Features

- Pulse-width Modulation up to 2 kHz Clock Frequency
- Protection against Short-circuit, Load-dump Overvoltage and Reverse $\rm V_S$
- Duty-cycle 0 to 100% Continuously
- Output Stage for Power MOSFET
- Interference and Damage Protection According to VDE 0839 and ISO/TR 7637/1
- Charge-pump Noise Suppressed
- Ground-wire Breakage Protection

Description

The U6084B is a PWM-IC with bipolar technology designed for the control of an N-channel power MOSFET used as a high-side switch. The IC is ideal for use in the brightness control (dimming) of lamps such as in dashboard applications. For constant brightness, the preselected duty-cycle can be reduced automatically as a function of the supply voltage.

Pin Description

Pin	Symbol	Function
1	GND	IC ground
2	EN/DIS	Enable/disable
3	VI	Control input (duty cycle)
4	REDUCT	Duty cycle reduction
5	NC	Attenuation
6	OSC	Oscillator
7	NC	Not connected
8	NC	Not connected
9	LATCH	Status short-circuit latch
10	NC	Not connected
11	DELAY	Short-circuit protection delay
12	SENSE	Current sensing
13	2VS	Voltage doubler
14	OUTPUT	Output
15	NC	Not connected
16	VS	Supply voltage V _S

U6084B

Functional Description

Pin1 – GND

Ground-wire Breakage To protect the FET in case of ground-wire breakage, a 820 k Ω resistor between gate and source is recommended to provide proper switch-off conditions.

Pin 2 – Enable/Disable

The dimmer can be switched on or off, with pin 2, independently of the set duty cycle.

Table 1. Pin 2 Function

V ₂	Function
Approximately > 0.7 V or open	Disable
< 0.7 V or connected to pin 1	Enable

Pin 3 – Control Input The pulse width is controlled by means of an external potentiometer (47 k Ω). The characteristic (angle of rotation/duty cycle) is linear. The duty cycle be varied from 0 to 100%. It is possible to further restrict the duty cycle with resistors R₁ and R₂ (see Figure 3 on page 8).

Pin 3 is protected against short-circuit to V_{Batt} and ground GND ($V_{Batt} \le 16.5 \text{ V}$).

Pin 4 – Duty CycleWith pin 4 connected according to Figure 3 on page 8, the set duty cycle is reduced to
 $V_{Batt} \approx 12.5 \text{ V}$. This causes a power reduction in the FET and in the lamps. In addition,
the brightness of the lamps is largely independent of the supply voltage range,
 $V_{Batt} = 12.5 \text{ to } 16 \text{ V}$.

Output Slope Control The rise and fall time (t_r, t_f) of the lamp voltage can be limited to reduce radio interference. This is done with an integrator which controls a power MOSFET as source follower. The slope time is controlled by an external capacitor C_4 and the oscillator current (see Figure 3 on page 8).

Calculation:

$$t_{f} = t_{r} = V_{Batt} \times \frac{C_{4}}{I_{osc}}$$

With $V_{Batt} = 12$ V, $C_4 = 470$ pF and $I_{osc} = 40 \ \mu$ A, we thus obtain a controlled slope of $t_f = t_r = 12$ V × $\frac{470 \ pF}{40 \ \mu A}$ × 141 μ s

Pin 5 – Attenuation Capacitor C₄ connected to pin 5 damps oscillation tendencies.

Pin 6 – OscillatorThe oscillator determines the frequency of the output voltage. This is defined by an
external capacitor, C_2 . It is charged with a constant current, I, until the upper switching
threshold is reached. A second current source is then activated which taps a double cur-
rent, $2 \times I$, from the charging current. The capacitor, C_2 , is thus discharged by the
current, I, until the lower switching threshold is reached. The second source is then
switched off again and the procedure starts once more.

Example for Oscillator **Frequency Calculation**

 $V_{T100} = V_S \times \alpha_1 = (V_{Batt} - I_S \times R_3) \times \alpha_1$ $V_{T<100} = V_S \times \alpha_2 = (V_{Batt} - I_S \times R_3) \times \alpha_2$ $V_{TL} = V_S \times \alpha_3 = (V_{Batt} - I_S \times R_3) \times \alpha_3$ where

 V_{T100} = High switching threshold 100% duty cycle

 $V_{T<100}$ = High switching threshold < 100% duty cycle

 V_{TI} = Low switching threshold

 α_1 , α_2 and α_3 are fixed values

The above mentioned threshold voltages are calculated for the following values given in the datasheet.

$$V_{Batt} = 12 \text{ V}, \text{ I}_{S} = 4 \text{ mA}, \text{ R}_{3} = 150 \Omega,$$

 $\alpha_{1} = 0.7, \alpha_{2} = 0.67 \text{ and } \alpha_{3} = 0.28.$
 $V_{T100} = (12 \text{ V} - 4 \text{ mA} \times 150 \Omega) \times 0.7 \approx 8 \text{ V}$
 $V_{T<100} = 11.4 \text{ V} \times 0.67 = 7.6 \text{ V}$
 $V_{TL} = 11.4 \text{ V} \times 0.28 = 3.2 \text{ V}$
For a duty cycle of 100%, the assillator frequency

For a duty cycle of 100%, the oscillator frequency, f, is as follows:

$$f = \frac{I_{osc}}{2 \times (V_{T100} - V_{TL}) \times C_2}$$
 where C₂ = 22 nF and I_{osc} = 40 µA

Therefore:

. .

 $f = \frac{40 \ \mu A}{2 \times (8 \ V - 3.2 \ V) \times 22 \ nF} = 189 \ Hz$

For a duty cycle of less than 100%, the oscillator frequency, f, is as follows:

$$f = \frac{I_{osc}}{2 \times (V_{T < 100} - V_{TL}) \times C_2 + 4 \times V_{Batt} \times C_4}$$

where $C_4 = 470 \text{ pF}$ $f = \frac{40 \,\mu\text{A}}{2 \times (7.6 \text{ V} - 3.2 \text{ V}) \times 22 \text{ nF} + 4 \times 12 \text{ V} \times 470 \text{ pF}} = 185 \text{ Hz}$

A selection of different values of C₂ and C₄ provides a range of oscillator frequencies from 10 to 2000 Hz.

Pins 7, 8, 10 and 15 Not connected.

Pin 9 – Status Short **Circuit Latch**

The status of the short-circuit latch can be monitored via pin 9 (open collector output).

Table 2. Pin 9 Function

Pin 9	Function	
L	Short-circuit detected	
Н	Not short-circuit detected	

U6084B

Pins 11 and 12 – Short-circuit Protection and Current Sensing

Short-circuit Detection and Time Delay t _d	The lamp current is monitored by means of an external shunt resistor. If the lamp current exceeds the threshold for the short-circuit detection circuit ($V_{T2} \approx 90 \text{ mV}$), the duty cycle is switched over to 100% and capacitor C_5 is charged by a current source of 20 μ A ($I_{ch} - I_{dis}$). The external FET is switched off after the cut-off threshold (V_{T11}) is reached. Renewed switching on the FET is possible only after a power-on reset. The current source, I_{dis} , ensures that capacitor C_5 is not charged by parasitic currents. Capacitor C_5 is discharged by I_{dis} to typ. 0.7 V. Time delay, t_d , is as follows: $t_d = C_5 \times \frac{(V_{11} - 0.7 \text{ V})}{(I_{ch} - I_{dis})}$ With $C_5 = 330 \text{ nF}$ and $V_{Batt} = 12 \text{ V}$, we have $t_d = 330 \text{ nF} \times \frac{(9.8 \text{ V} - 0.7 \text{ V})}{20 \mu \text{ A}} = 150 \text{ ms}$
Current Limitation	The lamp current is limited by a control amplifier that protects the external power transistor. The voltage drop across an external shunt resistor acts as the measured variable. Current limitation takes place for a voltage drop of $V_{T1} \approx 100 \text{ mV}$. Owing to the difference $V_T - V_{T2} \approx 10 \text{ mV}$, current limitation occurs only when the short-circuit detection circuit has responded.
	After a power-on reset, the output is inactive for half an oscillator cycle. During this time, the supply voltage capacitor can be charged so that current limitation is guaranteed in the event of a short-circuit when the IC is switched on for the first time.
Pins 13 and 14 – Charge Pump and Output	Pin 14 (output) is suitable for controlling a power MOSFET. During the active integration phase, the supply current of the operational amplifier is mainly supplied by capacitor C_3 (bootstrapping). Additionally, a trickle charge is generated by an integrated oscillator ($f_{13} \approx 400$ kHz) and a voltage doubler circuit. This permits a gate voltage supply at a duty cycle of 100%.
Pin 16 – Supply Voltage, V _s or V _{Batt}	
Undervoltage Detection	In the event of voltages of approximately V_{Batt} < 5.0 V, the external FET is switched off and the latch for short-circuit detection is reset.
	A hysteresis ensures that the FET is switched on again at approximately $V_{Batt} \geq 5.4~V.$
Overvoltage Detection	
Stage 1	If overvoltages of V_{Batt} > 20 V (typically) occur, the external transistor is switched off and switched on again at V_{Batt} < 18.5 V (hysteresis).
Stage 2	If $V_{Batt} > 28.5$ V (typically), the voltage limitation of the IC is reduced from 26 V to 20 V. The gate of the external transistor remains at the potential of the IC ground, thus pro- ducing voltage sharing between the FET and lamps in the event of overvoltage pulses (e.g., load-dump). The short-circuit protection is not in operation. At $V_{Batt} < 23$ V, the overvoltage detection stage 2 is switched off.

Absolute Maximum Ratings

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability

Parameters	Symbol	Value	Unit	
Junction temperature	Τ _j	150	°C	
Ambient temperature range	T _{amb}	-40 to +110	°C	
Storage temperature range	T _{stg}	-55 to +125	°C
