

Features

- **SuperBIG HIGH DENSITY IN-SYSTEM PROGRAMMABLE LOGIC**
 - 5V Power Supply
 - 45,000 PLD Gates/840 Macrocells
 - Up to 312 I/O Pins Supporting 3.3V/5V I/O
 - 1152 Registers
 - High-Speed Global and Big Fast Megablock (BFM) Interconnect
 - Wide 20-Macrocell Generic Logic Block (GLB) for High Performance
 - Wide Input Gating (44 Inputs per GLB) for Fast Counters, State Machines, Address Decoders, Etc.
 - PCB-Efficient Ball Grid Array (BGA) Package Options
- **HIGH-PERFORMANCE E²CMOS[®] TECHNOLOGY**
 - $f_{max} = 110$ MHz Maximum Operating Frequency
 - $t_{pd} = 8.5$ ns Propagation Delay
 - TTL Compatible Inputs and 3.3V/5V Outputs
 - PCI Compatible Inputs, Outputs and Speed Grades
 - Electrically Erasable and Reprogrammable
 - Non-Volatile
 - Programmable Speed/Power Logic Path Optimization
- **IN-SYSTEM PROGRAMMABLE**
 - Increased Manufacturing Yields, Reduced Time-to-Market and Improved Product Quality
 - Reprogram Soldered Devices for Faster Debugging
- **100% IEEE 1149.1 BOUNDARY SCAN TESTABLE AND 5V IN-SYSTEM PROGRAMMABLE**
- **ARCHITECTURE FEATURES**
 - Enhanced Pin-Locking Architecture, Symmetrical Generic Logic Blocks Connected by Hierarchical Big Fast Megablock and Global Routing Planes
 - Product Term Sharing Array Supports up to 28 Product Terms per Macrocell Output
 - Macrocells Support Concurrent Combinatorial and Registered Functions
 - Embedded Tristate Bus Can Be Used as an Internal Tristate Bus or as an Extension of an External Tristate Bus
 - Macrocell and I/O Registers Feature Multiple Control Options, Including Set, Reset and Clock Enable
 - I/O Pins Support Programmable Bus Hold, Pull-Up, Open-Drain and Slew Rate Options
 - Separate VCCIO Power Supply for Output Drivers Supports 5V or 3.3V Outputs
 - I/O Cell Register Programmable as Input Register for Fast Setup Time or Output Register for Fast Clock to Output Time

- **ispDesignEXPERT[™] – LOGIC COMPILER AND COMPLETE ISP DEVICE DESIGN SYSTEMS FROM HDL SYNTHESIS THROUGH IN-SYSTEM PROGRAMMING**
 - Superior Quality of Results
 - Tightly Integrated with Leading CAE Vendor Tools
 - Productivity Enhancing Timing Analyzer, Explore Tools, Timing Simulator and ispANALYZER[™]
 - PC and UNIX Platforms

Functional Block Diagram

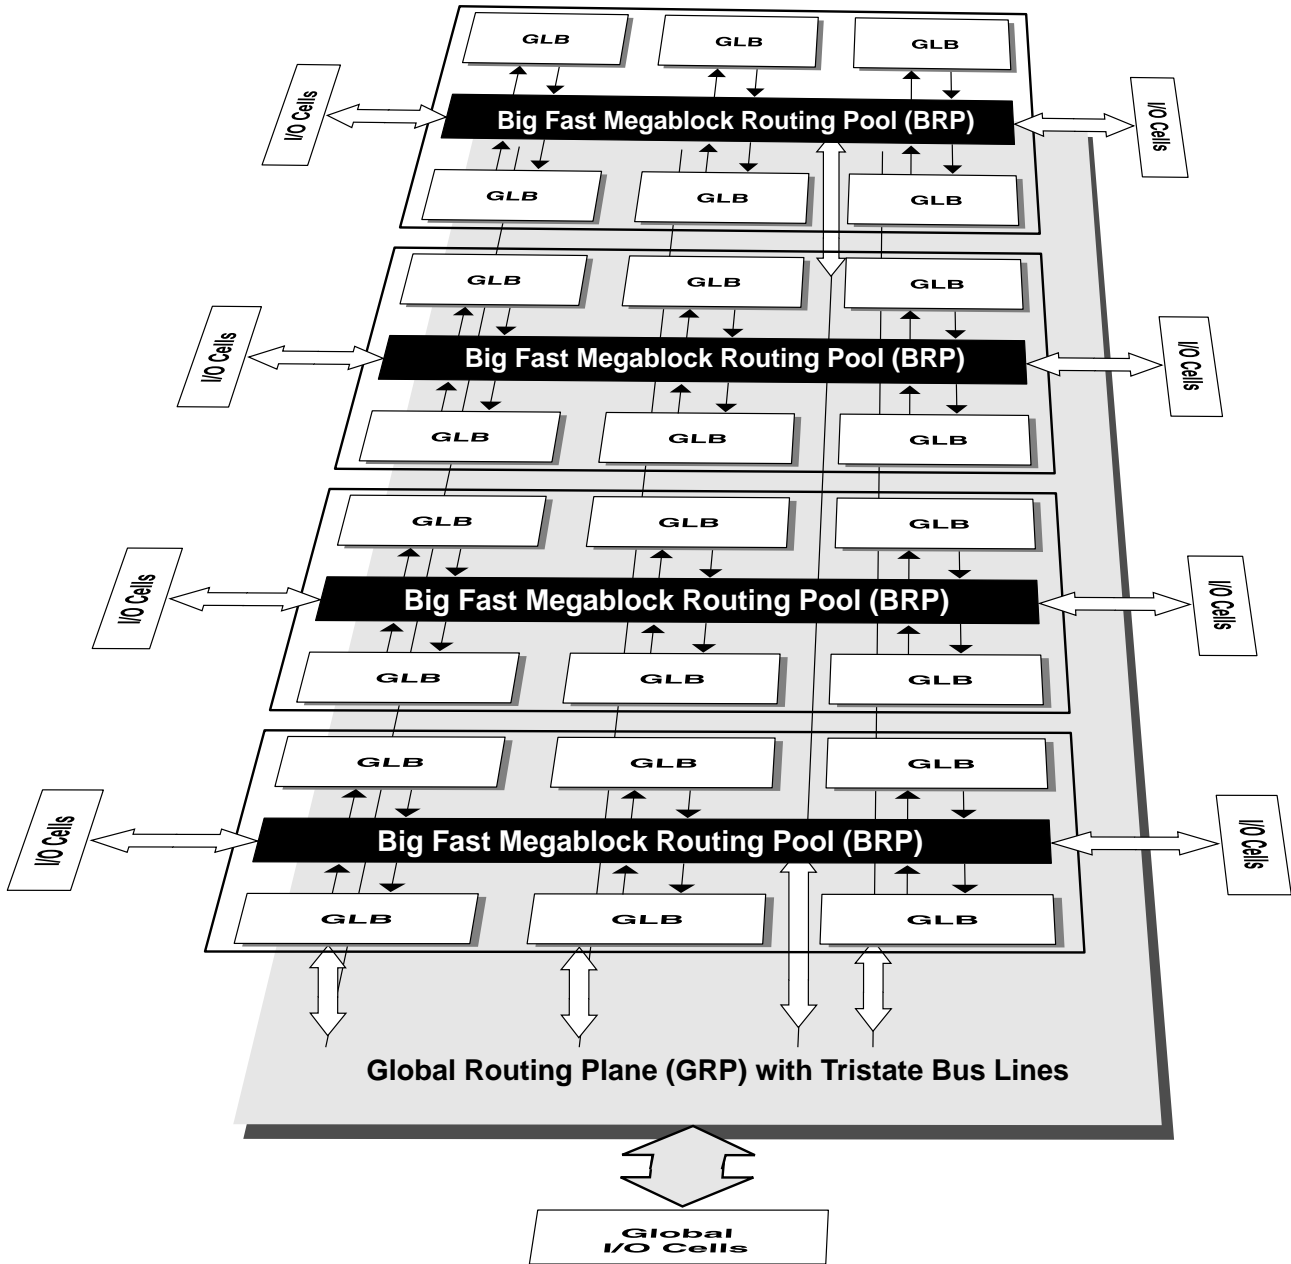

ispLSI 8000 Family Description

The ispLSI 8000 Family of Register-Intensive, SuperBIG In-System Programmable Logic Devices is based on Big Fast Megablocks of 120 registered macrocells and a Global Routing Plane (GRP) structure interconnecting the Big Fast Megablocks. Each Big Fast Megablock contains 120 registered macrocells arranged in six groups of 20, a group of 20 being referred to as a Generic Logic Block, or GLB. Within the Big Fast Megablock, a Big Fast Megablock Routing Pool (BRP) interconnects the six GLBs to each other and to 24 Big Fast Megablock I/O

Functional Block Diagram

Figure 1. ispLSI 8840 Functional Block Diagram (Perspective)

ispLSI 8000 Family Description (Continued)

cells with optional I/O registers. The Global Routing Plane which interconnects the Big Fast Megablocks has an additional 144 global I/Os with optional I/O registers.

Outputs from the GLBs in a Big Fast Megablock can drive both the Big Fast Megablock Routing Pool within the Big Fast Megablock and the Global Routing Plane between the Big Fast Megablocks. Switching resources are provided to allow signals in the Global Routing Plane to drive any or all the Big Fast Megablocks in the device. This mechanism allows fast, efficient connections, both within the Big Fast Megablocks and between them.

Each GLB contains 20 macrocells and a fully populated, programmable AND-array with 82 logic product terms. The GLB has 44 inputs from the Big Fast Megablock Routing Pool which are available in both true and complement form for every product term. Up to 20 of these inputs can be switched to provide local feedback into the GLB for logic functions that require it. The 80 general-purpose product terms can be grouped into 20 sets of four and sent into a Product Term Sharing Array (PTSA) which allows sharing up to a maximum of 28 product terms for a single function. Alternatively, the PTSA can be bypassed for functions of four product terms or less.

The 20 registered macrocells in the GLB are driven by the 20 outputs from the PTSA or the PTSA bypass. Each macrocell contains a programmable XOR gate, a programmable register/latch/toggle flip-flop and the necessary clocks and control logic to allow combinatorial or registered operation. Each macrocell has two outputs, one output can be fed back inside the GLB to the AND-array, while the other output drives both the Big Fast Megablock Routing Pool and the Global Routing Plane. This dual output capability from the macrocell allows efficient use of the hardware resources. One output can be a registered function for example, while the other output can be an unrelated combinatorial function.

Macrocell registers can be clocked from one of several global, local or product term clocks available on the device. A global, local and product term clock enable is also provided, eliminating the need to gate the clock to the macrocell registers. Reset and preset for the macrocell register is provided from both global and product term signals. The polarity of all of these control signals is selectable on an individual macrocell basis. The macrocell register can be programmed to operate as a D-type register, a D-type flow-through latch or a T-type flip flop.

The 20 outputs from the GLB can drive both the Big Fast Megablock Routing Pool within the Big Fast Megablock

and the Global Routing Plane between the Big Fast Megablocks. The Big Fast Megablock Routing Pool contains general purpose tracks which interconnect the six GLBs within the Big Fast Megablock and dedicated tracks for the signals from the Big Fast Megablock I/O cells. The Global Routing Plane contains general purpose tracks that interconnect the Big Fast Megablocks and also carry the signals from the I/Os connected to the Global Routing Plane.

Control signals for the I/O cell registers are generated using an extra product term within each GLB, or using dedicated input pins. Each GLB has two extra product terms beyond the 80 available for the macrocell logic. The first additional product term is used as an optional shared product term clock for all the macrocells within the GLB. The second additional product term is then routed to an I/O Control Bus using a separate routing structure from the Big Fast Megablock Routing Pool and Global Routing Plane. Use of a separate control bus routing structure allows the I/O registers to have many control signals with no impact on the interconnection of the GLBs and Big Fast Megablocks. The I/O Control Bus is split into four quadrants, each servicing the I/O cell control requirements for one edge of the device. Signals in the control bus can be independently selected by any or all I/O cells to act as clock, clock enable, output enable, reset or preset.

Each Big Fast Megablock has 24 I/O cells. The Global Routing Pool has 144 I/O cells. Each I/O cell can be configured as a combinatorial input, combinatorial output, registered input, registered output or bidirectional I/O. I/O cell registers can be clocked from one of several global, local or product term clocks which are selected from the I/O control bus. A global and product term clock enable is also provided, eliminating the need for the user to gate the clock to the I/O cell registers. Reset and preset for the I/O cell register is provided from both global and product term signals. The polarity of all of these control signals is selectable on an individual I/O cell basis. The I/O cell register can be programmed to operate as a D-type register or a D-type latch.

Inputs and outputs are PCI compatible. The input threshold is fixed at TTL levels. The output driver can source 4mA and sink 8mA. The output drivers have a separate VCCIO power supply which is independent of the main VCC supply for the device. This feature allows the output drivers to run from either 5V or 3.3V while the device logic is always powered from 5V. The output drivers also provide individually programmable edge rates and open

ispLSI 8000 Family Description (Continued)

drain capability. A programmable pullup resistor is provided to tie off unused inputs and a programmable bus-hold latch is available to hold tristate outputs in their last valid state until the bus is driven again by another device.

The ispLSI 8000 Family features 5V, non-volatile in-system programmability for both the logic and the interconnect structures, providing the means to develop truly reconfigurable systems. Programming is achieved through the industry standard IEEE 1149.1-compliant Boundary Scan interface using either the JTAG protocol or Lattice proprietary ISP protocol. Boundary Scan test is also supported through the same interface.

An enhanced, multiple cell security scheme is provided that prevents reading of the JEDEC programming file when secured. After the device has been secured using this mechanism, the only way to clear the security is to execute a bulk-erase instruction.

ispLSI 8840 Description

The ispLSI 8840 device has seven Big Fast Megablocks for a total of $7 \times 120 = 840$ macrocells.

Each Big Fast Megablock has a total of 24 I/O cells and the Global Routing Plane has a total of 144 I/O cells. This gives $(7 \times 24) + 144 = 312$ I/Os.

The total registers in the device is the sum of macrocells plus I/O cells, $840 + 312 = 1152$ registers.

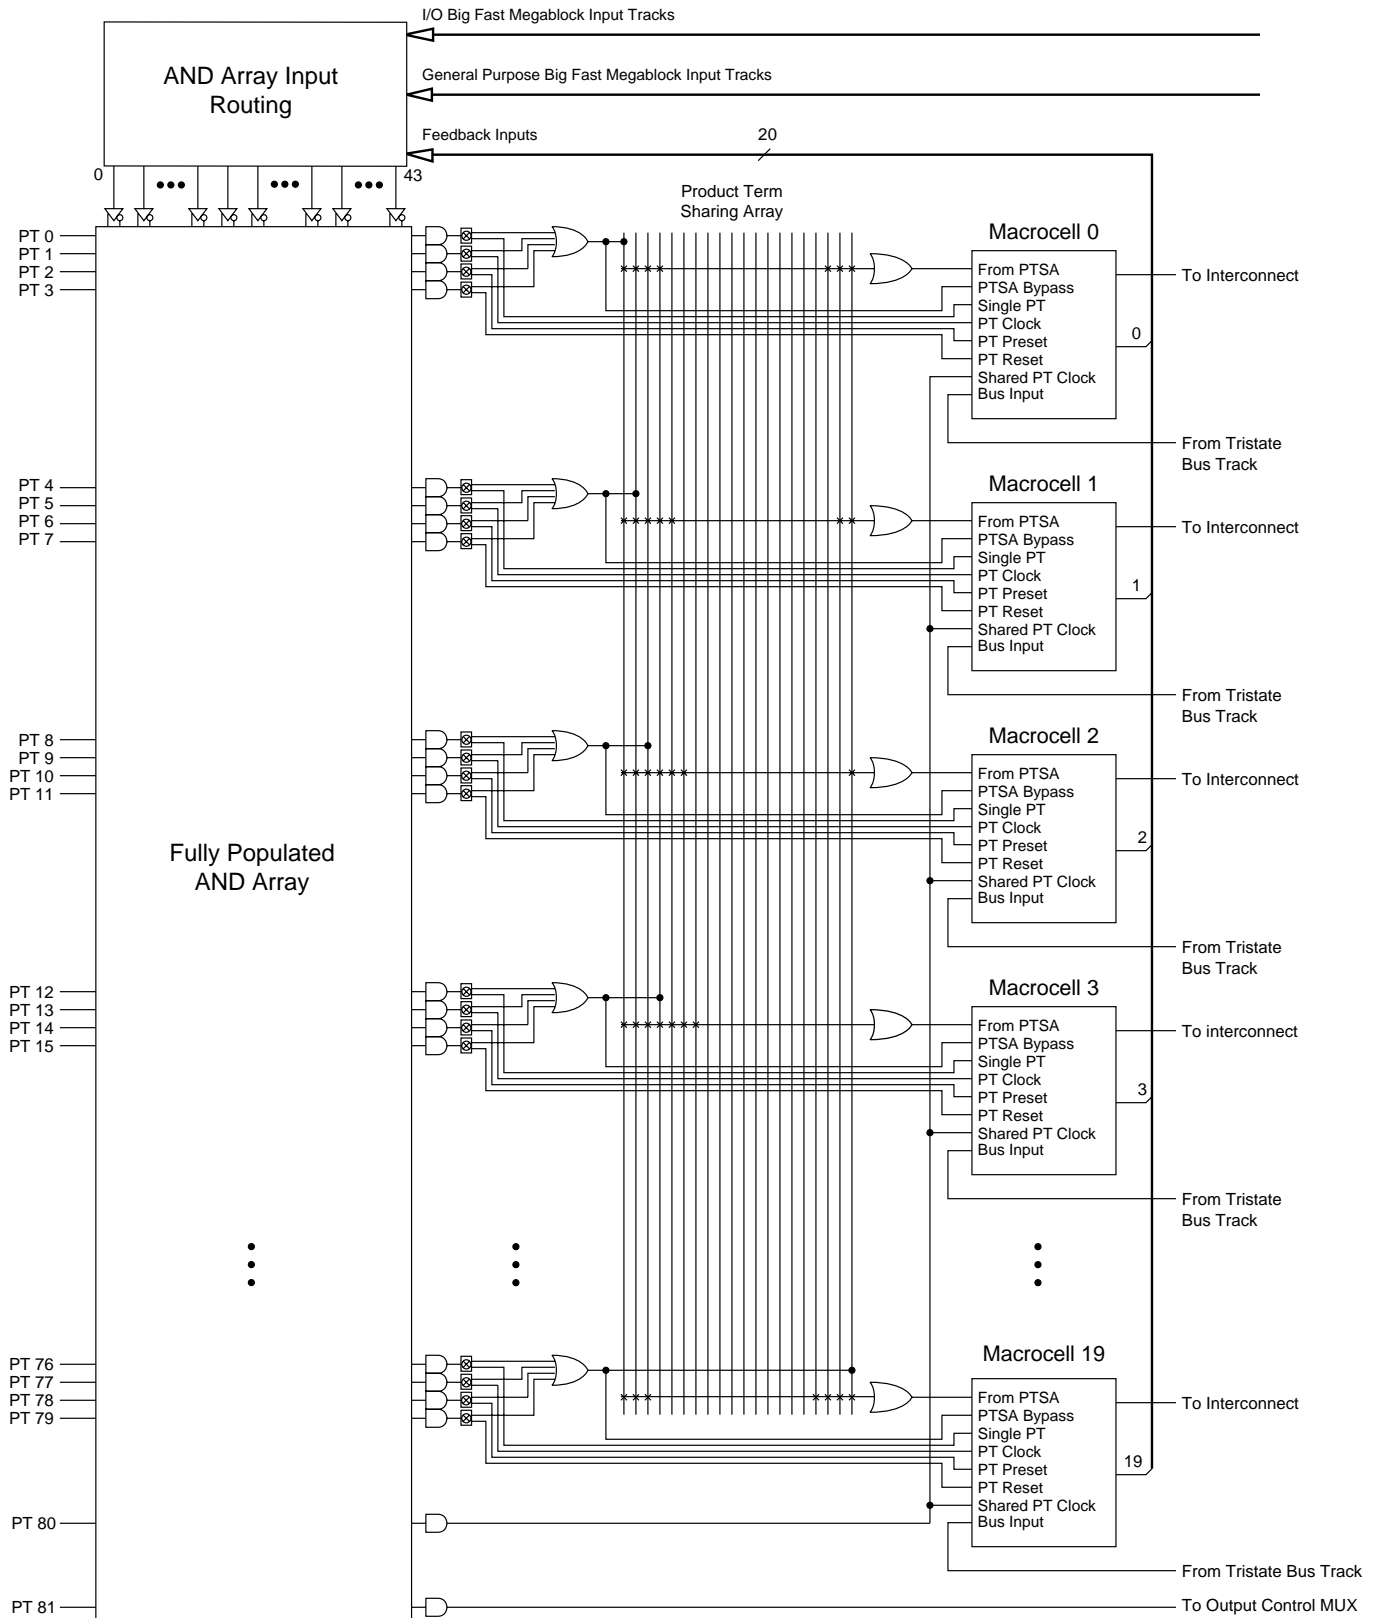

Embedded Tristate Bus

There is a 108-line embedded internal tristate bus as part of the Global Routing Plane (GRP), enabling multiple GLBs to drive the same tracks. This bus can be partitioned into various bus widths such as twelve 9-line buses, six 18-line buses or three 36-line buses. The GLBs can dynamically share a subset of the Global Routing Plane tracks. This feature eliminates the need to convert tristate buses to wide multiplexers on the programmable device. Up to 18 macrocells per GLB can

participate in driving the embedded tristate bus. The remaining two macrocells per GLB are used to generate the internal tristate driver control signals on each data byte (with parity). The embedded tristate bus can also be configured as an extension of an external tristate bus using the bidirectional capability of the I/O cells connected to the Global Routing Plane. The Global Routing Plane I/Os 0-8 and 15-23 from each group (I/OGx as defined in the I/O Pin Location Table) can connect to the internal tristate bus as well as the unidirectional/non-tristate global routing channels. I/Os 9-14 connect only to the global routing channel.

The embedded tristate bus has internal bus hold and arbitration features in order to make the function more "user friendly". The bus hold feature keeps the internal bus at the previously driven logic state when the bus is not driven to eliminate bus float. The bus arbitration is performed on a "first come, first served" priority. In other words, once a logic block drives the bus, other logic blocks cannot drive the bus until the first releases the bus. This arbitration feature prevents internal bus contention when there is an overlap between two bus enable signals. Typically, it takes about 3ns to resolve one bus signal coming off the bus to another bus signal driving the bus. The arbitration feature combined with the predictability of CPLD, makes the embedded tristate bus the most practical for the real world bus implementations.

Figure 2. ispLSI 8000 GLB Overview

Note: Macrocells 9 and 10 do not support Tristate Bus Feedback.

Output Control Organization

In addition to the data input and output to the I/O cells, each I/O cell can have up to six different I/O cell control signals. In addition to the internal OE control, the five control signals for each I/O cell consist of pin OE control, clock enable, clock input, asynchronous preset and asynchronous reset. All of the I/O control signals can be driven either from the dedicated external input pins or from the internal control bus.

The output enable of each I/O cell can be driven by 21 different sources – 16 from the output control bus, four from the Global OE pins and one from the Test OE pin.

The Global OE signals and Test OE signal are driven from the dedicated external control input pins.

The 16-bit wide output control buses are organized in four different quadrants as shown in Figure 5. Since each GLB is capable of generating the output control signals, each of the output control bus signals can be driven from a unique GLB. The 42 GLBs can generate a total of 42 unique I/O control signals. Referring to Figure 2, the GLB generates its output control signal from control product term (PT81).

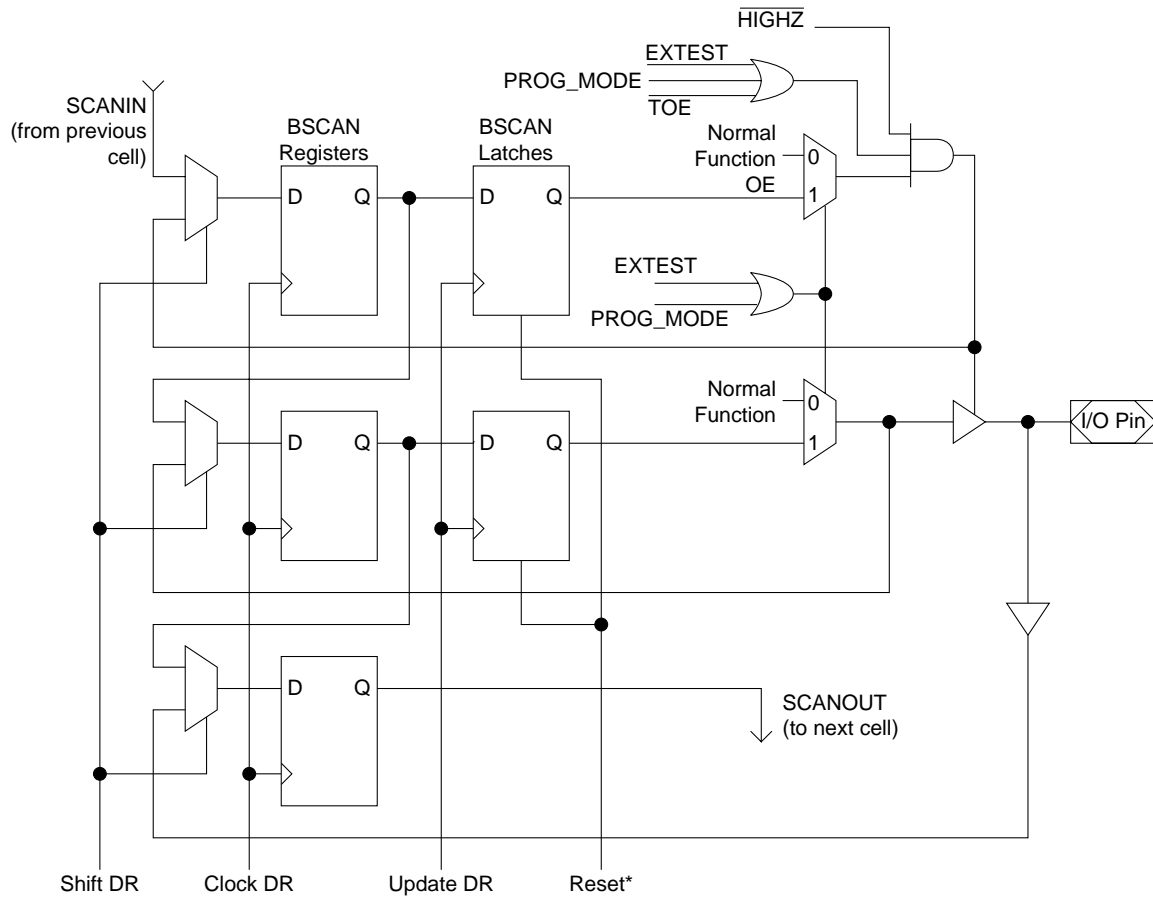

Figure 5 also illustrates how the quadrant clocks are routed to the appropriate quadrant I/O cells.

t _{giorst}	86	Global I/O Cell Register Reset	–	4.6	–	5.9	–	8.8	ns

1. Internal Timing Parameters are not tested and are for reference only.
2. Refer to Timing Model in this data sheet for further details.

ispLSI 8840 Timing Model

Example Timing Calculations

$$\begin{aligned}
 \mathbf{tpd1} &= (\text{BFM Input Path Delay}) + (\text{GLB Delay}) + (\text{Output Path Delay}) \\
 &= (\mathbf{t_{idcom}} + \mathbf{t_{ibp}} + \mathbf{t_{bfmi}}) + (\mathbf{t_{andhs}} + \mathbf{t_{4ptcom}} + \mathbf{t_{mbp}}) + (\mathbf{t_{bfmm}} + \mathbf{t_{bcom}} + \mathbf{t_{obp}} + \mathbf{t_{odcom}} + \mathbf{t_{slf}}) \\
 &= (\#23 + \#26 + \#61) + (\#39 + \#42 + \#45) + (\#64 + \#69 + \#25 + \#35 + \#37) \\
 &= (0.1 + 0.2 + 0.2) + (3.6 + 0.2 + 0.0) + (1.9 + 0.5 + 0.0 + 1.7 + 0.0) \\
 &= 8.4 \text{ ns}
 \end{aligned}$$

$$\begin{aligned}
 \mathbf{tpd} \text{ (within BFM)} &= (\text{BFM Delay}) + (\text{GLB Delay}) \\
 &= (\mathbf{t_{bfmm}}) + (\mathbf{t_{andhs}} + \mathbf{t_{4ptcom}} + \mathbf{t_{mbp}}) \\
 &= (\#64) + (\#39 + \#42 + \#45) \\
 &= (1.9) + (3.6 + 0.2 + 0.0) \\
 &= 5.7 \text{ ns}
 \end{aligned}$$

$$\begin{aligned}
 \mathbf{tpd} \text{ (between BFMs)} &= (\text{GRP Delay}) + (\text{BFM Delay}) + (\text{GLB Delay}) \\
 &= (\mathbf{t_{grpm}}) + (\mathbf{t_{bfmg}}) + (\mathbf{t_{andhs}} + \mathbf{t_{4ptcom}} + \mathbf{t_{mbp}}) \\
 &= (\#65) + (\#67) + (\#39 + \#42 + \#45) \\
 &= (2.0) + (1.6) + (3.6 + 0.2 + 0.0) \\
 &= 7.4 \text{ ns}
 \end{aligned}$$

$$\begin{aligned}
 \text{BFM I/O to internal tri-state Enable/Disable} &= (\text{BFM Input Path Delay}) + (\text{GLB Delay, 1PT}) + (\text{Tri-state Control Delay}) \\
 &= (\mathbf{t_{idcom}} + \mathbf{t_{ibp}} + \mathbf{t_{bfmi}}) + (\mathbf{t_{andhs}} + \mathbf{t_{1pt}} + \mathbf{t_{mbp}}) + (\mathbf{t_{grpmz}}) \\
 &= (\#23 + \#26 + \#61) + (\#39 + \#41 + \#45) + (\#66) \\
 &= (0.1 + 0.2 + 0.2) + (3.6 + 3.6 + 0.0) + (4.0) \\
 &= 11.7 \text{ ns}
 \end{aligned}$$

$$\begin{aligned}
 \mathbf{tsu1} &= (\text{BFM Input Path Delay}) + (\text{GLB Setup Time}) - (\text{Min. Global Clock Delay}) \\
 &= (\mathbf{t_{idcom}} + \mathbf{t_{ibp}} + \mathbf{t_{bfmi}}) + (\mathbf{t_{andhs}} + \mathbf{t_{4ptreg}} + \mathbf{t_{msu}}) - (\mathbf{t_{gck \text{ min}}}) \\
 &= (\#23 + \#26 + \#61) + (\#39 + \#43 + \#48) - (\#78) \\
 &= (0.1 + 0.2 + 0.2) + (3.6 + 3.4 + 0.4) - (2.9) \\
 &= 5 \text{ ns}
 \end{aligned}$$

$$\begin{aligned}
 1/\mathbf{F_{max}} &= (\text{Global Clk to MC Output}) + (\text{Local Feedback}) + (\text{GLB Setup Time}) \\
 &= (\mathbf{t_{mco}}) + (\mathbf{t_{floc}}) + (\mathbf{t_{andhs}} + \mathbf{t_{ptsa}} + \mathbf{t_{msu}}) \\
 &= (\#47) + (\#54) + (\#39 + \#44 + \#48) \\
 &= (0.2) + (1.1) + (3.6 + 3.7 + 0.4) \\
 &= 9 \text{ ns}
 \end{aligned}$$

$$\mathbf{F_{max}} = 111 \text{ MHz}$$

Note: Calculations are based upon timing specifications for the ispLSI 8840-110L

Power Consumption

Power consumption in the ispLSI 8840 device depends on two primary factors: the speed at which the device is operating and the number of product terms used. The product terms have a fuse-selectable speed/power tradeoff setting. Each group of four product terms has a single speed/power tradeoff control fuse that acts on the complete group of four. The fast “high-speed” setting

operates product terms at their normal full power consumption. For portions of the logic that can tolerate longer propagation delays, selecting the slower “low-power” setting will significantly reduce the power dissipation for these product terms. Figure 10 shows the relationship between power and operating speed.

Figure 10. Typical Device Power Consumption vs fmax

Notes: Configuration of 42 20-bit counters
Typical current at 5V, 25° C

ICC can be estimated for the ispLSI 8840 using the following equation:

$$I_{CC} = 48.0 + (\# \text{ of Turbo PTs} * 0.346) + (\# \text{ of Non-Turbo PTs} * 0.165) + (\# \text{ of Macrocells Used} * f_{max} * AF * 0.049)$$

of Turbo PTs = Number of Turbo Product Terms Used in Design

of Non-Turbo PTs = Number of Non-Turbo Product Terms Used in Design

fmax = Maximum Operating Frequency

$$AF \text{ (Activity Factor)} = \frac{\text{Average Macrocell Toggle Frequency}}{F_{max}}$$

Note: An Activity Factor of 1.0 means all macrocell registers toggle at Fmax. An Activity Factor of 0.5 means the average macrocell registers toggle at half of fmax.

The ICC estimate is based on typical conditions (VCC = 5.0V, room temperature) and an assumption of two GLB loads on average exists. These values are for estimates only. Since the value of ICC is sensitive to operating conditions and the program in the device, the actual ICC should be verified.

Signal Descriptions

Signal Name	Description
CLK0, CLK1, CLK2	Dedicated clock input for the GLB registers only. These clock inputs are connected to one of the clock inputs of all GLB registers in the device.
CLKEN	Dedicated clock enable input for the GLB registers only. This input is available as a clock enable for each GLB register in the device. Use of the clock enable input eliminates the need for the user to gate the clock to the register.
GIOCLK0, GIOCLK1	Dedicated clock inputs for the I/O registers only. These clock inputs are connected to one of the clock inputs of all I/O registers in the device.
GND	Ground (GND)
GOE	Global Output Enable inputs.
SET/RESET	Dedicated reset/preset pin connected to ALL registers in the device, GLB registers and I/O registers. Each register can independently choose to be reset or preset when this signal goes active. The active polarity is user-selectable.
IOCLKEN	Dedicated clock enable input for the I/O registers only. This input is available as a clock enable input for all I/O registers in the device. Use of the clock enable input eliminates the need for the user to tie the clock to the I/O register.
I/O	Input/Output – These are the general purpose I/O used by the logic array.
BSCAN/ $\overline{\text{ispEN}}$	Input – Dedicated in-system programming enable input. When this is high, the BSCAN TAP controller signals TMS, TDI, TDO and TCK are enabled. When this is brought low, the ISP State Machine control signals MODE, SDI, SDO and SLCK are enabled. High-to-low transition will put the device in the Lattice ISP programming mode and put all I/O in the high-Z state.
TMS/MODE	Input – This signal performs two functions. It is the Test Mode Select input signal when $\overline{\text{ispEN}}$ is logic high. When $\overline{\text{ispEN}}$ is logic low, it controls the operation of the ISP State Machine.
NC ¹	No connect.
QIOCLK0 QIOCLK1 QIOCLK2 QIOCLK3	Dedicated clock inputs for the I/O registers only. These clock inputs are connected to the I/O registers on the same side of the device only, they are not connected to all of the I/O registers. Use of these quadrant I/O clocks gives the fastest tco from the device.
TCK/SCLK	Input – This signal performs two functions. It is the Test Clock input signal when $\overline{\text{ispEN}}$ is logic high. When $\overline{\text{ispEN}}$ is logic low, it functions as a clock signal for the Serial Shift Register.
TDI/SDI	Input – This signal performs two functions. It is the Test Data input signal when $\overline{\text{ispEN}}$ is logic high. When $\overline{\text{ispEN}}$ is logic low, it functions as an input to load programming data into the device. SDI is also used as one of the two control signals for the ISP State Machine.
TDO/SDO	Output – This signal performs two functions. When $\overline{\text{ispEN}}$ is logic low, it reads the ISP data. When $\overline{\text{ispEN}}$ is high, it functions as Test Data Out.
TOE	Test Output Enable pin – This pin tristates all I/O pins when a logic low is driven.
VCC	Vcc
VCCIO	Power supply for the output drivers. The internal logic of the device is connected to VCC which is always 5V. The output drivers are connected to VCCIO which can be equal to VCC or 3.3V. This allows the output drivers to be powered from 3.3V, for example, to interface directly with another 3.3V device.

1. NC pins are not to be connected to any active signals, VCC or GND.
