INTEGRATED CIRCUITS

DATA SHEET

TZA3030 SDH/SONET STM1/OC3 optical receiver

Objective specification
File under Integrated Circuits, IC19

1998 Aug 24

TZA3030

FEATURES

- Low equivalent input noise, typically 1 pA/√Hz
- Wide dynamic range, typically 0.5 μA to 2 mA
- On-chip low-pass filter. The bandwidth can be varied between 90 and 150 MHz using an external resistor. Default value is 120 MHz.
- Differential transimpedance of 1.8 $M\Omega$
- On-chip Automatic Gain Control (AGC)
- Positive Emitter Coupled Logic (PECL) or Current-Mode Logic (CML) compatible data outputs
- LOS (Loss Of Signal) detection
- LOS threshold level can be adjusted using a single external resistor
- On-chip DC offset compensation
- Single supply voltage from 3.0 to 5.5 V
- · Bias voltage for PIN diode.

APPLICATIONS

- Digital fibre optic receiver in short, medium and long haul optical telecommunications transmission systems or in high speed data networks
- · Wideband RF gain block.

GENERAL DESCRIPTION

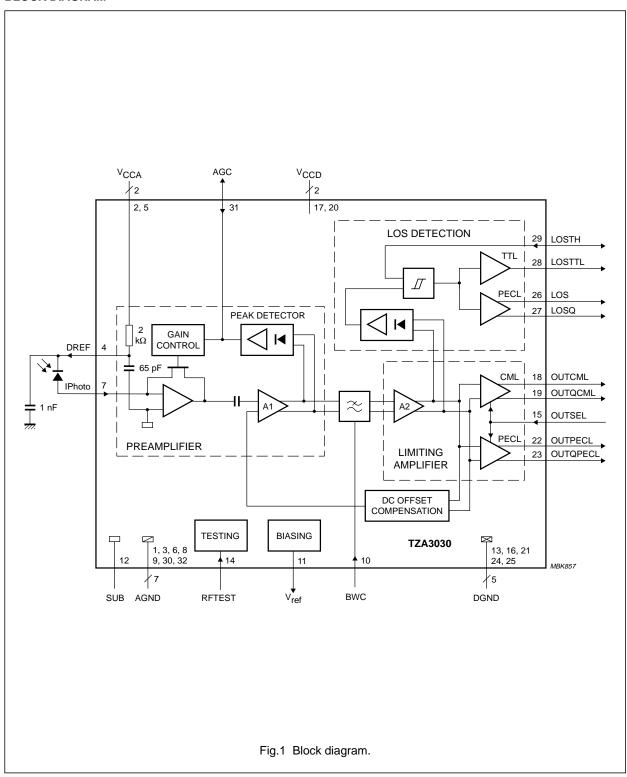

The TZA3030 optical receiver is a low-noise transimpedance amplifier with AGC plus a limiting amplifier designed to be used in SDH/SONET fibre optic links. The TZA3030 amplifies the current generated by a photo detector (PIN diode or avalanche photodiode) and converts it to a differential output voltage.

SDH/SONET STM1/OC3 optical receiver

TZA3030

FUNCTIONAL DESCRIPTION

The TZA3030 contains five functional blocks:

- · Preamplifier input stage
- Low-pass filter
- Limiting amplifier stage
- · Offset compensation loop
- · Loss of signal detection unit.

Preamplifier

The preamplifier provides low-noise amplification of the current generated by a photodiode connected to pin IPhoto.

A differential amplifier converts the output of the preamplifier to a differential voltage. An AGC loop increases the dynamic range of the receiver by reducing the feedback resistance of the preamplifier. The AGC loop hold capacitor is integrated on-chip, so an external capacitor is not needed for AGC. The AGC voltage can be monitored at pin AGC. This pin can be left unconnected for normal operation. It can also be used to force an external AGC voltage. If pin AGC is connected to $V_{\rm CCA}$, the internal AGC loop is disabled and the receiver gain is at a maximum. In this case, the maximum input current is approximately 10 μ A.

Low-pass filter

A low-pass filter controls the bandwidth of the receiver, which can be varied between 90 and 150 MHz. The bandwidth is set to 120 MHz by default. It can be decreased by connecting a resistor between pin BWC and pin V_{ref} or increased by connecting a resistor between pin BWC and AGND.

Limiting amplifier

A limiting amplifier boosts the signal up to PECL levels. The output can be either CML or PECL compatible, selected by means of pin OUTSEL. When OUTSEL is HIGH, the CML data outputs are active and the PECL data outputs are disabled. If OUTSEL is left unconnected, it is pulled LOW and the PECL data outputs are active while the CML data outputs are disabled.

The logic level symbol definitions for CML and PECL are shown in Fig.4.

The CML and PECL output circuits are given in Fig.5.

Offset compensation loop

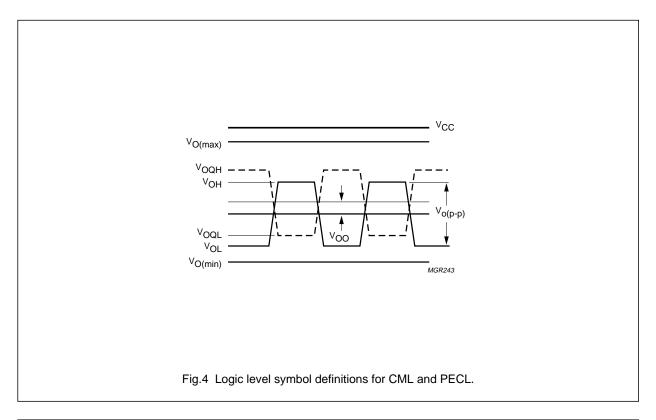

A control loop connected between the limiting amplifier output and the differential amplifier input cancels the DC offset. The loop bandwidth is fixed internally at 30 kHz.

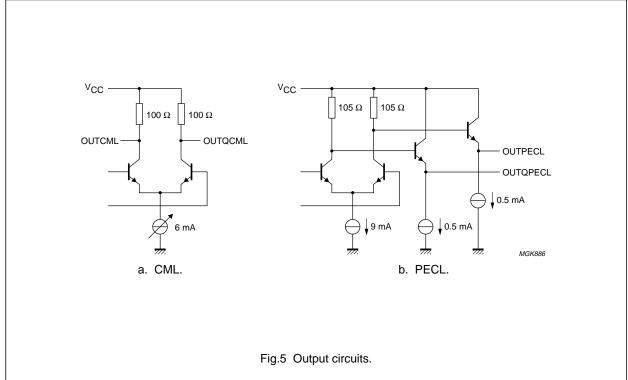

Loss Of Signal (LOS) detection

The LOS section detects an input signal level below a fixed threshold. The threshold is determined by the current through pin LOSTH. If this current is increased, the threshold level will rise. An external resistor connected between pin LOSTH and V_{CCA} can be used, or a current can be forced into pin LOSTH. The default value for the external resistor is 400 k Ω . In this case, the current through pin LOSTH will be approximately 3.75 µA since the voltage at pin LOSTH is regulated at 1.5 V below the supply voltage. This threshold corresponds to an input current of 208 nA. The ratio of LOSTH current to input current is thus approximately 18:1. When the input signal level falls below this threshold, the LOS (PECL compatible) and LOSTTL (TTL compatible) outputs go HIGH. The hysteresis is fixed internally at 3 dB. Response time is typically less than 20 µs.

Notes

- 1. OUTPECL, OUTQPECL, OUTCML, OUTQCML, LOS and LOSQ outputs are left unconnected. OUTPECL and OUTQPECL outputs are active.
- 2. OUTPECL and OUTQPECL outputs are terminated with 50 Ω to V_T. V_T is an external termination voltage for PECL outputs and is 2 V below the supply voltage. OUTCML, OUTQCML, LOS and LOSQ outputs are left unconnected.
- 3. OUTCML and OUTQCML outputs are terminated with 50 Ω to V_{CCD}; CML outputs are active. OUTPECL, OUTQPECL, LOS and LOSQ outputs are left unconnected.
- 4. The bandwidth is set to 120 MHz by default. It can be varied between 90 and 150 MHz by adjusting the voltage at pin BWC.
- 5. All $I_{n(tot)}$ measurements were made with an input capacitance of $C_i = 1.2$ pF. This was comprised of 0.7 pF for the photodiode itself, with 0.3 pF allowed for the PCB layout and 0.2 pF intrinsic to the package.
- 6. PSRR is defined as the ratio of the equivalent current change at the input (ΔI_{IPhoto}) to a change in supply voltage:

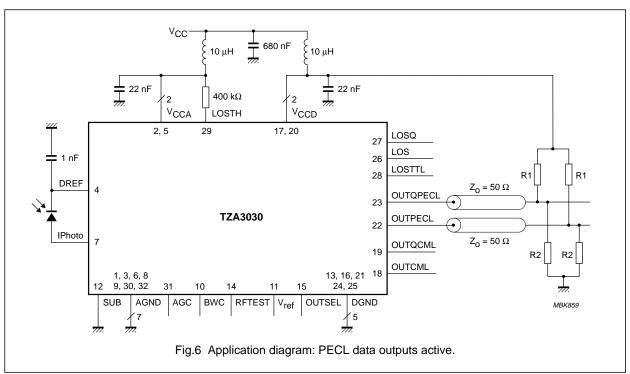

$$PSRR = \frac{\Delta I_{IPhoto}}{\Delta V_{CC}}$$

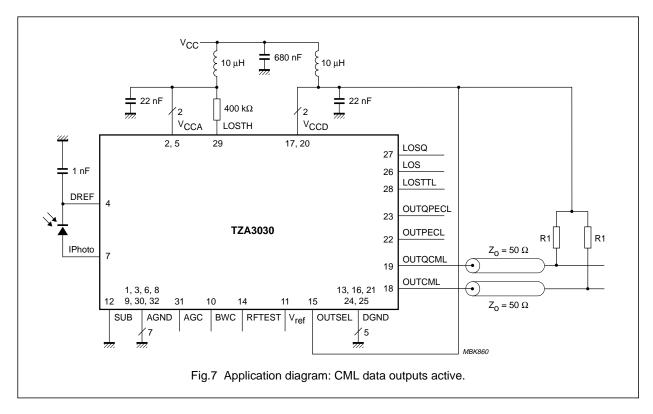

For example, a 4 mV disturbance on V_{CC}at 10 MHz will typically generate the equivalent of 2 nA extra photodiode current.

SDH/SONET STM1/OC3 optical receiver

TZA3030

CML outputs: OUTCML and OUTQCML

The output impedance of the CML output driver is 100 Ω (see Fig.9) which doesn't match the characteristic impedance of the strip line. While this means that the reflections of some incident edges will arrive at the driver output on the PCB, this value was selected to reduce power dissipation inside the IC. The parallel combination of 100 Ω and 50 Ω (33 Ω) will generate a signal swing of 200 mV (peak-to-peak value, single-sided) with a tail current of 6 mA.

If the output impedance was 50 Ω rather than 100 Ω , an 8 mA tail current would be needed to generate the same voltage swing. This would increase power dissipation by 33%.

If necessary, the output impedance of the generator can be matched to the line impedance by connecting an external 100 Ω resistor in parallel with the output as shown in Fig.10. The magnitude of the output voltage swing will not change due to adaptive regulation. However, power dissipation will increase by 33%.

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our "Data Handbook IC26; Integrated Circuit Packages" (order code 9398 652 90011).

Reflow soldering

Reflow soldering techniques are suitable for all LQFP packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several methods exist for reflowing; for example, infrared/convection heating in a conveyor type oven. Throughput times (preheating, soldering and cooling) vary between 50 and 300 seconds depending on heating method. Typical reflow peak temperatures range from 215 to 250 °C.

Wave soldering

Wave soldering is **not** recommended for LQFP packages. This is because of the likelihood of solder bridging due to closely-spaced leads and the possibility of incomplete solder penetration in multi-lead devices.

CAUTION

Wave soldering is NOT applicable for all LQFP packages with a pitch (e) equal or less than 0.5 mm.

If wave soldering cannot be avoided, for LQFP packages with a pitch (e) larger than 0.5 mm, the following conditions must be observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The footprint must be at an angle of 45° to the board direction and must incorporate solder thieves downstream and at the side corners.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Repairing soldered joints

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

DEFINITIONS

| Data sheet status | | | | |
|---------------------------|---|--|--|--|
| Objective specification | This data sheet contains target or goal specifications for product development. | | | |
| Preliminary specification | This data sheet contains preliminary data; supplementary data may be published later. | | | |
| Product specification | This data sheet contains final product specifications. | | | |
| Limiting values | | | | |

Limiting values

Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

Application information

Where application information is given, it is advisory and does not form part of the specification.

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
