

8/16-bit Microcontroller with Serial Communication Interfaces

1. Description

The TSC80251G2D products are derivatives of the TEMIC Microcontroller family based on the 8/16-bit C251 Architecture. This family of products is tailored to 8/16-bit microcontroller applications requiring an increased instruction throughput, a reduced operating frequency or a larger addressable memory space. The architecture can provide a significant code size reduction when compiling C programs while fully preserving the legacy of C51 assembly routines.

The TSC80251G2D derivatives are pin and software compatible with standard 80C51/Fx/Rx/Rx+ with extended on-chip data memory (1 Kbyte RAM) and up to 256 Kbytes of external code and data. Additionally,

the TSC83251G2D and TSC87251G2D provide on-chip code memory: 32 Kbytes ROM and 32 Kbytes EPROM/OTPROM respectively.

They provide transparent enhancements to Intel's 8xC251Sx family with an additional Synchronous Serial Link Controller (SSLC supporting I²C, μ Wire and SPI protocols), a Keyboard interrupt interface, a dedicated Baud Rate Generator for UART, and Power Management features.

TSC80251G2D derivatives are optimized for speed and for low power consumption on a wide voltage range.

Note:

This Datasheet provides the technical description of the TSC80251G2D derivatives. For further information on the device usage, please request the TSC80251 Programmer's Guide and the TSC80251G1D Design Guide.

2. Typical Applications

- ISDN Terminals
- High-Speed Modems
- PABX (SOHO)
- Line Cards
- DVD ROM and Players
- Printers
- Plotters
- Scanners
- Banking Machines
- Barcode Readers
- Smart Cards Readers
- High-End Digital Monitors
- High-End Joysticks

3. Features

- Pin and Software Compatibility with Standard 80C51 Products and 80C51Fx/Rx/Rx+
- Plug-In Replacement of Intel's 8xC251Sx
- C251 core: Intel's MCS[®]251 D-step Compliance
 - 40-byte register file
 - Registers accessible as Bytes, Words or Dwords
 - Three-stage instruction pipeline
 - 16-bit internal code fetch
- Enriched C51 Instruction Set
 - 16-bit and 32-bit ALU
 - Compare and conditional jump instructions
 - Expanded set of move instructions
- Linear Addressing
- 1 Kbyte of On-Chip RAM
- External Memory Space (Code/Data) Programmable from 64 Kbytes to 256 Kbytes
- TSC87251G2D: 32 Kbytes of On-Chip EPROM/OTPROM
 - SINGLE PULSE Programming Algorithm
- TSC83251G2D: 32 Kbytes of On-Chip Masked ROM
- TSC80251G2D: ROMless Version
- Four 8-bit Parallel I/O Ports (Ports 0, 1, 2 and 3 of the standard 80C51)
- Serial I/O Port: full duplex UART (80C51 compatible) with independent Baud Rate Generator
- SSLC: Synchronous Serial Link Controller
 - I²C multi-master protocol
 - μ Wire and SPI master and slave protocols
- Three 16-bit Timers/Counters (Timers 0, 1 and 2 of the standard 80C51)
- EWC: Event and Waveform Controller
 - Compatible with Intel's Programmable Counter Array (PCA)
 - Common 16-bit timer/counter reference with four possible clock sources ($F_{osc}/4$, $F_{osc}/12$, Timer 1 and external input)
 - Five modules, each with four programmable modes:
 - 16-bit software timer/counter
 - 16-bit timer/counter capture input and software pulse measurement
 - High-speed output and 16-bit software pulse width modulation (PWM)
 - 8-bit hardware PWM without overhead
 - 16-bit watchdog timer/counter capability
- Secure 14-bit Hardware Watchdog Timer
- Power Management
 - Power-On reset (integrated on the chip)
 - Power-Off flag (cold and warm resets)
 - Software programmable system clock
 - Idle mode
 - Power-Down mode
- Keyboard Interrupt Interface on Port 1
- Non Maskable Interrupt Input (NMI)
- Real-Time Wait States Inputs (WAIT#/AWAIT#)
- ONCE mode and full speed Real-Time In-Circuit Emulation support (Third Party Vendors)
- High Speed Versions:
 - 4.5 to 5.5 V
 - 16 MHz and 24 MHz
 - Typical operating current: 35 mA @ 24 MHz
24 mA @ 16 MHz
 - Typical power-down current: 2 μ A
- Low Voltage Version:
 - 2.7 to 5.5 V
 - 16 MHz
 - Typical operating current: 11 mA @ 3V
 - Typical power-down current: 1 μ A
- Temperature Ranges:
 - Commercial (0°C to +70°C)
 - Industrial (-40°C to +85°C)
 - Option: extended range (-55°C to +125°C)
- Packages:
 - PDIL 40, PLCC 44 and VQFP 44
 - CDIL 40 and CQPJ 44 with window
 - Options: known good dice and ceramic packages

5.2 Signals

Table 2. Product Name Signal Descriptions

Signal Name	Type	Description	Alternate Function
A17	O	18th Address Bit Output to memory as 18th external address bit (A17) in extended bus applications, depending on the values of bits RD0 and RD1 in UCONFIG0 byte (see Table 13, Page 15).	P1.7
A16	O	17th Address Bit Output to memory as 17th external address bit (A16) in extended bus applications, depending on the values of bits RD0 and RD1 in UCONFIG0 byte (see Table 13, Page 15).	P3.7
A15:8 ⁽¹⁾	O	Address Lines Upper address lines for the external bus.	P2.7:0
AD7:0 ⁽¹⁾	I/O	Address/Data Lines Multiplexed lower address lines and data for the external memory.	P0.7:0
ALE	O	Address Latch Enable ALE signals the start of an external bus cycle and indicates that valid address information are available on lines A16/A17 and A7:0. An external latch can use ALE to demultiplex the address from address/data bus.	
AWAIT#	I	Real-time Asynchronous Wait States Input When this pin is active (low level), the memory cycle is stretched until it becomes high. When using the Product Name as a pin-for-pin replacement for a 8xC51 product, AWAIT# can be unconnected without loss of compatibility or power consumption increase (on-chip pull-up). Not available on DIP package.	
CEX4:0	I/O	PCA Input/Output pins CEXx are input signals for the PCA capture mode and output signals for the PCA compare and PWM modes.	P1.7:3
EA#	I	External Access Enable EA# directs program memory accesses to on-chip or off-chip code memory. For EA#= 0, all program memory accesses are off-chip. For EA#= 1, an access is on-chip ROM if the address is within the range of the on-chip ROM; otherwise the access is off-chip. The value of EA# is latched at reset. For devices without ROM on-chip, EA# must be strapped to ground.	
ECI	O	PCA External Clock input ECI is the external clock input to the 16-bit PCA timer.	P1.2
MISO	I/O	SPI Master Input Slave Output line When SPI is in master mode, MISO receives data from the slave peripheral. When SPI is in slave mode, MISO outputs data to the master controller.	P1.5
MOSI	I/O	SPI Master Output Slave Input line When SPI is in master mode, MOSI outputs data to the slave peripheral. When SPI is in slave mode, MOSI receives data from the master controller.	P1.7
INT1:0#	I	External Interrupts 0 and 1 INT1#/INT0# inputs set IE1:0 in the TCON register. If bits IT1:0 in the TCON register are set, bits IE1:0 are set by a falling edge on INT1#/INT0#. If bits IT1:0 are cleared, bits IE1:0 are set by a low level on INT1#/INT0#.	P3.3:2
NMI	I	Non Maskable Interrupt Holding this pin high for 24 oscillator periods triggers an interrupt. When using the Product Name as a pin-for-pin replacement for a 8xC51 product, NMI can be unconnected without loss of compatibility or power consumption increase (on-chip pull-down). Not available on DIP package.	
P0.0:7	I/O	Port 0 P0 is an 8-bit open-drain bidirectional I/O port. Port 0 pins that have 1s written to them float and can be used as high impedance inputs. To avoid any parasitic current consumption, Floating P0 inputs must be polarized to V _{DD} or V _{SS} .	AD7:0

Signal Name	Type	Description	Alternate Function
P1.0:7	I/O	Port 1 P1 is an 8-bit bidirectional I/O port with internal pull-ups. P1 provides interrupt capability for a keyboard interface.	
P2.0:7	I/O	Port 2 P2 is an 8-bit bidirectional I/O port with internal pull-ups.	A15:8
P3.0:7	I/O	Port 3 P3 is an 8-bit bidirectional I/O port with internal pull-ups.	
PROG#	I	Programming Pulse input The programming pulse is applied to this input for programming the on-chip EPROM/OTEPROM.	
PSEN#	O	Program Store Enable/Read signal output PSEN# is asserted for a memory address range that depends on bits RD0 and RD1 in UCONFIG0 byte (see Table 13, Page 15).	
RD#	O	Read or 17th Address Bit (A16) Read signal output to external data memory depending on the values of bits RD0 and RD1 in UCONFIG0 byte (see Table 13, Page 15).	P3.7
RST	I	Reset input to the chip Holding this pin high for 64 oscillator periods while the oscillator is running resets the device. The Port pins are driven to their reset conditions when a voltage greater than V_{IH1} is applied, whether or not the oscillator is running. This pin has an internal pull-down resistor which allows the device to be reset by connecting a capacitor between this pin and VDD. Asserting RST when the chip is in Idle mode or Power-Down mode returns the chip to normal operation.	
RXD	I/O	Receive Serial Data RXD sends and receives data in serial I/O mode 0 and receives data in serial I/O modes 1, 2 and 3.	P3.0
SCL	I/O	I²C Serial Clock When I ² C controller is in master mode, SCL outputs the serial clock to slave peripherals. When I ² C controller is in slave mode, SCL receives clock from the master controller.	P1.6
SCK	I/O	SPI Serial Clock When SPI is in master mode, SCK outputs clock to the slave peripheral. When SPI is in slave mode, SCK receives clock from the master controller.	P1.6
SDA	I/O	I²C Serial Data SDA is the bidirectional I ² C data line.	P1.7
SS#	I	SPI Slave Select Input When in Slave mode, SS# enables the slave mode.	P1.4
T1:0	I/O	Timer 1:0 External Clock Inputs When timer 1:0 operates as a counter, a falling edge on the T1:0 pin increments the count.	
T2	I/O	Timer 2 Clock Input/Output For the timer 2 capture mode, T2 is the external clock input. For the Timer 2 clock-out mode, T2 is the clock output.	P1.0
T2EX	I	Timer 2 External Input In timer 2 capture mode, a falling edge initiates a capture of the timer 2 registers. In auto-reload mode, a falling edge causes the timer 2 register to be reloaded. In the up-down counter mode, this signal determines the count direction: 1= up, 0= down.	P1.1
TXD	O	Transmit Serial Data TXD outputs the shift clock in serial I/O mode 0 and transmits data in serial I/O modes 1, 2 and 3.	P3.1
VDD	PWR	Digital Supply Voltage Connect this pin to +5V or +3V supply voltage.	
VPP	I	Programming Supply Voltage The programming supply voltage is applied to this input for programming the on-chip EPROM/OTEPROM.	

Signal Name	Type	Description	Alternate Function
VSS	GND	Circuit Ground Connect this pin to ground.	
VSS1	GND	Secondary Ground 1 This ground is provided to reduce ground bounce and improve power supply bypassing. Connection of this pin to ground is recommended. However, when using the TSC80251G2D as a pin-for-pin replacement for a 8xC51 product, VSS1 can be unconnected without loss of compatibility. Not available on DIP package.	
VSS2	GND	Secondary Ground 2 This ground is provided to reduce ground bounce and improve power supply bypassing. Connection of this pin to ground is recommended. However, when using the TSC80251G2D as a pin-for-pin replacement for a 8xC51 product, VSS2 can be unconnected without loss of compatibility. Not available on DIP package.	
WAIT#	I	Real-time Synchronous Wait States Input The real-time WAIT# input is enabled by setting RTWE bit in WCON (S:A7h). During bus cycles, the external memory system can signal 'system ready' to the microcontroller in real time by controlling the WAIT# input signal.	P1.6
WCLK	O	Wait Clock Output The real-time WCLK output is enabled by setting RTWCE bit in WCON (S:A7h). When enabled, the WCLK output produces a square wave signal with a period of one half the oscillator frequency.	P1.7
WR#	O	Write Write signal output to external memory.	P3.6
XTAL1	I	Input to the on-chip inverting oscillator amplifier To use the internal oscillator, a crystal/resonator circuit is connected to this pin. If an external oscillator is used, its output is connected to this pin. XTAL1 is the clock source for internal timing.	
XTAL2	O	Output of the on-chip inverting oscillator amplifier To use the internal oscillator, a crystal/resonator circuit is connected to this pin. If an external oscillator is used, leave XTAL2 unconnected.	

Note:

1. The description of A15:8/P2.7:0 and AD7:0/P0.7:0 are for the Non-Page mode chip configuration. If the chip is configured in Page mode operation, port 0 carries the lower address bits (A7:0) while port 2 carries the upper address bits (A15:8) and the data (D7:0).

6. Address Spaces

The TSC80251G2D derivatives implement four different address spaces:

- On-chip ROM program/code memory (not present in ROMless devices)
- On-chip RAM data memory
- Special Function Registers (SFRs)
- Configuration array

6.1 Program/Code Memory

The TSC83251G2D and TSC87251G2D implement 32 Kbytes of on-chip program/code memory. Figure 5 shows the split of the internal and external program/code memory spaces. If EA# is tied to a high level, the 32-Kbyte on-chip program memory is mapped in the lower part of segment FF: where the C251 core jumps after reset. The rest of the program/code memory space is mapped to the external memory. If EA# is tied to a low level, the internal program/code memory is not used and all the accesses are directed to the external memory.

The TSC83251G2D products provide the internal program/code memory in a masked ROM memory while the TSC87251G2D products provide it in an EPROM memory. For the TSC80251G2D products, there is no internal program/code memory and EA# must be tied to a low level.

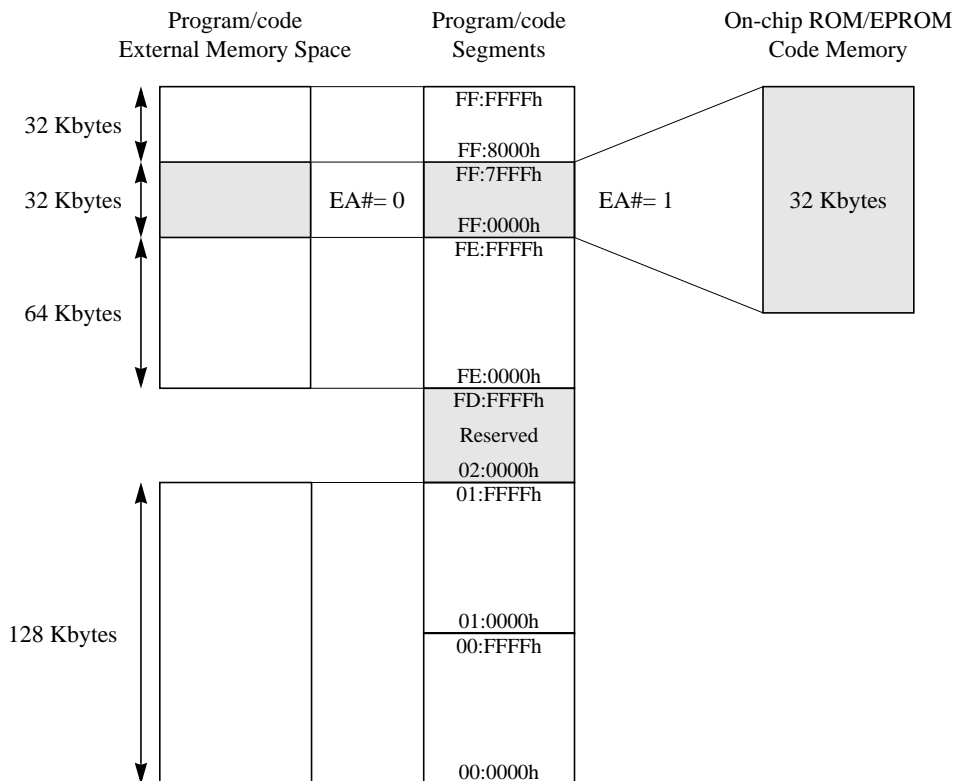

Figure 5. Program/Code Memory Mapping

Notes:

Special care should be taken when the Program Counter (PC) increments:

1. If the program executes exclusively from on-chip code memory (not from external memory), beware of executing code from the upper eight bytes of the on-chip ROM (FF:7FF8h-FF:7FFFh). Because of its pipeline capability, the TSC80251G2D derivative may attempt to prefetch code from external memory (at an address above FF:7FFFh) and thereby disrupt I/O Ports 0 and 2. Fetching code constants from these 8 bytes does not affect Ports 0 and 2.
2. When PC reaches the end of segment FF:, it loops to the reset address FF:0000h (for compatibility with the C51 Architecture). When PC increments beyond the end of segment FE:, it continues at the reset address FF:0000h (linearity). When PC increments beyond the end of segment 01:, it loops to the beginning of segment 00: (this prevents from its going into the reserved area).

6.2 Data Memory

The TSC80251G2D derivatives implement 1 Kbyte of on-chip data RAM. Figure 6 shows the split of the internal and external data memory spaces. This memory is mapped in the data space just over the 32 bytes of registers area (see TSC80251 Programmers' Guide). Hence, the part of the on-chip RAM located from 20h to FFh is bit addressable. This on-chip RAM is not accessible through the program/code memory space.

For faster computation with the on-chip ROM/EPROM code of the TSC83251G2D/TSC87251G2D, its upper 16 Kbytes are also mapped in the upper part of the region 00: if the On-Chip Code Memory Map configuration bit is cleared (EMAP# bit in UCONFIG1 byte, see Figure 8). However, if EA# is tied to a low level, the TSC80251G2D derivative is running as a ROMless product and the code is actually fetched in the corresponding external memory (i.e. the upper 16 Kbytes of the lower 32 Kbytes of the segment FF:). If EMAP# bit is set, the on-chip ROM is not accessible through the region 00:.

All the accesses to the portion of the data space with no on-chip memory mapped onto are redirected to the external memory.

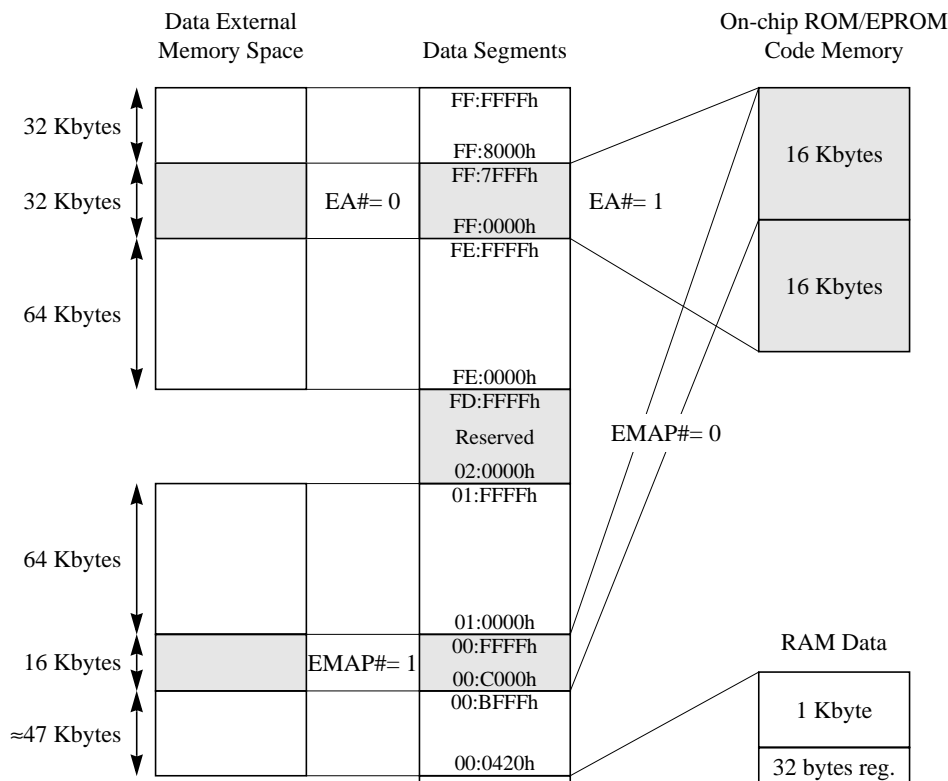

Figure 6. Data Memory Mapping

6.3 Special Function Registers

The Special Function Registers (SFRs) of the TSC80251G2D derivatives fall into the categories detailed in Table 3 to Table 11.

SFRs are placed in a reserved on-chip memory region S: which is not represented in the data memory mapping (Figure 6). The relative addresses within S: of these SFRs are provided together with their reset values in Table 12. They are upward compatible with the SFRs of the standard 80C51 and the Intel's 80C251Sx family. In this table, the C251 core registers are identified by Note 1 and are described in the TSC80251 Programmer's Guide. The other SFRs are described in the TSC80251G1D Design Guide. All the SFRs are bit-addressable using the C251 instruction set.

Notes:

1. These registers are described in the TSC80251 Programmer's Guide (C251 core registers).
2. In I²C and SPI modes, SSSCON is splitted in two separate registers. SSSCON reset value is 0000 0000 in I²C mode and 0000 0100 in SPI mode.
3. In read and write modes, SSSCS is splitted in two separate registers. SSSCS reset value is 1111 1000 in read mode and 0000 0000 in write mode.

6.4 Configuration Bytes

The TSC80251G2D derivatives provide user design flexibility by configuring certain operating features at device reset. These features fall into the following categories:

- external memory interface (Page mode, address bits, programmed wait states and the address range for RD#, WR#, and PSEN#)
- source mode/binary mode opcodes
- selection of bytes stored on the stack by an interrupt
- mapping of the upper portion of on-chip code memory to region 00:

Two user configuration bytes UCONFIG0 (see Figure 7) and UCONFIG1 (see Figure 8) provide the information.

When EA# is tied to a low level, the configuration bytes are fetched from the external address space. The TSC80251G2D derivatives reserve the top eight bytes of the memory address space (FF:FFF8h-FF:FFFh) for an external 8-byte configuration array. Only two bytes are actually used: UCONFIG0 at FF:FFF8h and UCONFIG1 at FF:FFF9h.

For the mask ROM devices, configuration information is stored in on-chip memory (see ROM Verifying). When EA# is tied to a high level, the configuration information is retrieved from the on-chip memory instead of the external address space and there is no restriction in the usage of the external memory.

3	RD1	Memory Signal Select bits Specify a 18-bit, 17-bit or 16-bit external address bus and the usage of RD#, WR# and PSEN# signals (see Table 13).															
2	RD0																
1	PAGE#	Page Mode Select bit⁽¹⁾ Clear to select the faster Page mode with A15:8/D7:0 on Port 2 and A7:0 on Port 0. Set to select the non-Page mode ⁽²⁾ with A15:8 on Port 2 and A7:0/D7:0 on Port 0.															
0	SRC	Source Mode/Binary Mode Select bit Clear to select the binary mode. Set to select the source mode.															

Notes:

1. UCONFIG0 is fetched twice so it can be properly read both in Page or Non-Page modes. If P2.1 is cleared during the first data fetch, a Page mode configuration is used, otherwise the subsequent fetches are performed in Non-Page mode.
2. This selection provides compatibility with the standard 80C51 hardware which is multiplexing the address LSB and the data on Port 0.

Note:

1. This selection provides compatibility with the standard 80C51 hardware which has separate external memory spaces for data and code.

7. Instruction Set Summary

This section contains tables that summarize the instruction set. For each instruction there is a short description, its length in bytes, and its execution time in states (one state time is equal to two system clock cycles). There are two concurrent processes limiting the effective instruction throughput:

- Instruction Fetch
- Instruction Execution

Table 20 to Table 34 assume code executing from on-chip memory, then the CPU is fetching 16-bit at a time and this is never limiting the execution speed.

If the code is fetched from external memory, a pre-fetch queue will store instructions ahead of execution to optimize the memory bandwidth usage when slower instructions are executed. However, the effective speed may be limited depending on the average size of instructions (for the considered section of the program flow). The maximum average instruction throughput is provided by Table 14 depending on the external memory configuration (from Page Mode to Non-Page Mode and the maximum number of wait states). If the average size of instructions is not an integer, the maximum effective throughput is found by pondering the number of states for the neighbor integer values.

Table 14. Minimum Number of States per Instruction for given Average Sizes

Average size of Instructions (bytes)	Page Mode (states)	Non-Page Mode (states)				
		0 Wait State	1 Wait State	2 Wait States	3 Wait States	4 Wait States
1	1	2	3	4	5	6
2	2	4	6	8	10	12
3	3	6	9	12	15	18
4	4	8	12	16	20	24
5	5	10	15	20	25	30

If the average execution time of the considered instructions is larger than the number of states given by Table 14, this larger value will prevail as the limiting factor. Otherwise, the value from Table 14 must be taken. This is providing a fair estimation of the execution speed but only the actual code execution can provide the final value.

7.1 Notation for Instruction Operands

Table 15 to Table 19 provide notation for Instruction Operands.

Table 15. Notation for Direct Addressing

Direct Address	Description	C251	C51
dir8	A direct 8-bit address. This can be a memory address (00h-7Fh) or a SFR address (80h-FFh). It is a byte (default), word or double word depending on the other operand.	✓	✓
dir16	A 16-bit memory address (00:0000h-00:FFFFh) used in direct addressing.	✓	

Table 16. Notation for Immediate Addressing

Immediate Address	Description	C251	C51
#data	An 8-bit constant that is immediately addressed in an instruction	✓	✓
#data16	A 16-bit constant that is immediately addressed in an instruction	✓	
#0data16 #1data16	A 32-bit constant that is immediately addressed in an instruction. The upper word is filled with zeros (#0data16) or ones (#1data16).	✓	
#short	A constant, equal to 1, 2, or 4, that is immediately addressed in an instruction.	✓	

Table 17. Notation for Bit Addressing

Direct Address	Description	C251	C51
bit51	A directly addressed bit (bit number= 00h-FFh) in memory or an SFR. Bits 00h-7Fh are the 128 bits in byte locations 20h-2Fh in the on-chip RAM. Bits 80h-FFh are the 128 bits in the 16 SFRs with addresses that end in 0h or 8h, S:80h, S:88h, S:90h, ..., S:F0h, S:F8h.		✓
bit	A directly addressed bit in memory locations 00:0020h-00:007Fh or in any defined SFR.	✓	

Table 18. Notation for Destination in Control Instructions

Direct Address	Description	C251	C51
rel	A signed (two's complement) 8-bit relative address. The destination is -128 to +127 bytes relative to the next instruction's first byte.	✓	✓
addr11	An 11-bit target address. The target is in the same 2-Kbyte block of memory as the next instruction's first byte.		✓
addr16	A 16-bit target address. The target can be anywhere within the same 64-Kbyte region as the next instruction's first byte.		✓
addr24	A 24-bit target address. The target can be anywhere within the 16-Mbyte address space.	✓	

Table 19. Notation for Register Operands

Register	Description	C251	C51
@Ri	A memory location (00h-FFh) addressed indirectly via byte registers R0 or R1		✓
Rn n	Byte register R0-R7 of the currently selected register bank Byte register index: n= 0-7		✓
Rm Rmd Rms m, md, ms	Byte register R0-R15 of the currently selected register file Destination register Source register Byte register index: m, md, ms= 0-15	✓	
WRj WRjd WRjs @WRj @WRj +dis16 j, jd, js	Word register WR0, WR2, ..., WR30 of the currently selected register file Destination register Source register A memory location (00:0000h-00:FFFFh) addressed indirectly through word register WR0-WR30, is the target address for jump instructions. A memory location (00:0000h-00:FFFFh) addressed indirectly through word register (WR0-WR30) + 16-bit signed (two's complement) displacement value Word register index: j, jd, js= 0-30	✓	
DRk DRkd DRks @DRk @DRk +dis16 k, kd, ks	Dword register DR0, DR4, ..., DR28, DR56, DR60 of the currently selected register file Destination register Source register A memory location (00:0000h-FF:FFFFh) addressed indirectly through dword register DR0-DR28, DR56 and DR60, is the target address for jump instruction A memory location (00:0000h-FF:FFFFh) addressed indirectly through dword register (DR0-DR28, DR56, DR60) + 16-bit (two's complement) signed displacement value Dword register index: k, kd, ks= 0, 4, 8, ..., 28, 56, 60	✓

Notes:

1. A shaded cell denotes an instruction in the C51 Architecture.
2. Extended memory addressed is in the region specified by DPXL (reset value= 01h).
3. If this instruction addresses external memory location, add N+1 to the number of states (N: number of wait states).
4. If this instruction addresses external memory location, add N+2 to the number of states (N: number of wait states).

8. Programming and Verifying Non-Volatile Memory

8.1 Internal Features

The internal non-volatile memory of the TSC80251G2D derivatives contains five different areas:

- Code Memory
- Configuration Bytes
- Lock Bits
- Encryption Array
- Signature Bytes

8.1.1 EPROM/OTPROM Devices

All the internal non-volatile memory but the Signature Bytes of the TSC87251G2D products is made of EPROM cells. The Signature Bytes of the TSC87251G2D products are made of Mask ROM.

The TSC87251G2D products are programmed and verified in the same manner as TEMIC's TSC87251G1A, using a SINGLE-PULSE algorithm, which programs at $V_{pp}=12.75V$ using only one 100 μs pulse per byte. This results in a programming time of less than 10 seconds for the 32 Kbytes on-chip code memory.

The EPROM of the TSC87251G2D products in Window package is erasable by Ultra-Violet radiation⁽¹⁾ (UV). UV erasure set all the EPROM memory cells to one and allows a reprogramming. The quartz window must be covered with an opaque label⁽²⁾ when the device is in operation. This is not so much to protect the EPROM array from inadvertent erasure, as to protect the RAM and other on-chip logic. Allowing light to impinge on the silicon die during device operation may cause a logical malfunction.

The TSC87251G2D products in plastic packages are One Time Programmable (OTP). Then an EPROM cell cannot be reset by UV once programmed to zero.

Notes:

1. The recommended erasure procedure is exposure to ultra-violet light (at 2537 Å) to an integrated dose of at least 20 W-sec/cm². Exposing the EPROM to an ultra-violet lamp of 12000 $\mu W/cm^2$ rating for 30 minutes should be sufficient.
2. Erasure of the EPROM begins to occur when the chip is exposed to light wavelength shorter than 4000 Å. Since sunlight and fluorescent light have wavelength in this range, exposure to these light sources over an extended time (1 week in sunlight or 3 years in room-level fluorescent lighting) could cause inadvertent erasure.

8.1.2 Mask ROM Devices

All the internal non-volatile memory of TSC83251G2D products is made of Mask ROM cells. They can only be verified by the user, using the same algorithm as the EPROM/OTPROM devices.

8.1.3 ROMless Devices

The TSC80251G2D products do not include on-chip Configuration Bytes, Code Memory and Encryption Array. They only include Signature Bytes made of Mask ROM cells which can be read using the same algorithm as the EPROM/OTPROM devices.

8.2 Security Features

In some microcontrollers applications, it is desirable that the user's program code be secured from unauthorized access. The TSC83251G2D and TSC87251G2D offer two kinds of protection for program code stored in the on-chip array:

- Program code in the on-chip Code Memory is encrypted when read out for verification if the Encryption Array is programmed.
- A three-level lock bit system restricts external access to the on-chip code memory.

8.2.1 Lock Bit System

The TSC87251G2D products implement 3 levels of security for User's program as described in Table 35. The TSC83251G2D products implement only the first level of security.

Level 0 is the level of an erased part and does not enable any security features.

Level 1 locks the programming of the User's internal Code Memory, the Configuration Bytes and the Encryption Array.

Level 2 locks the verifying of the User's internal Code Memory. It is always possible to verify the Configuration Bytes and the Lock Bits. It is never possible to verify the Encryption Array.

Level 3 locks the external execution.

1. Returns encrypted data if Encryption Array is programmed.
2. Returns non encrypted data.
3. x means don't care. Level 2 always enables level 1, and level 3 always enables levels 1 and 2.

The security level may be verified according to Table 36.

Table 36. Lock Bits Verifying

Note:

1. x means don't care.

8.2.2 Encryption Array

The TSC83251G2D and TSC87251G2D products include a 128-byte Encryption Array located in non-volatile memory outside the memory address space. During verification of the on-chip code memory, the seven low-order address bits also address the Encryption Array. As the byte of the code memory is read, it is exclusive-NOR'ed (XNOR) with the key byte from the Encryption Array. If the Encryption Array is not programmed (still all 1s), the user program code is placed on the data bus in its original, unencrypted form. If the Encryption Array is programmed with key bytes, the user program code is encrypted and cannot be used without knowledge of the key byte sequence.

To preserve the secrecy of the encryption key byte sequence, the Encryption Array can not be verified.

Cautions:

1. When a MOVC instruction is executed, the content of the ROM is not encrypted. In order to fully protect the user program code, the lock bit level 1 (see Table 35) must always be set when encryption is used.
2. If the encryption feature is implemented, the portion of the on-chip code memory that does not contain program code should be filled with "random" byte values to prevent the encryption key sequence from being revealed.

8.3 Signature Bytes

The TSC80251G2D derivatives contain factory-programmed Signature Bytes. These bytes are located in non-volatile memory outside the memory address space at 30h, 31h, 60h and 61h. To read the Signature Bytes, perform the procedure described in section 8.5, using the verify signature mode (see Table 39). Signature byte values are listed in Table 37.

Table 37. Signature Bytes (Electronic ID)

8.4 Programming Algorithm

Figure 9 shows the hardware setup needed to program the TSC87251G2D EPROM/OTPROM areas:

- The chip has to be put under reset and maintained in this state until the completion of the programming sequence.
- PSEN# and the other control signals (ALE and Port 0) have to be set to a high level.
- Then PSEN# has to be forced to a low level after two clock cycles or more and it has to be maintained in this state until the completion of the programming sequence (see below).
- The voltage on the EA# pin must be set to V_{DD} .
- The programming mode is selected according to the code applied on Port 0 (see Table 38). It has to be applied until the completion of this programming operation.
- The programming address is applied on Ports 1 and 3 which are respectively the Most Significant Byte (MSB) and the Least Significant Byte (LSB) of the address.
- The programming data are applied on Port 2.
- The EPROM Programming is done by raising the voltage on the EA# pin to V_{PP} , then by generating a low level pulse on ALE/PROG# pin.
- The voltage on the EA# pin must be lowered to V_{DD} before completing the programming operation.
- It is possible to alternate programming and verifying operation (See Paragraph 8.5). Please make sure the voltage on the EA# pin has actually been lowered to V_{DD} before performing the verifying operation.
- PSEN# and the other control signals have to be released to complete a sequence of programming operations or a sequence of programming and verifying operations.

8.5 Verify Algorithm

Figure 10 shows the hardware setup needed to verify the TSC87251G2D EPROM/OTPROM or TSC83251G2D ROM areas:

- The chip has to be put under reset and maintained in this state until the completion of the verifying sequence.
- PSEN# and the other control signals (ALE and Port 0) have to be set to a high level.
- Then PSEN# has to be forced to a low level after two clock cycles or more and it has to be maintained in this state until the completion of the verifying sequence (see below).
- The voltage on the EA# pin must be set to V_{DD} and ALE must be set to a high level.
- The Verifying Mode is selected according to the code applied on Port 0. It has to be applied until the completion of this verifying operation.
- The verifying address is applied on Ports 1 and 3 which are respectively the MSB and the LSB of the address.
- Then device is driving the data on Port 2.
- It is possible to alternate programming and verification operation (see Paragraph 8.4). Please make sure the voltage on the EA# pin has actually been lowered to V_{DD} before performing the verifying operation.
- PSEN# and the other control signals have to be released to complete a sequence of verifying operations or a sequence of programming and verifying operations.

Notes:

1. Under steady-state (non-transient) conditions, I_{OL} must be externally limited as follows:

Maximum I_{OL} per port pin:.....	10 mA
Maximum I_{OL} per 8-bit port:	
Port 0.....	26 mA
Ports 1-3.....	15 mA
Maximum Total I_{OL} for all:	
Output Pins	71 mA

If I_{OL} exceeds the test conditions, V_{OL} may exceed the related specification. Pins are not guaranteed to sink current greater than the listed test conditions.

2. Capacitive loading on Ports 0 and 2 may cause spurious noise pulses above 0.4 V on the low-level outputs of ALE and Ports 1, 2, and 3. The noise is due to external bus capacitance discharging into the Port 0 and Port 2 pins when these pins change from high to low. In applications where capacitive loading exceeds 100 pF, the noise pulses on these signals may exceed 0.8 V. It may be desirable to qualify ALE or other signals with a Schmitt Trigger or CMOS-level input logic.
3. Capacitive loading on Ports 0 and 2 causes the V_{OH} on ALE and PSEN# to drop below the specification when the address lines are stabilizing.
4. Typical values are obtained using $V_{DD} = 5$ V and $T_A = 25^\circ\text{C}$. They are not tested and there is not guarantee on these values.
5. The input threshold voltage of SCL and SDA meets the I^2C specification, so an input voltage below $0.3 \cdot V_{DD}$ will be recognized as a logic 0 while an input voltage above $0.7 \cdot V_{DD}$ will be recognized as a logic 1.

Note:

1. The clock prescaler is not used: $F_{OSC} = F_{XTAL}$.

Notes:

1. At 100 kbit/s. At other bit-rates this value is inversely proportional to the bit-rate of 100 kbit/s.
2. Determined by the external bus-line capacitance and the external bus-line pull-up resistor, this must be < 1 μs.
3. Spikes on the SDA and SCL lines with a duration of less than 3·TCLCL will be filtered out. Maximum capacitance on bus-lines SDA and SCL= 400 pF.
4. TCLCL= T_{OSC}= one oscillator clock period.

Note:

During AC testing, all inputs are driven at $V_{DD} - 0.5$ V for a logic 1 and 0.45 V for a logic 0.

Timing measurements are made on all outputs at $V_{IH\ min}$ for a logic 1 and $V_{IL\ max}$ for a logic 0.

Figure 34. AC Testing Input/Output Waveforms

Note:

For timing purposes, a port pin is no longer floating when a 100 mV change from load voltage occurs and begins to float when a 100 mV change from the loading V_{OH}/V_{OL} level occurs with $I_{OL}/I_{OH} = \pm 20$ mA.
