospace equipment
  - •Communications equipment for trunk lines
  - •Control equipment for the nuclear power industry
  - •Medical equipment related to life support, etc.
- (4) Please direct all queries and comments regarding the interpretation of the above three Paragraphs to a sales representative of the company.
- Please direct all queries regarding the products covered herein to a sales representative of the company.

#### LH28F320S5-L90/12 Smart 5 Flash MEMORY

#### **1** INTRODUCTION

This datasheet contains LH28F320S5-L90/12 specifications. Section 1 provides a flash memory overview. Sections 2, 3, 4, and 5 describe the memory organization and functionality. Section 6 covers electrical specifications.

#### **1.1 Product Overview**

The LH28F320S5-L90/12 is a high-performance 32-Mbit Smart 5 Flash memory organized as 4MBx8/2MBx16. The 4MB of data is arranged in sixty-four 64-Kbyte blocks which are individually erasable, lockable, and unlockable in-system. The memory map is shown in Figure 4.

Smart 5 technology provides a choice of V<sub>CC</sub> and V<sub>PP</sub> combinations, as shown in Table 1, to meet system performance and power expectations. 5V V<sub>CC</sub> provides the highest read performance. V<sub>PP</sub> at 5V eliminates the need for a separate 12V converter, while V<sub>PP</sub>=5V maximizes erase and write performance. In addition to flexible erase and program voltages, the dedicated V<sub>PP</sub> pin gives complete data protection when V<sub>PP</sub>  $\leq$  V<sub>PPLK</sub>.

 Table 1. V<sub>CC</sub> and V<sub>PP</sub> Voltage Combinations

 Offered by Smart 5 Technology

| V <sub>CC</sub> Voltage | V <sub>PP</sub> Voltage |
|-------------------------|-------------------------|
| 5V                      | 5V                      |

Internal  $V_{CC}$  and  $V_{PP}$  detection Circuitry automatically configures the device for optimized read and write operations.

A Command User Interface (CUI) serves as the interface between the system processor and internal operation of the device. A valid command sequence written to the CUI initiates device automation. An internal Write State Machine (WSM) automatically executes the algorithms and timings necessary for block erase, full chip erase, (multi) word/byte write and block lock-bit configuration operations.

A block erase operation erases one of the device's 64-Kbyte blocks typically within 0.34 second (5V  $V_{CC}$ ,

 $5V V_{pp}$ ) independent of other blocks. Each block can be independently erased 100,000 times (6.4 million block erases per device). Block erase suspend mode allows system software to suspend block erase to read or write data from any other block.

A word/byte write is performed in byte increments typically within 9.24  $\mu$ s (5V V<sub>CC</sub>, 5V V<sub>PP</sub>). A multi word/byte write has high speed write performance of 2  $\mu$ s/byte (5V V<sub>CC</sub>, 5V V<sub>PP</sub>). (Multi) Word/byte write suspend mode enables the system to read data or execute code from any other flash memory array location.

Individual block locking uses a combination of bits and WP#, Sixty-four block lock-bits, to lock and unlock blocks. Block lock-bits gate block erase, full chip erase and (multi) word/byte write operations. Block lock-bit configuration operations (Set Block Lock-Bit and Clear Block Lock-Bits commands) set and cleared block lock-bits.

The status register indicates when the WSM's block erase, full chip erase, (multi) word/byte write or block lock-bit configuration operation is finished.

The STS output gives an additional indicator of WSM activity by providing both a hardware signal of status (versus software polling) and status masking (interrupt masking for background block erase, for example). Status polling using STS minimizes both CPU overhead and system power consumption. STS pin can be configured to different states using the Configuration command. The STS pin defaults to RY/BY# operation. When low, STS indicates that the WSM is performing a block erase, full chip erase, (multi) word/byte write or block lock-bit configuration. STS-High Z indicates that the WSM is ready for a new command, block erase is suspended and (multi) word/byte write are inactive, (multi) word/byte write are suspended, or the device is in deep power-down mode. The other 3 alternate configurations are all pulse mode for use as a system interrupt.

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

The access time is 90ns ( $t_{AVAV}$ ) over the commercial temperature range (0°C to +70°C) and V<sub>CC</sub> supply voltage range of 4.75V-5.25V. At lower V<sub>CC</sub> voltages, the access times are 100ns/120ns (4.5V-5.5V).

The Automatic Power Savings (APS) feature substantially reduces active current when the device is in static mode (addresses not switching). In APS mode, the typical  $I_{CCR}$  current is 1 mA at 5V  $V_{CC}$ .

When either  $CE_0$  or  $CE_1$ , and RP# pins are at  $V_{CC}$ , the  $I_{CC}$  CMOS standby mode is enabled. When the RP# pin is at GND, deep power-down mode is

enabled which minimizes power consumption and provides write protection during reset. A reset time  $(t_{PHQV})$  is required from RP# switching high until outputs are valid. Likewise, the device has a wake time  $(t_{PHEL})$  from RP#-high until writes to the CUI are recognized. With RP# at GND, the WSM is reset and the status register is cleared.

The device is available in 56-Lead SSOP (Shrink Small Outline Package) and 64-Lead CSP (Chip Size Package). Pinout is shown in Figure 2 and 3.

| Table 2. Pin Descriptions               |                         |  |  |  |  |  |  |
|---|-------------------------|--|--|--|--|--|--|
| Symbol                                  | Туре                    | Name and Function  |  |  |  |  |  |
| A <sub>0</sub> -A <sub>21</sub>         | INPUT                   | ADDRESS INPUTS: Inputs for addresses during read and write operations. Addresses are<br>internally latched during a write cycle.<br>Ao: Byte Select Address. Not used in x16 mode(can be floated).<br>A1-A4: Column Address. Selects 1 of 16 bit lines.<br>A5-A15: Row Address. Selects 1 of 2048 word lines.<br>A16-A21: Block Address.   |  |  |  |  |  |
| DQ <sub>0</sub> -DQ <sub>15</sub>       | INPUT/<br>OUTPUT        | <b>DATA INPUT/OUTPUTS:</b><br>$DQ_0$ - $DQ_7$ :Inputs data and commands during CUI write cycles; outputs data during memory<br>array, status register, query, and identifier code read cycles. Data pins float to high-<br>impedance when the chip is deselected or outputs are disabled. Data is internally latched<br>during a write cycle.<br>$DQ_8$ - $DQ_{15}$ :Inputs data during CUI write cycles in x16 mode; outputs data during memory<br>array read cycles in x16 mode; not used for status register, query and identifier code read<br>mode. Data pins float to high-impedance when the chip is deselected, outputs are<br>disabled, or in x8 mode(Byte#=V <sub>II</sub> ). Data is internally latched during a write cycle. |  |  |  |  |  |
| CE <sub>0</sub> #,<br>CE <sub>1</sub> # | INPUT                   | <b>CHIP ENABLE:</b> Activates the device's control logic, input buffers decoders, and sense amplifiers. Either $CE_0^{\#}$ or $CE_1^{\#} V_{IH}^{\#}$ deselects the device and reduces power consumption to standby levels. Both $CE_0^{\#}$ and $CE_1^{\#}$ must be $V_{II}^{\#}$ to select the devices.  |  |  |  |  |  |
| RP#                                     | INPUT                   | <b>RESET/DEEP POWER-DOWN:</b> Puts the device in deep power-down mode and resets internal automation. RP# V <sub>IH</sub> enables normal operation. When driven V <sub>IL</sub> , RP# inhibits write operations which provides data protection during power transitions. Exit from deep power-down sets the device to read array mode.   |  |  |  |  |  |
| OE#                                     | INPUT                   | OUTPUT ENABLE: Gates the device's outputs during a read cycle.   |  |  |  |  |  |
| WE#                                     | INPUT                   | WRITE ENABLE: Controls writes to the CUI and array blocks. Addresses and data are latched on the rising edge of the WE# pulse.   |  |  |  |  |  |
| STS                                     | OPEN<br>DRAIN<br>OUTPUT | STS (RY/BY#): Indicates the status of the internal WSM. When configured in level mode (default mode), it acts as a RY/BY# pin. When low, the WSM is performing an internal operation (block erase, full chip erase, (multi) word/byte write or block lock-bit configuration). STS High Z indicates that the WSM is ready for new commands, block erase is suspended, and (multi) word/byte write is inactive, (multi) word/byte write is suspended or the device is in deep power-down mode. For alternate configurations of the STATUS pin. see the Configuration command.  |  |  |  |  |  |
| WP#                                     | INPUT                   | WRITE PROTECT: Master control for block locking. When V <sub>IL</sub> . Locked blocks can not be erased and programmed, and block lock-bits can not be set and reset.  |  |  |  |  |  |
| BYTE#                                   | INPUT                   | <b>BYTE ENABLE:</b> BYTE# $V_{1L}$ places device in x8 mode. All data is then input or output on $DQ_{0-7}$ , and $DQ_{8-15}$ float. BYTE# $V_{1H}$ places the device in x16 mode, and turns off the $A_0$ input buffer.   |  |  |  |  |  |
| V <sub>PP</sub>                         | SUPPLY                  | BLOCK ERASE, FULL CHIP ERASE, (MULTI) WORD/BYTE WRITE, BLOCK LOCK-<br>BIT CONFIGURATION POWER SUPPLY: For erasing array blocks, writing bytes or<br>configuring block lock-bits. With $V_{PP} \leq V_{PPLK}$ , memory contents cannot be altered. Block<br>erase, full chip erase, (multi) word/byte write and block lock-bit configuration with an invalid<br>$V_{PP}$ (see DC Characteristics) produce spurious results and should not be attempted.   |  |  |  |  |  |
| v <sub>cc</sub>                         | SUPPLY                  | <b>DEVICE POWER SUPPLY:</b> Internal detection configures the device for 5V operation. Do not float any power pins. With $V_{CC} \leq V_{LKO}$ , all write attempts to the flash memory are inhibited. Device operations at invalid $V_{CC}$ voltage (see DC Characteristics) produce spurious results and should not be attempted.  |  |  |  |  |  |
| GND                                     | SUPPLY                  | GROUND: Do not float any ground pins.  |  |  |  |  |  |
| NC                                      |                         | NO CONNECT: Lead is not internal connected; it may be driven or floated.   |  |  |  |  |  |

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 2 PRINCIPLES OF OPERATION

The LH28F320S5-L90/12 Flash memory includes an on-chip WSM to manage block erase, full chip erase, (multi) word/byte write and block lock-bit configuration functions. It allows for: 100% TTL-level control inputs, fixed power supplies during block erase, full chip erase, (multi) word/byte write and block lock-bit configuration, and minimal processor overhead with RAM-Like interface timings.

After initial device power-up or return from deep power-down mode (see Bus Operations), the device defaults to read array mode. Manipulation of external memory control pins allow array read, standby, and output disable operations.

Status register, query structure and identifier codes can be accessed through the CUI independent of the  $V_{PP}$  voltage. High voltage on  $V_{PP}$  enables successful block erase, full chip erase, (multi) word/byte write and block lock-bit configuration. All functions associated with altering memory contents—block erase, full chip erase, (multi) word/byte write and block lock-bit configuration, status, query and identifier codes—are accessed via the CUI and verified through the status register.

Commands are written using standard microprocessor write timings. The CUI contents serve as input to the WSM, which controls the block erase, full chip erase, (multi) word/byte write and block lockbit configuration. The internal algorithms are regulated by the WSM, including pulse repetition, internal verification, and margining of data. Addresses and data are internally latch during write cycles. Writing the appropriate command outputs array data, accesses the identifier codes, outputs query structure or outputs status register data. Interface software that initiates and polls progress of block erase, full chip erase, (multi) word/byte write and block lock-bit configuration can be stored in any block. This code is copied to and executed from system RAM during flash memory updates. After successful completion, reads are again possible via the Read Array command. Block erase suspend allows system software to suspend a block erase to read or write data from any other block. Write suspend allows system software to suspend a (multi) word/byte write to read data from any other flash memory array location.

### 2.1 Data Protection

Depending on the application, the system designer may choose to make the  $V_{PP}$  power supply switchable (available only when block erase, full chip erase, (multi) word/byte write and block lock-bit configuration are required) or hardwired to  $V_{PPH1}$ . The device accommodates either design practice and encourages optimization of the processor-memory interface.

When  $V_{PP} \leq V_{PPLK}$ , memory contents cannot be altered. The CUI, with multi-step block erase, full chip erase, (multi) word/byte write and block lock-bit configuration command sequences, provides protection from unwanted operations even when high voltage is applied to  $V_{PP}$ . All write functions are disabled when  $V_{CC}$  is below the write lockout voltage  $V_{LKO}$  or when RP# is at  $V_{IL}$ . The device's block locking capability provides additional protection from inadvertent code or data alteration by gating block erase, full chip erase and (multi) word/byte write operations.

Figure 4. Memory Map

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### **3 BUS OPERATION**

The local CPU reads and writes flash memory insystem. All bus cycles to or from the flash memory conform to standard microprocessor bus cycles.

#### 3.1 Read

Information can be read from any block, identifier codes, query structure, or status register independent of the  $V_{PP}$  voltage. RP# must be at  $V_{IH}$ .

The first task is to write the appropriate read mode command (Read Array, Read Identifier Codes, Query or Read Status Register) to the CUI. Upon initial device power-up or after exit from deep power-down mode, the device automatically resets to read array mode. Five control pins dictate the data flow in and out of the component:  $CE\# (CE_0\#, CE_1\#)$ , OE#, WE#, RP# and WP#.  $CE_0\#$ ,  $CE_1\#$  and OE# must be driven active to obtain data at the outputs.  $CE_0\#$ ,  $CE_1\#$  is the device selection control, and when active enables the selected memory device. OE# is the data output ( $DQ_0-DQ_{15}$ ) control and when active drives the selected memory data onto the I/O bus. WE# and RP# must be at V<sub>IH</sub>. Figure 18, 19 illustrates a read cycle.

### 3.2 Output Disable

With OE# at a logic-high level ( $V_{IH}$ ), the device outputs are disabled. Output pins DQ<sub>0</sub>-DQ<sub>15</sub> are placed in a high-impedance state.

### 3.3 Standby

Either  $CE_0$ # or  $CE_1$ # at a logic-high level (V<sub>IH</sub>) places the device in standby mode which substantially reduces device power consumption.  $DQ_0$ - $DQ_{15}$ outputs are placed in a high-impedance state independent of OE#. If deselected during block erase, full chip erase, (multi) word/byte write and block lock-bit configuration, the device continues functioning, and consuming active power until the operation completes.

### 3.4 Deep Power-Down

RP# at V<sub>II</sub> initiates the deep power-down mode.

In read modes, RP#-low deselects the memory, places output drivers in a high-impedance state and turns off all internal circuits. RP# must be held low for a minimum of 100 ns. Time  $t_{PHQV}$  is required after return from power-down until initial memory access outputs are valid. After this wake-up interval, normal operation is restored. The CUI is reset to read array mode and status register is set to 80H.

During block erase, full chip erase, (multi) word/byte write or block lock-bit configuration modes, RP#-low will abort the operation. STS remains low until the reset operation is complete. Memory contents being altered are no longer valid; the data may be partially erased or written. Time  $t_{PHWL}$  is required after RP# goes to logic-high (V<sub>IH</sub>) before another command can be written.

As with any automated device, it is important to assert RP# during system reset. When the system comes out of reset, it expects to read from the flash memory. Automated flash memories provide status information when accessed during block erase, full chip erase, (multi) word/byte write and block lock-bit configuration. If a CPU reset occurs with no flash memory reset, proper CPU initialization may not occur because the flash memory may be providing status information instead of array data. SHARP's flash memories allow proper CPU initialization following a system reset through the use of the RP# input. In this application, RP# is controlled by the same RESET# signal that resets the system CPU.

### 3.5 Read Identifier Codes Operation

The read identifier codes operation outputs the manufacturer code, device code, block status codes for each block (see Figure 5). Using the manufacturer and device codes, the system CPU can automatically match the device with its proper algorithms. The block status codes identify locked or unlocked block setting and erase completed or erase uncompleted condition.

Figure 5. Device Identifier Code Memory Map

### 3.6 Query Operation

The query operation outputs the query structure. Query database is stored in the 48Byte ROM. Query structure allows system software to gain critical information for controlling the flash component. Query structure are always presented on the lowestorder data output ( $DQ_0$ - $DQ_7$ ) only.

#### 3.7 Write

Writing commands to the CUI enable reading of device data and identifier codes. They also control inspection and clearing of the status register. When  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1}$ , the CUI additionally controls block erase, full chip erase, (multi) word/byte write and block lock-bit configuration.

The Block Erase command requires appropriate command data and an address within the block to be erased. The Word/byte Write command requires the command and address of the location to be written. Set Block Lock-Bit command requires the command and block address within the device (Block Lock) to be locked. The Clear Block Lock-Bits command requires the command and address within the device.

The CUI does not occupy an addressable memory location. It is written when WE# and CE# are active. The address and data needed to execute a command are latched on the rising edge of WE# or CE# (whichever goes high first). Standard microprocessor write timings are used. Figures 20 and 21 illustrate WE# and CE#-controlled write operations.

### **4 COMMAND DEFINITIONS**

When the V<sub>PP</sub> voltage  $\leq$  V<sub>PPLK</sub>, Read operations from the status register, identifier codes, query, or blocks are enabled. Placing V<sub>PPH1</sub> on V<sub>PP</sub> enables successful block erase, full chip erase, (multi) word/byte write and block lock-bit configuration operations.

Device operations are selected by writing specific commands into the CUI. Table 4 defines these commands.

#### NOTES:

1. Refer to DC Characteristics. When V<sub>PP</sub> ≤ V<sub>PPI K</sub>, memory contents can be read, but not altered.

2. X can be VIL or VIH for control pins and addresses, and VPPLK or VPPH1 for VPP. See DC Characteristics for  $V_{PPLK}$  and  $\overline{V}_{PPH1}$  voltages.

3. STS is VOL (if configured to RY/BY# mode) when the WSM is executing internal block erase, full chip erase, (multi) word/byte write or block lock-bit configuration algorithms. It is floated during when the WSM is not busy, in block erase suspend mode with (multi) word/byte write inactive, (multi) word/byte write suspend mode, or deep power-down mode.

4. RP# at GND±0.2V ensures the lowest deep power-down current.

5. See Section 4.2 for read identifier code data.

6. See Section 4.5 for query data.

7. Command writes involving block erase, full chip erase, (multi) word/byte write or block lock-bit configuration are reliably executed when  $V_{PP}=V_{PPH1}$  and  $V_{CC}=V_{CC1/2}$ . 8. Refer to Table 4 for valid  $D_{IN}$  during a write operation.

- 9. Don't use the timing both OE# and WE# are V<sub>II</sub>.

#### Table 4. Command Definitions<sup>(10)</sup>

#### NOTES:

- 1. BUS operations are defined in Table 3 and Table 3.1.
- 2. X=Any valid address within the device.

IA=Identifier Code Address: see Figure 5.

QA=Query Offset Address.

BA=Address within the block being erased or locked.

WA=Address of memory location to be written.

3. SRD=Data read from status register. See Table 14 for a description of the status register bits.

WD=Data to be written at location WA. Data is latched on the rising edge of WE# or CE# (whichever goes high first).

ID=Data read from identifier codes.

QD=Data read from query database.

- 4. Following the Read Identifier Codes command, read operations access manufacturer, device and block status codes. See Section 4.2 for read identifier code data.
- If the block is locked, WP# must be at V<sub>IH</sub> to enable block erase or (multi) word/byte write operations. Attempts to issue a block erase or (multi) word/byte write to a locked block while RP# is V<sub>IH</sub>.
- 6. Either 40H or 10H are recognized by the WSM as the byte write setup.
- 7. A block lock-bit can be set while WP# is VIH-
- WP# must be at V<sub>IH</sub> to clear block lock-bits. The clear block lock-bits operation simultaneously clears all block lock-bits.
- 9. Following the Third Bus Cycle, inputs the write address and write data of 'N'+1 times. Finally, input the confirm command 'D0H'.
- 10. Commands other than those shown above are reserved by SHARP for future device implementations and should not be used.

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 4.1 Read Array Command

Upon initial device power-up and after exit from deep power-down mode, the device defaults to read array mode. This operation is also initiated by writing the Read Array command. The device remains enabled for reads until another command is written. Once the internal WSM has started a block erase, full chip erase, (multi) word/byte write or block lock-bit configuration, the device will not recognize the Read Array command until the WSM completes its operation unless the WSM is suspended via an Erase Suspend and (Multi) Word/byte Write Suspend command. The Read Array command functions independently of the V<sub>PP</sub> voltage and RP# must be V<sub>IH</sub>.

### 4.2 Read Identifier Codes Command

The identifier code operation is initiated by writing the Read Identifier Codes command. Following the command write, read cycles from addresses shown in Figure 5 retrieve the manufacturer, device, block lock configuration and block erase status (see Table 5 for identifier code values). To terminate the operation, write another valid command. Like the Read Array command, the Read Identifier Codes command functions independently of the V<sub>PP</sub> voltage and RP# must be V<sub>IH</sub>. Following the Read Identifier Codes command, the following information can be read:

| Code  | Address<br>A20-A0                            | Data               |
|---|--|--------------------|
| Manufacture Code  | 000000<br>000001                             | BO                 |
| Device Code   | 000002<br>000003                             | D4                 |
| Block Status Code   | X0004 <sup>(1)</sup><br>X0005 <sup>(1)</sup> |                    |
| <ul> <li>Block is Unlocked</li> </ul>                                       |  | DQ <sub>0</sub> =0 |
| <ul> <li>Block is Locked</li> </ul>   |  | DQ <sub>0</sub> =1 |
| <ul> <li>Last erase operation<br/>completed successfully</li> </ul>         |  | DQ <sub>1</sub> =0 |
| <ul> <li>Last erase operation did<br/>not completed successfully</li> </ul> |  | DQ <sub>1</sub> =1 |
| <ul> <li>Reserved for Future Use</li> </ul>                                 |  | DQ <sub>2-7</sub>  |

Table 5. Identifier Codes

NOTE:

14

 X selects the specific block status code to be read. See Figure 5 for the device identifier code memory map.

### 4.3 Read Status Register Command

The status register may be read to determine when a block erase, full chip erase, (multi) word/byte write or block lock-bit configuration is complete and whether the operation completed successfully(see Table 14). It may be read at any time by writing the Read Status Register command. After writing this command, all subsequent read operations output data from the status register until another valid command is written. The status register contents are latched on the falling edge of OE# or CE#(Either CE<sub>0</sub># or CE<sub>1</sub>#), whichever occurs. OE# or CE#(Either CE<sub>0</sub># or CE<sub>1</sub>#) must toggle to V<sub>IH</sub> before further reads to update the status register latch. The Read Status Register command functions independently of the V<sub>PP</sub> voltage. RP# must be V<sub>IH</sub>.

The extended status register may be read to determine multi byte write availability(see Table 14.1). The extended status register may be read at any time by writing the Multi Byte Write command. After writing this command, all subsequent read operations output data from the extended status register, until another valid command is written. The contents of the extended status register are latched on the falling edge of OE# or CE#(Either CE<sub>0</sub># or CE<sub>1</sub>#), whichever occurs last in the read cycle. Multi Byte Write command must be re-issued to update the extended status register latch.

### 4.4 Clear Status Register Command

Status register bits SR.5, SR.4, SR.3 and SR.1 are set to "1"s by the WSM and can only be reset by the Clear Status Register command. These bits indicate various failure conditions (see Table 14). By allowing system software to reset these bits, several operations (such as cumulatively erasing or locking multiple blocks or writing several bytes in sequence) may be performed. The status register may be polled to determine if an error occurs during the sequence.

To clear the status register, the Clear Status Register command (50H) is written. It functions independently of the applied  $V_{PP}$  Voltage. RP# must be  $V_{IH}$ . This command is not functional during block erase, full chip erase, (multi) word/byte write block lock-bit configuration, block erase suspend or (multi) word/byte write suspend modes.

SHARP

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

#### 4.5 Query Command

Query database can be read by writing Query command (98H). Following the command write, read cycle from address shown in Table 7~11 retrieve the critical information to write, erase and otherwise control the flash component.  $A_0$  of query offset address is ignored when X8 mode (BYTE#=V<sub>IL</sub>).

Query data are always presented on the low-byte data output  $(DQ_0-DQ_7)$ . In x16 mode, high-byte  $(DQ_8-DQ_{15})$  outputs 00H. The bytes not assigned to any information or reserved for future use are set to "0". This command functions independently of the V<sub>PP</sub> voltage. RP# must be V<sub>IH</sub>.

| Table 6. | Example of Query S | tructure Output |
|----------|--------------------|-----------------|
| Mada     | Offeet Address     | Outrout         |

| Mode     | Offset Address  | Output             |             |  |
|----------|---|--------------------|-------------|--|
|          |   | DQ <sub>15~8</sub> | $DQ_{7-0}$  |  |
|          | A <sub>5</sub> , A <sub>4</sub> , A <sub>3</sub> , A <sub>2</sub> , A <sub>1</sub> , A <sub>0</sub> |                    |             |  |
|          | 1, 0, 0, 0, 0, 0, 0 (20H)   | High-Z             | <b>"</b> Q" |  |
| X8 mode  | 1,0,0,0,0,1(21H)  | High-Z             | "Q"         |  |
|          | 1, 0,0,0,1,0(22H)   | High-Z             | "R"         |  |
|          | 1,0,0,0,1,1(23H)  | High-Z             | "R"         |  |
|          | A <sub>5</sub> , A <sub>4</sub> , A <sub>3</sub> , A <sub>2</sub> , A <sub>1</sub>                  |                    |             |  |
| X16 mode | 1,0,0,0,0,0(10H)  | 00H                | "Q"         |  |
|          | 1,0,0,0,1 (11H)   | 00H                | "R"         |  |

#### 4.5.1 Block Status Register

This field provides lock configuration and erase status for the specified block. These informations are only available when device is ready (SR.7=1). If block erase or full chip erase operation is finished irregulary, block erase status bit will be set to "1". If bit 1 is "1", this block is invalid.

| Offset<br>(Word Address) | Length | Description   | - |
|--------------------------|--------|---|---|
| (BA+2)H                  | 01H    | Block Status Register         bit0       Block Lock Configuration         0=Block is unlocked         1=Block is Locked         bit1       Block Erase Status         0=Last erase operation completed successfully         1=Last erase operation not completed successfully |   |
|                          |        |   |   |

Table 7. Query Block Status Register

Note:

1. BA=The beginning of a Block Address.

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 4.5.2 CFI Query Identification String

The Identification String provides verification that the component supports the Common Flash Interface specification. Additionally, it indicates which version of the spec and which Vendor-specified command set(s) is(are) supported.

| Offset<br>(Word Address) | Length | Description  |  |
|--------------------------|--------|--|--|
| 10H,11H,12H              | 03H    | Query Unique ASCII string "QRY"<br>51H,52H,59H   |  |
| 13H,14H                  | 02H    | Primary Vendor Command Set and Control Interface ID Code<br>01H,00H (SCS ID Code)                          |  |
| 15H,16H                  | 02H    | Address for Primary Algorithm Extended Query Table<br>31H,00H (SCS Extended Query Table Offset)            |  |
| 17H,18H                  | 02H    | Alternate Vendor Command Set and Control Interface ID Code<br>0000H (0000H means that no alternate exists) |  |
| 19H,1AH                  | 02H    | Address for Alternate Algorithm Extended Query Table<br>0000H (0000H means that no alternate exists)       |  |

| Table 8. CFI | Query Id | entification | String |
|--------------|----------|--------------|--------|
|              |          |              |        |

### 4.5.3 System Interface Information

The following device information can be useful in optimizing system interface software.

| Offset<br>(Word Address) | Length | Description   |
|--------------------------|--------|---|
| 1BH                      | 01H    | V <sub>CC</sub> Logic Supply Minimum Write/Erase voltage<br>45H (4.5V)  |
| 1CH                      | 01H    | V <sub>CC</sub> Logic Supply Maximum Write/Erase voltage<br>55H (5.5V)  |
| 1DH                      | 01H    | V <sub>PP</sub> Programming Supply Minimum Write/Erase voltage<br>45H (4.5V)  |
| 1EH                      | 01H    | V <sub>PP</sub> Programming Supply Maximum Write/Erase voltage<br>55H (5.5V)  |
| 1FH                      | 01H    | Typical Timeout per Single Byte/Word Write<br>04H (2 <sup>4</sup> =16 µsec)   |

### Table 11. SCS OEM Specific Extended Query Table

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 4.6 Block Erase Command

Block erase is executed one block at a time and initiated by a two-cycle command. A block erase setup is first written, followed by an block erase confirm. This command sequence requires appropriate sequencing and an address within the block to be erased (erase changes all block data to FFH). Block preconditioning, erase and verify are handled internally by the WSM (invisible to the system). After the two-cycle block erase sequence is written, the device automatically outputs status register data when read (see Figure 6). The CPU can detect block erase completion by analyzing the output data of the STS pin or status register bit SR.7.

When the block erase is complete, status register bit SR.5 should be checked. If a block erase error is detected, the status register should be cleared before system software attempts corrective actions. The CUI remains in read status register mode until a new command is issued.

This two-step command sequence of set-up followed by execution ensures that block contents are not accidentally erased. An invalid Block Erase command sequence will result in both status register bits SR.4 and SR.5 being set to "1". Also, reliable block erasure can only occur when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1}$ . In the absence of this high voltage, block contents are protected against erasure. If block erase is attempted while  $V_{PP} \leq V_{PPLK}$ , SR.3 and SR.5 will be set to "1". Successful block erase requires that the corresponding block lock-bit be cleared or if set, that WP#=V<sub>1H</sub>. If block erase is attempted when the corresponding block lock-bit is set and WP#=VIII, SR.1 and SR.5 will be set to "1".

### 4.7 Full Chip Erase Command

This command followed by a confirm command (D0H) erases all of the unlocked blocks. A full chip

erase setup is first written, followed by a full chip erase confirm. After a confirm command is written, device erases the all unlocked blocks from block 0 to Block 63 block by block. This command sequence requires appropriate sequencing. Block preconditioning, erase and verify are handled internally by the WSM (invisible to the system). After the two-cycle full chip erase sequence is written, the device automatically outputs status register data when read (see Figure 7). The CPU can detect full chip erase completion by analyzing the output data of the STS pin or status register bit SR.7.

When the full chip erase is complete, status register bit SR.5 should be checked. If erase error is detected, the status register should be cleared before system software attempts corrective actions. The CUI remains in read status register mode until a new command is issued. If error is detected on a block during full chip erase operation, WSM stops erasing the block and begin to erase the next block. Reading the block valid status by issuing Read ID Codes command or Query command informs which blocks failed to its erase.

This two-step command sequence of set-up followed by execution ensures that block contents are not accidentally erased. An invalid Full Chip Erase command sequence will result in both status register bits SR.4 and SR.5 being set to "1". Also, reliable full chip erasure can only occur when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1}$ . In the absence of this high voltage, block contents are protected against erasure. If full chip erase is attempted while  $V_{PP}\leq V_{PPLK}$ , SR.3 and SR.5 will be set to "1". When  $WP\#=V_{1H}$ , all blocks are erased independent of block lock-bits status. When  $WP\#=V_{1L}$ , only unlocked blocks are erased. Full chip erase can not be suspended.

### 4.8 Word/Byte Write Command

Word/byte write is executed by a two-cycle command sequence. Word/Byte Write setup (standard 40H or alternate 10H) is written, followed by a second write that specifies the address and data (latched on the rising edge of WE#). The WSM then takes over, controlling the word/byte write and write verify algorithms internally. After the word/byte write sequence is written, the device automatically outputs status register data when read (see Figure 8). The CPU can detect the completion of the word/byte write event by analyzing the STS pin or status register bit SR.7.

When word/byte write is complete, status register bit SR.4 should be checked. If word/byte write error is detected, the status register should be cleared. The internal WSM verify only detects errors for "1"s that do not successfully write to "0"s. The CUI remains in read status register mode until it receives another command.

Reliable word/byte writes can only occur when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1}$ . In the absence of this high voltage, memory contents are protected against word/byte writes. If word/byte write is attempted while  $V_{PP}\leq V_{PPLK}$ , status register bits SR.3 and SR.4 will be set to "1". Successful word/byte write requires that the corresponding block lock-bit be cleared or, if set, that WP#=V<sub>IH</sub>. If word/byte write is attempted when the corresponding block lock-bit is set and WP#=V<sub>IL</sub>, SR.1 and SR.4 will be set to "1". Word/byte write operations with  $V_{IL} < WP# < V_{IH}$  produce spurious results and should not be attempted.

#### 4.9 Multi Word/Byte Write Command

Multi word/byte write is executed by at least fourcycle or up to 35-cycle command sequence. Up to 32 bytes in x8 mode (16 words in x16 mode) can be loaded into the buffer and written to the Flash Array. First, multi word/byte write setup (E8H) is written with the write address. At this point, the device automatically outputs extended status register data (XSR) when read (see Figure 9, 10). If extended status register bit XSR.7 is 0, no Multi Word/Byte Write command is available and multi word/byte write setup which just has been written is ignored. To retry,

continue monitoring XSR.7 by writing multi word/byte write setup with write address until XSR.7 transitions to 1. When XSR.7 transitions to 1, the device is ready for loading the data to the buffer. A word/byte count (N) is written with write address. After writing a word/byte count(N), the device automatically turns back to output status register data. The word/byte count (N) must be less than or equal to 1FH in x8 mode (0FH in x16 mode). On the next write, device start address is written with buffer data. Subsequent writes provide additional device address and data, depending on the count. All subsequent address must lie within the start address plus the count. After the final buffer data is written, write confirm (DOH) must be written. This initiates WSM to begin copying the buffer data to the Flash Array. An invalid Multi Word/Byte Write command sequence will result in both status register bits SR.4 and SR.5 being set to "1". For additional multi word/byte write, write another multi word/byte write setup and check XSR.7. The Multi Word/Byte Write command can be queued while WSM is busy as long as XSR.7 indicates "1", because LH28F320S5-L90/12 has two buffers. If an error occurs while writing, the device will stop writing and flush next multi word/byte write command loaded in multi word/byte write command. Status register bit SR.4 will be set to "1". No multi word/byte write command is available if either SR.4 or SR.5 are set to "1". SR.4 and SR.5 should be cleared before issuing multi word/byte write command. If a multi word/byte write command is attempted past an erase block boundary, the device will write the data to Flash Array up to an erase block boundary and then stop writing. Status register bits SR.4 and SR.5 will be set to "1".

Reliable multi byte writes can only occur when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1}$ . In the absence of this high voltage, memory contents are protected against multi word/byte writes. If multi word/byte write is attempted while  $V_{PP}\leq V_{PPLK}$ , status register bits SR.3 and SR.4 will be set to "1". Successful multi word/byte write requires that the corresponding block lock-bit be cleared or, if set, that  $WP\#=V_{1H}$ . If multi byte write is attempted when the corresponding block lock-bit is set and  $WP\#=V_{1L}$ , SR.1 and SR.4 will be set to "1".

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 4.10 Block Erase Suspend Command

The Block Erase Suspend command allows blockerase interruption to read or (multi) word/byte-write data in another block of memory. Once the blockerase process starts, writing the Block Erase Suspend command requests that the WSM suspend the block erase sequence at a predetermined point in the algorithm. The device outputs status register data when read after the Block Erase Suspend command is written. Polling status register bits SR.7 and SR.6 can determine when the block erase operation has been suspended (both will be set to "1"). STS will also transition to High-Z. Specification  $t_{WHRH2}$ defines the block erase suspend latency.

At this point, a Read Array command can be written to read data from blocks other than that which is suspended. A (Multi) Word/Byte Write command sequence can also be issued during erase suspend to program data in other blocks. Using the (Multi) Word/Byte Write Suspend command (see Section 4.11), a (multi) word/byte write operation can also be suspended. During a (multi) word/byte write operation with block erase suspended, status register bit SR.7 will return to "0" and the STS (if set to RY/BY#) output will transition to  $V_{OL}$ . However, SR.6 will remain "1" to indicate block erase suspend status.

The only other valid commands while block erase is suspended are Read Status Register and Block Erase Resume. After a Block Erase Resume command is written to the flash memory, the WSM will continue the block erase process. Status register bits SR.6 and SR.7 will automatically clear and STS will return to  $V_{OL}$ . After the Erase Resume command is written, the device automatically outputs status register data when read (see Figure 11).  $V_{PP}$  must remain at  $V_{PPH1}$  (the same  $V_{PP}$  level used for block erase) while block erase is suspended. RP# must also remain at  $V_{IH}$ . Block erase cannot resume until

(multi) word/byte write operations initiated during block erase suspend have completed.

### 4.11 (Multi) Word/Byte Write Suspend Command

The (Multi) Word/Byte Write Suspend command allows (multi) word/byte write interruption to read data in other flash memory locations. Once the (multi) word/byte write process starts, writing the (Multi) Word/Byte Write Suspend command requests that the WSM suspend the (multi) word/byte write sequence at a predetermined point in the algorithm. The device continues to output status register data when read after the (Multi) Word/Byte Write Suspend command is written. Polling status register bits SR.7 and SR.2 can determine when the (multi) word/byte write operation has been suspended (both will be set to "1"). STS will also transition to High-Z. Specification  $t_{WHRH1}$  defines the (multi) word/byte write suspend latency.

At this point, a Read Array command can be written to read data from locations other than that which is suspended. The only other valid commands while (multi) word/byte write is suspended are Read Status Register and (Multi) Word/Byte Write Resume. After (Multi) Word/Byte Write Resume command is written to the flash memory, the WSM will continue the (multi) word/byte write process. Status register bits SR.2 and SR.7 will automatically clear and STS will return to V<sub>OL</sub>. After the (Multi) Word/Byte Write command is written, the device automatically outputs status register data when read (see Figure 12). VPP must remain at VPPH1 (the same VPP level used for (multi) word/byte write) while in (multi) word/byte write suspend mode. WP# must also remain at VIH or  $V_{\rm HL}$ .

20

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

#### 4.12 Set Block Lock-Bit Command

A flexible block locking and unlocking scheme is enabled via block lock-bits. The block lock-bits gate program and erase operations With  $WP\#=V_{IH}$ , individual block lock-bits can be set using the Set Block Lock-Bit command. See Table 13 for a summary of hardware and software write protection options.

Set block lock-bit is executed by a two-cycle command sequence. The set block lock-bit setup along with appropriate block or device address is written followed by either the set block lock-bit confirm (and an address within the block to be locked). The WSM then controls the set block lock-bit algorithm. After the sequence is written, the device automatically outputs status register data when read (see Figure 13). The CPU can detect the completion of the set block lock-bit event by analyzing the STS pin output or status register bit SR.7.

When the set block lock-bit operation is complete, status register bit SR.4 should be checked. If an error is detected, the status register should be cleared. The CUI will remain in read status register mode until a new command is issued.

This two-step sequence of set-up followed by execution ensures that block lock-bits are not accidentally set. An invalid Set Block Lock-Bit command will result in status register bits SR.4 and SR.5 being set to "1". Also, reliable operations occur only when  $V_{CC}=V_{CC1/2}$  and  $V_{PP}=V_{PPH1}$ . In the absence of this high voltage, block lock-bit contents are protected against alteration.

A successful set block lock-bit operation requires  $WP\#=V_{IH}$ . If it is attempted with  $WP\#=V_{IL}$ , SR.1 and SR.4 will be set to "1" and the operation will fail. Set block lock-bit operations with  $WP\#=V_{IH}$  produce spurious results and should not be attempted.

#### 4.13 Clear Block Lock-Bits Command

All set block lock-bits are cleared in parallel via the Clear Block Lock-Bits command. With  $WP#=V_{1H}$ ,

block lock-bits can be cleared using only the Clear Block Lock-Bits command. See Table 13 for a summary of hardware and software write protection options.

Clear block lock-bits operation is executed by a twocycle command sequence. A clear block lock-bits setup is first written. After the command is written, the device automatically outputs status register data when read (see Figure 14). The CPU can detect completion of the clear block lock-bits event by analyzing the STS Pin output or status register bit SR.7.

When the operation is complete, status register bit SR.5 should be checked. If a clear block lock-bit error is detected, the status register should be cleared. The CUI will remain in read status register mode until another command is issued.

This two-step sequence of set-up followed by execution ensures that block lock-bits are not accidentally cleared. An invalid Clear Block Lock-Bits command sequence will result in status register bits SR.4 and SR.5 being set to "1". Also, a reliable clear block lock-bits operation can only occur when V<sub>CC</sub>=V<sub>CC1/2</sub> and V<sub>PP</sub>=V<sub>PPH1</sub>. If a clear block lock+bits operation is attempted while V<sub>PP</sub>≤V<sub>PPLK</sub>, SR.3 and SR.5 will be set to "1". In the absence of this high voltage, the block lock-bits content are protected against alteration. A successful clear block lock-bits operation requires WP#=VIH. If it is attempted with WP#=VII, SR.1 and SR.5 will be set to "1" and the operation will fail. Clear block lock-bits operations with V<sub>1H</sub><RP# produce spurious results and should not be attempted.

If a clear block lock-bits operation is aborted due to  $V_{PP}$  or  $V_{CC}$  transitioning out of valid range or RP# active transition, block lock-bit values are left in an undetermined state. A repeat of clear block lock-bits is required to initialize block lock-bit contents to known values.

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 4.14 STS Configuration Command

The Status (STS) pin can be configured to different states using the STS Configuration command. Once the STS pin has been configured, it remains in that configuration until another configuration command is issued, the device is powered down or RP# is set to V<sub>IL</sub>. Upon initial device power-up and after exit from deep power-down mode, the STS pin defaults to RY/BY# operation where STS low indicates that the WSM is busy. STS High Z indicates that the WSM is ready for a new operation.

To reconfigure the STS pin to other modes, the STS Configuration is issued followed by the appropriate configuration code. The three alternate configurations are all pulse mode for use as a system interrupt. The STS Configuration command functions independently of the  $V_{PP}$  voltage and RP# must be  $V_{IH}$ .

| Configuration<br>Bits | Effects  |
|-----------------------|--|
| оон                   | Set STS pin to default level mode<br>(RY/BY#). RY/BY# in the default<br>level-mode of operation will indicate<br>WSM status condifion.   |
| 01H                   | Set STS pin to pulsed output signal<br>for specific erase operation. In this<br>mode, STS provides low pulse at<br>the completion of BLock Erase,<br>Full Chip Erase and Clear Block<br>Lock-bits operations.                                |
| 02H                   | Set STS pin to pulsed output signal<br>for a specific write operation. In this<br>mode, STS provides low pulse at<br>the completion of (Multi) Byte Write<br>and Set Block Lock-bit operation.   |
| 03Н                   | Set STS pin to pulsed output signal<br>for specific write and erase<br>operation. STS provides low pulse<br>at the completion of Block Erase,<br>Full Chip Erase, (Multi) Word/Byte<br>Write and Block Lock-bit<br>Configuration operations. |

#### Table 13. Write Protection Alternatives

| Operation                  | Block<br>Lock-Bit | WP#                                | Effect  |

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### **5 DESIGN CONSIDERATIONS**

#### 5.1 Three-Line Output Control

The device will often be used in large memory arrays. SHARP provides three control inputs to accommodate multiple memory connections. Three-Line control provides for:

- a. Lowest possible memory power dissipation.
- b. Complete assurance that data bus contention will not occur.

To use these control inputs efficiently, an address decoder should enable CE# while OE# should be connected to all memory devices and the system's READ# control line. This assures that only selected memory devices have active outputs while deselected memory devices are in standby mode. RP# should be connected to the system POWERGOOD signal to prevent unintended writes during system power transitions. POWERGOOD should also toggle during system reset.

### 5.2 STS and Block Erase, Full Chip Erase, (Multi) Word/Byte Write and Block Lock-Bit Configuration Polling

STS is an open drain output that should be connected to  $V_{CC}$  by a pullup resistor to provide a hardware method of detecting block erase, full chip erase, (multi) word/byte write and block lock-bit configuration completion. In default mode, it transitions low after block erase, full chip erase, (multi) word/byte write or block lock-bit configuration commands and returns to  $V_{OH}$  when the WSM has finished executing the internal algorithm. For alternate STS pin configurations, see the Configuration command.

STS can be connected to an interrupt input of the system CPU or controller. It is active at all times.

STS, in default mode, is also High-Z when the device is in block erase suspend (with (multi) word/byte write inactive), (multi) word/byte write suspend or deep power-down modes.

### 5.3 Power Supply Decoupling

Flash memory power switching characteristics require careful device decoupling. System designers are interested in three supply current issues; standby current levels, active current levels and transient peaks produced by falling and rising edges of CE# and OE#. Transient current magnitudes depend on the device outputs' capacitive and inductive loading. Two-line control and proper decoupling capacitor selection will suppress transient voltage peaks. Each device should have a 0.1 µF ceramic capacitor connected between its  $\mathsf{V}_{\mathsf{CC}}$  and GND and between its VPP and GND. These high-frequency, low inductance capacitors should be placed as close as possible to package leads. Additionally, for every eight devices. a 4.7 µF electrolytic capacitor should be placed at the array's power supply connection between V<sub>CC</sub> and GND. The bulk capacitor will overcome voltage slumps caused by PC board trace inductance.

### 5.4 V<sub>PP</sub> Trace on Printed Circuit Boards

Updating flash memories that reside in the target system requires that the printed circuit board designer pay attention to the  $V_{PP}$  Power supply trace. The  $V_{PP}$  pin supplies the memory cell current for block erase, full chip erase, (multi) word/byte write and block lock-bit configuration. Use similar trace widths and layout considerations given to the  $V_{CC}$  power bus. Adequate  $V_{PP}$  supply traces and decoupling will decrease  $V_{PP}$  voltage spikes and overshoots.

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 5.5 V<sub>CC</sub>, V<sub>PP</sub>, RP# Transitions

Block erase, full chip erase, (multi) word/byte write and block lock-bit configuration are not guaranteed if VPP fails outside of a valid VPPH1 range, VCC fails outside of a valid V<sub>CC1/2</sub> range, or RP#=V<sub>IL</sub>. If V<sub>PP</sub> error is detected, status register bit SR.3 is set to "1" along with SR.4 or SR.5, depending on the attempted operation. If RP# transitions to V<sub>II</sub> during block erase, full chip erase, (multi) word/byte write or block lock-bit configuration, STS(if set to RY/BY# mode) will remain low until the reset operation is complete. Then, the operation will abort and the device will enter deep power-down. The aborted operation may leave data partially altered. Therefore, the command sequence must be repeated after normal operation is restored. Device power-off or RP# transitions to V<sub>II</sub> clear the status register.

The CUI latches commands issued by system software and is not altered by  $V_{PP}$  or CE# transitions or WSM actions. Its state is read array mode upon power-up, after exit from deep power-down or after  $V_{CC}$  transitions below  $V_{LKO}$ .

After block erase, full chip erase, (multi) word/byte write or block lock-bit configuration, even after  $V_{PP}$  transitions down to  $V_{PPLK}$ , the CUI must be placed in read array mode via the Read Array command if subsequent access to the memory array is desired.

### 5.6 Power-Up/Down Protection

The device is designed to offer protection against accidental block and full chip erasure, (multi) word/byte writing or block lock-bit configuration during power transitions. Upon power-up, the device is indifferent as to which power supply (V<sub>PP</sub> or V<sub>CC</sub>)

powers-up first. Internal circuitry resets the CUI to read array mode at power-up.

A system designer must guard against spurious writes for V<sub>CC</sub> voltages above V<sub>LKO</sub> when V<sub>PP</sub> is active. Since both WE# and CE# must be low for a command write, driving either to V<sub>IH</sub> will inhibit writes. The CUI's two-step command sequence architecture provides added level of protection against data alteration.

In-system block lock and unlock capability prevents inadvertent data alteration. The device is disabled while  $RP\#=V_{II}$  regardless of its control inputs state.

#### 5.7 Power Dissipation

When designing portable systems, designers must consider battery power consumption not only during device operation, but also for data retention during system idle time. Flash memory's nonvolatility increases usable battery life because data is retained when system power is removed.

In addition, deep power-down mode ensures extremely low power consumption even when system power is applied. For example, portable computing products and other power sensitive applications that use an array of devices for solid-state storage can consume negligible power by lowering RP# to  $V_{IL}$  standby or sleep modes. If access is again needed, the devices can be read following the  $t_{PHQV}$  and  $t_{PHWL}$  wake-up cycles required after RP# is first raised to  $V_{IH}$ . See AC Characteristics— Read Only and Write Operations and Figures 18, 19, 20, 21 for more information.

**NOTICE:** This datasheet contains information on products in the design phase of development. Do not finalize a design with this information. Revised information will be published when the product is available. Verify with your local SHARP Sales office that you have the latest datasheet before finalizing a design.

\*WARNING: Stressing the device beyond the "Absolute Maximum Ratings" may cause permanent damage. These are stress ratings only. Operation beyond the "Operating Conditions" is not recommended and extended exposure beyond the "Operating Conditions" may affect device reliability.

#### NOTES:

- 1. Operating temperature is for commercial product defined by this specification.
- 2. All specified voltages are with respect to GND. Minimum DC voltage is -0.5V on input/output pins and -0.2V on  $V_{CC}$  and  $V_{PP}$  pins. During transitions, this level may undershoot to -2.0V-for periods <20ns. Maximum DC voltage on input/output pins and  $V_{CC}$  is  $V_{CC}$ +0.5V which, during transitions, may overshoot to  $V_{CC}$ +2.0V for periods <20ns.
- Output shorted for no more than one second. No more than one output shorted at a time.

#### 6.2 Operating Conditions

| Temperature and V <sub>CC</sub> Operating Conditions |   |      |      |      |                     |

#### ----

NOTES:

1. All currents are in RMS unless otherwise noted. Typical values at nominal  $V_{CC}$  voltage and  $T_A$ =+25°C.These currents are valid for all product versions (packages and speeds).

2. I<sub>CCWS</sub> and I<sub>CCES</sub> are specified with the device de-selected. If read or byte written while in erase suspend mode, the device's current draw is the sum of  $I_{CCWS}$  or  $I_{CCES}$  and  $I_{CCR}$  or  $I_{CCW}$ , respectively.

3. Includes STS.

4. Block erases, full chip erases, (multi) word/byte writes and block lock-bit configurations are inhibited when V<sub>PP</sub>≤V<sub>PPLK</sub>, and not guaranteed in the range between V<sub>PPLK</sub>(max) and V<sub>PPH1</sub>(min) and above V<sub>PPH1</sub>(max).

5. Automatic Power Savings (APS) reduces typical  $I_{CCR}$  to 1mA at 5V V<sub>CC</sub> in static operation. 6. CMOS inputs are either V<sub>CC</sub>±0.2V or GND±0.2V. TTL inputs are either V<sub>IL</sub> or V<sub>IH</sub>.

7. Sampled, not 100% tested.

### NOTES:

1. Read timing characteristics during block erase, full chip erase, (multi) wrod/byte write and block lock-bit configuration operations are the same as during read-only operations. Refer to AC Characteristics for read-only operations.

- 2. Sampled, not 100% tested.
- 3. Refer to Table 4 for valid A<sub>IN</sub> and D<sub>IN</sub> for block erase, full chip erase, (multi) word/byte write or block lock-bit configuration.
- 4. V<sub>PP</sub> should be held at V<sub>PPH1</sub> until determination of block erase, full chip erase, (multi) word/byte write or block lock-bit configuration success (SR.1/3/4/5=0).

5. See Ordering Information for device speeds (valid operational combinations).

6. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (High Seed Configuration) for testing characteristics.

7. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (Standard Configuration) for testing characteristics.

### V<sub>CC</sub>=5V±0.5V, 5V±0.25V, T<sub>A</sub>=0°C to +70°C

NOTES:

1. In systems where CE# defines the write pulse width (within a longer WE# timing waveform), all setup, hold and inactive WE# times should be measured relative to the CE# waveform.

2. Sampled, not 100% tested.

3. Refer to Table 4 for valid A<sub>IN</sub> and D<sub>IN</sub> for block erase, full chip erase, (multi) word/byte write or block lock-bit configuration.

 V<sub>PP</sub> should be held at V<sub>PPH1</sub> until determination of block erase, full chip erase, (multi) word/byte write or block lock-bit configuration success (SR.1/3/4/5=0).

5. See Ordering Information for device speeds (valid operational combinations).

6. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (High Seed Configuration) for testing characteristics.

7. See Transient Input/Output Reference Waveform and Transient Equivalent Testing Load Circuit (Standard Configuration) for testing characteristics.

### LH28F320S5-L90/12 Smart 5 Flash MEMORY

### 6.2.7 RESET OPERATIONS

Figure 22. AC Waveform for Reset Operation

| Reset | AC Spec | ifications <sup>(1)</sup> |
|-------|---------|---------------------------|
|       |         |                           |

|                   |  | 1 1   | Vcc  |      |      |
|-------------------|--|-------|------|------|------|
| Symbol            | Parameter  | Notes | Min. | Max. | Unit |
| t <sub>PLPH</sub> | RP# Pulse Low Time<br>(If RP# is tied to V <sub>CC</sub> , this specification is not applicable)                 |       | 100  |      | ns   |
| <sup>t</sup> PLRH | RP# Low to Reset during Block Erase, Full Chip Erase,<br>(Multi) Word/Byte Write or Block Lock-Bit Configuration | 2,3   |      | 13.1 | μs   |
| t <sub>SVPH</sub> | V <sub>CC</sub> at 4.5V to RP# High  | 4     |      | 50   | μs   |

NOTES:

1. These specifications are valid for all product versions (packages and speeds).

2. If RP# is asserted while a block erase, full chip erase, (multi) word/byte write or block lock-bit configuration operation is not executing, the reset will complete within 100ns.

 A reset time, t<sub>PHQV</sub>, is required from the latter of STS going High Z or RP# going high until outputs are valid.
 When the device power-up, holding RP# low minimum 100ns is required after V<sub>CC</sub> has been in predefined range and also has been in stable there.

### V<sub>CC</sub>=5V±0.5V, 5V±0.25V, T<sub>A</sub>=0°C to +70°C

NOTES:

Г

 Typical values measured at T<sub>A</sub>=+25°C and nominal voltages. Assumes corresponding block lock-bits are not set. Subject to change based on device characterization.

2. Excludes system-level overhead.

3. These performance numbers are valid for all speed versions.

4. Sampled but not 100% tested.
