

## µP Power Supply Supervisor With Battery Backup Switch

### General Description

The ASM690A / ASM692A / ASM802L / ASM802M / ASM805L offers complete single chip solutions for power supply monitoring and control battery functions in microprocessor systems. Each device implements four functions: Reset control, watchdog monitoring, battery-backup switching and powerfailure monitoring. In addition to microprocessor reset under power-up and power-down conditions, these devices provide battery-backup switching to maintain control in power loss and brown-out situations. Additional monitoring capabilities can provide an early warning of unregulated power supply loss before the voltage regulator drops out. The important features of these four functions are:

- 1.6 second watchdog timer to keep microprocessor responsive
- 4.40V or 4.65V VCC threshold for microprocessor reset at power-up and power-down
- SPDT (Single-pole, Double-throw) PMOS switch connects backup power to RAM if VCC fails
- 1.25V threshold detector for power loss or general purpose voltage monitoring

These features are pin-compatible with the industry standard power-supply supervisors. Short-circuit and thermal protection have also been added. The ASM690A / ASM802L / ASM805L generate a reset pulse when the supply voltage drops below 4.65V and the ASM692A / ASM802M generate a reset below 4.40V. The ASM802L / ASM802M have power-fail accuracy to  $\pm 2\%$ . The ASM805L is the same as the ASM690A except that RESET is provided instead of  $\overline{\text{RESET}}$ .

### Features

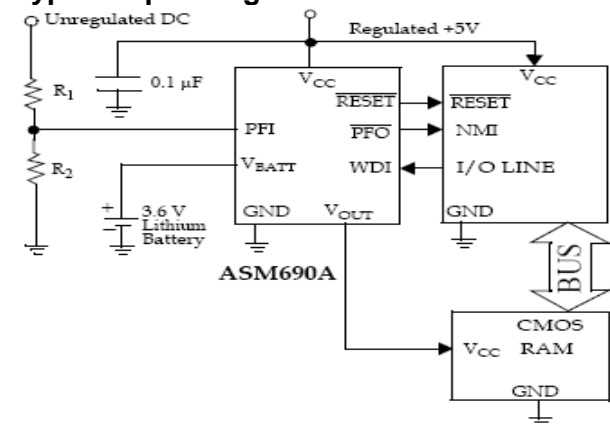

- Two precision supply-voltage monitor options  
4.65V (ASM690A / ASM802L / ASM805L)  
4.40V (ASM692A / ASM802M)
- Battery-backup power switch on-chip
- Watchdog timer: 1.6 second timeout
- Power failure / low battery detection

- Short circuit protection and thermal limiting
- Small 8-pin SO and 8-pin PDIP packages
- No external components
- Specified over full temperature range

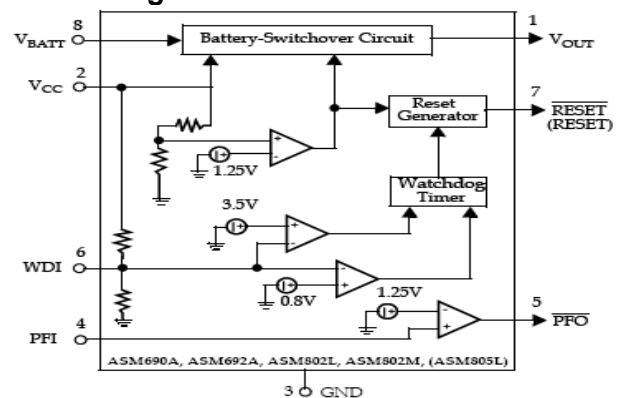

### Applications

- Embedded control systems
- Portable/Battery operated systems
- Intelligent instruments
- Wireless instruments
- Wireless communication systems
- PDAs and hand-held equipments
- µP / µC power supply monitoring
- Safety system

### Typical Operating Circuit

### Block Diagram

## Pin Configuration

## Pin Description

Pin Number		Name	Function
ASM690A/ ASM692A ASM802L/ ASM802M	ASM805L		
1	1	$V_{OUT}$	Voltage supply for RAM. When $V_{CC}$ is above the reset threshold, $V_{OUT}$ connects to $V_{CC}$ through a P-Channel MOS device. If $V_{CC}$ falls below the reset threshold, this output will be connected to the backup supply at $V_{BATT}$ (or $V_{CC}$ , whichever is higher) through the MOS switch to provide continuous power to the CMOS RAM.
2	2	$V_{CC}$	+5V power supply input.
3	3	GND	Ground
4	4	PFI	Power failure monitor input. PFI is connected to the internal power fail comparator which is referenced to 1.25V. The power fail output ( $\overline{PFO}$ ) is active LOW but remains HIGH if PFI is above 1.25V. If this feature is unused, the PFI pin should be connected to GND or $V_{OUT}$ .
5	5	$\overline{PFO}$	Power-fail output. $\overline{PFO}$ is active LOW whenever the PFI pin is less than 1.25V.
6	6	WDI	Watchdog input. The WDI input monitors microprocessor activity. An internal timer is reset with each transition of the WDI input. If the WDI is held HIGH or LOW for longer than the watchdog timeout period, typically 1.6 seconds, $\overline{RESET}$ (or $\overline{RESET}$ ) is asserted for the reset pulse width time, $t_{RS}$ , of 140ms, minimum.
7	-	$\overline{RESET}$	Active-LOW reset output. When triggered by $V_{CC}$ falling below the reset threshold or by watchdog timer timeout, $\overline{RESET}$ pulses low for the reset pulse width $t_{RS}$ , typically 200ms. It will remain low if $V_{CC}$ is below the reset threshold (4.65V in ASM690A / ASM802L and 4.4V in the ASM692A / ASM802L) and remains low for 200ms after $V_{CC}$ rises above the reset threshold.
-	7	RESET	Active-HIGH reset output. The inverse of $\overline{RESET}$ .
8	8	$V_{BATT}$	Auxiliary power or backup-battery input. $V_{BATT}$ should be connected to GND if the function is not used. The input has about 40mV of hysteresis to prevent rapid toggling between $V_{CC}$ and $V_{BATT}$ .

## Detailed Description

It is important to initialize a microprocessor to a known state in response to specific events that could create code execution errors and “lock-up”. The reset output of these supervisory circuits send a reset pulse to the microprocessor in response to power-up, power-down/power-loss or a watchdog time-out.

### RESET/RESET Timing

Power-up reset occurs when a rising  $V_{CC}$  reaches the reset threshold,  $V_{RT}$ , forcing a reset condition in which the reset output is asserted in the appropriate logic state for the duration of  $t_{RS}$ . The reset pulse width,  $t_{RS}$ , is typically around 200ms and is LOW for the ASM690A, ASM692A, ASM802 and HIGH for the ASM805L. *Figure 1* shows the reset pin timing.

Power-loss or “brown-out” reset occurs when  $V_{CC}$  dips below the reset threshold resulting in a reset assertion for the duration of  $t_{RS}$ . The reset signal remains asserted as long as  $V_{CC}$  is between  $V_{RT}$  and 1.1V, the lowest  $V_{CC}$  for which these devices can provide a guaranteed logic-low output. To ensure logic inputs connected to the ASM690A / ASM692A/ASM802 RESET pin are in a known state when  $V_{CC}$  is under 1.1V, a 100kΩ pull-down resistor at RESET is needed: the logic-high ASM805L will need a pull-up resistor to  $V_{CC}$ .

### Watchdog Timer

A Watchdog time-out reset occurs when a logic “1” or logic “0” is continuously applied to the WDI pin for more than 1.6 seconds. After the duration of the reset interval, the watchdog timer starts a new 1.6 second timing interval; the microprocessor must service the watchdog input by changing states or by floating the WDI pin before this interval is finished. If the WDI pin is held either HIGH or LOW, a reset pulse will be triggered every 1.8 seconds (the 1.6 second timing interval plus the reset pulse width  $t_{RS}$ ).

## Application Information

### Microprocessor Interface

The ASM690 has logic-LOW  $\overline{\text{RESET}}$  output while the ASM805 has an inverted logic-HIGH RESET output. Microprocessors with bidirectional reset pins can pose a problem when the supervisory circuit and the microprocessor output pins attempt to go to opposite logic states. The problem can be resolved by placing a 4.7kΩ resistor between the RESET output and the microprocessor reset pin. This is shown in *Figure 2*. Since the series resistor limits drive capabilities, the reset signal to other devices should be buffered.

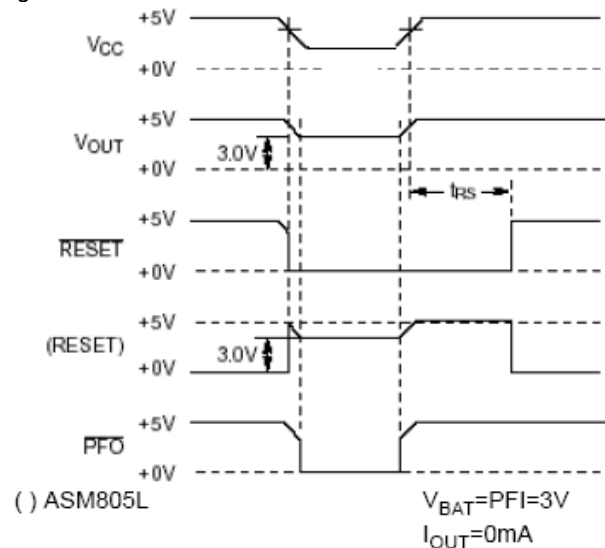

Figure 1: RESET/ $\overline{\text{RESET}}$  Timing

Figure 2: Interfacing with bi-directional microprocessor reset inputs

### Watchdog Input

As discussed in the Reset section, the Watchdog input is used to monitor microprocessor activity. It can be used to insure that the microprocessor is in a continually responsive state by requiring that the WDI pin be toggled every second. If the WDI pin is not toggled within the 1.6 second window (minimum  $t_{WD} + t_{RS}$ ), a reset pulse will be asserted to return the microprocessor to the initial start-up state. Pulses as short as 50ns can be applied to the WDI pin. If this feature is not used, the WDI pin should be open circuited or the logic placed into a high-impedance state to allow the pin to float.

### Backup-Battery Switchover

A power loss can be made less severe if the system RAM contents are preserved. This is achieved in the ASM690/692/ 802/805 by switching from the failed  $V_{CC}$  to an alternate power source connected at  $V_{BATT}$  when  $V_{CC}$  is less than the reset threshold voltage ( $V_{CC} < V_{RT}$ ), and  $V_{CC}$  is less than  $V_{BATT}$ . The  $V_{OUT}$  pin is normally connected to  $V_{CC}$  through a  $20\Omega$  PMOS switch but a brown-out or loss of  $V_{CC}$  will cause a switchover to  $V_{BATT}$  by means of a  $20\Omega$  PMOS switch. Although both conditions ( $V_{CC} < V_{RT}$  and  $V_{CC} < V_{BATT}$ ) must occur for the switchover to  $V_{BATT}$  to occur,  $V_{OUT}$  will be switched back to  $V_{CC}$  when  $V_{CC}$  exceeds  $V_{RT}$  irrespective of the voltage at  $V_{BATT}$ . It should be noted that an internal device diode (D1 in *Figure 3*) will be forward biased if  $V_{BATT}$  exceeds  $V_{CC}$  by more than a diode drop when  $V_{CC}$  is switched to  $V_{OUT}$ . Because of this it is recommended that  $V_{BATT}$  be no greater than  $V_{RT} + 0.6V$ .

Condition	SW1/SW2	SW3/SW4
$V_{CC} >$ Reset Threshold	Open	Closed
$V_{CC} <$ Reset Threshold $V_{CC} > V_{BATT}$	Open	Closed
$V_{CC} <$ Reset Threshold $V_{CC} < V_{BATT}$	Closed	Open
ASM690A/802A/805L Reset Threshold = 4.65V ASM692A /ASM802M Reset Threshold = 4.4V		

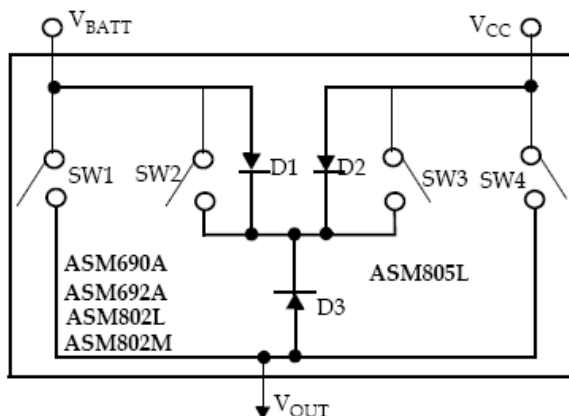

Figure 3: Internal device configuration of battery switch-over function

Table 1. Pin Connections in Battery Backup Mode

Pin	Connection
$V_{OUT}$	Connected to $V_{BATT}$ through internal PMOS switch
$V_{BATT}$	Connected to $V_{OUT}$
PFI	Disabled
$\overline{PFO}$	Logic-LOW
$\overline{RESET}$	Logic-LOW (except on ASM805 where it is HIGH)
WDI	Watchdog timer disabled

During the backup power mode, the internal circuitry of the supervisory circuit draws power from the battery supply. While  $V_{CC}$  is still alive, the comparator circuits remain alive and the current drawn by the device is typically  $35\mu A$ . When  $V_{CC}$  drops more than 1.1V below  $V_{BATT}$ , the internal switchover comparator, the PFI comparator and WDI comparator will shut off, reducing the quiescent current drawn by the IC to less than  $1\mu A$ .

### Backup Power Sources - Batteries

Battery voltage selection is important to insure that the battery does not discharge through the parasitic device diode D1 (see *Figure 3*) when  $V_{CC}$  is less than  $V_{BATT}$  and  $V_{CC} > V_{RT}$ .

**Table 2: Maximum Battery Voltages**

Part Number	MAXIMUM Battery Voltage (V)
ASM690A	4.80
ASM802L	4.80
ASM805L	4.80
ASM692A	4.55
ASM802M	4.55

Although most batteries that meet the requirements of *Table 2* are acceptable, lithium batteries are very effective backup source due to their high-energy density and very low self-discharge rates.

**Battery replacement while Powered**

Batteries can be replaced even when the device is in a powered state as long as  $V_{CC}$  remains above the reset threshold voltage  $V_{RT}$ . In the ASM devices, a floating  $V_{BATT}$  pin will not cause a powersupply switchover as can occur in some other supervisory circuits. If  $V_{BATT}$  is not used, the pin should be grounded.

**Backup Power Sources - SuperCap™**

Capacitor storage, with very high values of capacitance, can be used as a back-up power source instead of batteries. SuperCap™ are capacitors with capacities in the fractional farad range. A 0.1 farad SuperCap™ would provide a useful backup power source. Like the battery supply, it is important that the capacitor voltage remain below the maximum voltages shown in *Table 2*. Although the circuit of *Figure 4* shows the most simple way to connect the SuperCap™, this circuit cannot insure that an over voltage condition will not occur since the capacitor will ultimately charge up to  $V_{CC}$ . To insure that an over voltage condition does not occur, the circuit of *Figure 5* is preferred. In this circuit configuration, the diode-resistor pair clamps the capacitor voltage at one diode drop below  $V_{CC}$ .  $V_{CC}$  itself should be regulated within  $\pm 5\%$  of 5V for

the ASM692A/802M or within  $\pm 10\%$  of 5V for the ASM690A/802L/805L to insure that the storage capacitor does not achieve an over voltage state.

Note: SuperCap™ is a trademark of Baknor Industries

Figure 4: Capacitor as a backup power source

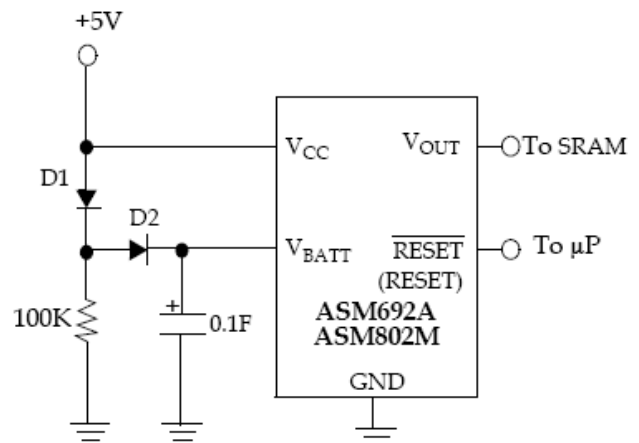

Figure 5: Capacitor as a backup power source  
Voltage clamped to 0.5V below  $V_{CC}$

**Operation without a Backup Power Source**

When operating without a back-up power source, the  $V_{BATT}$  pin should be connected to GND and  $V_{OUT}$  should be connected to  $V_{CC}$ , since power source switchover will not occur. Connecting  $V_{OUT}$  to  $V_{CC}$  eliminates the voltage drop due to the ON-resistance of the PMOS switch.

April 2008  
rev 1.7

**Power-Fail Comparator**

The Power Fail feature is an independent voltage monitoring function that can be used for any number of monitoring activities. The PFI function can provide an early sensing of power supply failure by sensing the voltage of the unregulated DC ahead of the regulated supply sensing seen by the backup-battery switchover circuitry. The PFI pin is compared to a 1.25V internal reference. If the voltage at the PFI pin is less than this reference voltage, the  $\overline{\text{PFO}}$  pin goes low. By sensing the voltage of the raw DC power supply, the microprocessor system can prepare for imminent power-loss, especially if the battery backup supply is not enabled. The input voltage at the PFI pin results from a simple resistor voltage divider as shown in Figure 6.

Figure 6: Simple Voltage divider sets PFI trip point

**Power Fail Hysteresis**

A noise margin can be added to the simple monitoring circuit of Figure 6 by adding positive feedback from the  $\overline{\text{PFO}}$  pin. The circuit of Figure 7 adds this positive “latching” effect by means of an additional resistor R3 connected between  $\overline{\text{PFO}}$  and PFI which helps in pulling PFI in the direction of  $\overline{\text{PFO}}$  and eliminating an indecision at the trip point. Resistor R3 is normally about 10 times higher in resistance than R2 to keep the hysteresis band

reasonable and should be larger than 10kΩ to avoid excessive loading on the PFO pin. The calculations for the correct values of resistors to set the hysteresis thresholds are given in Figure 7. A capacitor can be added to offer additional noise rejection by low-pass filtering.

Figure 7: Hysteresis Added To PFI Pin

**Monitoring Capabilities Of The Power-fail Input:**

Although designed for power supply failure monitoring, the PFI pin can be used for monitoring any voltage condition that can be scaled by means of a resistive divider. An example is the negative power supply monitor configured in Figure 8. In this case a good negative supply will hold the PFI pin below 1.25V and the  $\overline{\text{PFO}}$  pin

April 2008  
rev 1.7

will be at logic "0". As the negative voltage declines, the voltage at the PFI pin will rise until it exceeds 1.25V and the  $\overline{\text{PFO}}$  pin will go to logic "1".

<b>ASM802M</b>				
ASM802MCPAF	4.25 to 4.50	0 to +70	8-Plastic DIP	ASM802MCPAF
ASM802MCSAF	4.25 to 4.50	0 to +70	8-SO	ASM802MCSAF
ASM802MEPAF	4.25 to 4.50	-40 to +85	8-Plastic DIP	ASM802MEPAF
ASM802MESAF	4.25 to 4.50	-40 to +85	8-SO	ASM802MESAF
<b>ASM805L</b>				
ASM805LCPAF	4.5 to 4.75	0 to +70	8-Plastic DIP	ASM805LCPAF
ASM805LCSAF	4.5 to 4.75	0 to +70	8-SO	ASM805LCSAF
ASM805LEPAF	4.5 to 4.75	-40 to +85	8-Plastic DIP	ASM805LEPAF
ASM805LESFAF	4.5 to 4.75	-40 to +85	8-SO	ASM805LESFAF

Notes:

- For parts to be packed in Tape and Reel, add "-T" at the end of the part number.
- PulseCore Semiconductor's lead free parts are RoHS compliant.
