Advanced Micro Devices reserves the right to make changes in its products without notice in order to improve design or performance characteristics. The performance characteristics listed in this data sheet are guaranteed by specific tests, correlated testing, guard banding, design and other practices common to the industry. For specific testing details contact your local AMD sales representative. The company assumes no responsibility for the use of any circuits described herein.

Am79101

FSK AUTODIAL MODEM
WORLD-CHIP^{TM}

DISTINCTIVE CHARACTERISTICS

o   Bell 103, 113, 108 and CCITT V.21 compatible at 300 bps full-duplex

o   Bell 202 and CCITT V.23 compatible at 1200 bps half-duplex with up to 150 bps back channel (CCITT V.23 modes with optional soft carrier turn-off feature)

o   Single-chip digital signal processor

o   Autodial support
    -Dual Tone Multi-Frequency (DTMF) Tone Generation
    -Call Progress Tone Detection
    -Answer Tone Detection

o   Integral 4-to-2 wire hybrid

o   Public Switched Telephone Network (PSTN) response times

o   Serial RS-232C/CCITT V.24-type handshake interface and protocol

5

GENERAL DESCRIPTION

The Am79101 World-Chip is a single-chip asynchronous Frequency
Shift Keying (FSK) modem that is compatible with the applicable
Bell and CCITT-recommended standards for 103/113/108, 202, V.21
and V.23-type modems. All modulation, demodulation, filtering,
analog-to-digital and digital-to-analog functions are provided
on-chip.

Using the features described here, an intelligent Autodial,
Autoanswer FSK modem may be implemented with only an Am79101
single-chip under the control of a host microprocessor and a
Data Access Arrangement (DAA) circuit.

The modem operates in a serial asynchronous mode; the serial
interface supports the RS-232C/CCITT V.24-type handshake
signals at TTL levels.

The modem analog interface provides an internal hybrid for the
4-to-2 wire conversion. Auxiliary functions performed within
the Am79101 include:

-    Autodial support with DTMF generation and Call Progress
     Tone Detection.
-    Answer Tone Detection (Bell and CCITT).
-    Autoanswer support.
-    Analog loopback support.

The Am79101 is housed in a 28-pin plastic leaded chip carrier
as well as 28-pin plastic and ceramic dual-in-line packages.

Connection to the telephone network may be via a DAA or an
acoustic coupler. All digital I/O signals are TTL-compatible
(except the external clock and $\overline{RESET}$ signals) and the circuit
operates from +5 Volts.

ORDERING INFORMATION

Standard Products

AMD products are available in several packages and operating ranges. The order number (valid combination) is formed by a combination of the following:

      a. Device number
      b. Speed option (if applicable)
      c. Package type
      d. Temperature range
      e. Optional processing

<u>Am79101</u>   <u>D</u>   <u>C</u>   <u>B</u>

e. Optional Processing
Blank = Standard processing
B = Burn-in

d. Temperature Range
C = Commercial (0^oC to $+70^oC$)
I = Industrial (-40^oC to $+85^oC$)
E = Extended (-55^oC to $+125^oC$)

c. Package Type
D = 28-Pin Ceramic DIP (CD 028)
P = 28-Pin Plastic DIP (PD 028)
J = 28-Pin PLCC (PL 028)

a. AMD Device Type
FSK Modem

b. Speed Option
Not Applicable
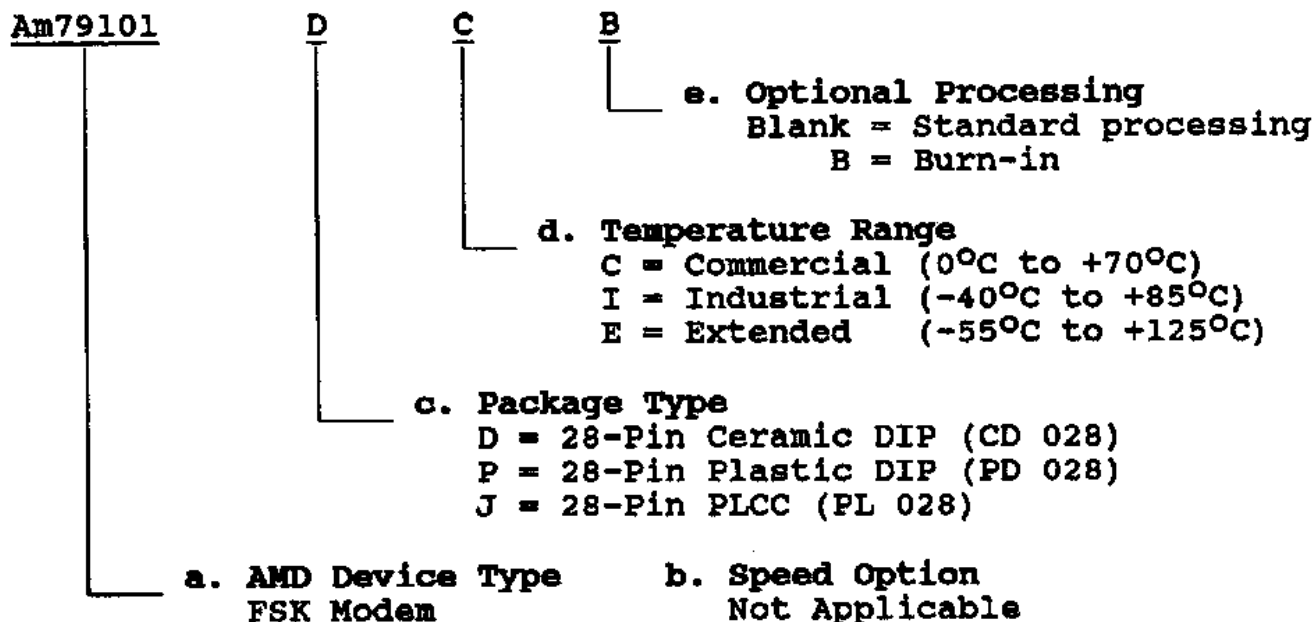

Valid Combinations	
Am79101	DC, DCB, DI, DIB, PC, DE, DEB, JC

Valid Combinations

Valid Combinations list configurations planned to be supported in volume for this device. Consult the local AMD sales office to confirm availability of specific valid combinations, to check on newly released valid combinations, and to obtain additional data on AMD's standard military grade products.

8

PIN DESCRIPTION

All digital inputs and outputs are TTL-compatible unless other-
wise noted.

SETUP CONTROLS

DA/$\overline{CA}$ Data/Call (Input)

This input selects the Data Mode (DA/$\overline{CA}$=HIGH) or the Call
Mode (DA/$\overline{CA}$=LOW). In the Data Mode, the Am79101 operates
as a modem, using other setup and handshake inputs. Data
Mode is the initial condition by default.

To enter the Call Mode, DA/$\overline{CA}$ is brought to a LOW while
$\overline{DTR}$ is HIGH and MC pins are set to a valid mode (i.e., not
reserved mode). Once in the Call Mode, $\overline{DTR}$ is set LOW.
MC inputs and $\overline{RTS}$ will determine the generation of either
DTMF or answer tones, and the detection of call progress
tones or answer tones. To re-enter the Data Mode, DA/$\overline{CA}$
is returned to a HIGH during a valid modem mode.

$\overline{DTR}$ Data Terminal Ready (Input)
A LOW level on this input indicates the data terminal is
ready to send and/or receive data via the modem. This
signal is gated with all other TTL inputs and outputs so
that a LOW level enables these signals as well as the
internal control logic. A HIGH disables all TTL I/O pins
and the internal logic.

When $\overline{DTR}$ is HIGH, the modem handshake state machine is
reset to initial conditions. This is the only way to
reset the state machine, and must be done after power-up.
The state machine does not automatically power up to a
known state. If $\overline{DTR}$ is permanently enabled (LOW), the
state machine will simply run from wherever it powers-up.
This can result in abnormal behavior such as an unusually
short $\overline{RTS}$-$\overline{CTS}$ delay due to lack of $\overline{DTR}$ initialization.

9

To change the modem mode when powered-up, use the following sequence: (See Figure 16)

1.   Set $\overline{\text{DTR}}$ HIGH

2.   Change MC inputs to desired configuration

3.   Wait at least 100 microseconds

4.   Set $\overline{\text{DTR}}$ LOW

The MC inputs perform some hardware functions and are also sampled periodically by the state machine. If the MC inputs are changed without re-initialization using $\overline{\text{DTR}}$, the state machine will not completely change to the new mode. In the Call Mode, $\overline{\text{DTR}}$ does not have to be changed when going from one DTMF digit to another.

MC_0-MC_4 Mode Controls (Inputs)

In the Data Mode, the MC inputs specify one of the 25 available modem configurations as listed in Table 1a. Included are Bell 103/202, CCITT V.21/V.23 with various options like equalizer, 150 bps back channel, soft turn-off and loopback.

The loopback modes set the signal processing frequency band of the receiver to that of the transmitter. The user must connect TC to RC for analog loopback, and RD to TD for digital loopback as shown in Figure 1.

In the Call Mode, the MC inputs select generation of DTMF or answer tones, or detection of call progress tones or answer tones, as listed in Table 1b.

None of the reserved modes should be used.

TRANSMITTER I/O

$\overline{\text{BCTS}}$ $\overline{\text{Back Clear To Send}}$ (Output)

This line is equivalent to $\overline{\text{CTS}}$ for the main channel, except that it applies only to the back channel. $\overline{\text{BCTS}}$ is meaningful only when a V.23 mode or 202 150bps (or 75bps) back channel mode is selected by MC_0-MC_4. This signal is not used in the 202 5bps back channel mode.

10

$\overline{\text{BRTS}}$ Back Request To Send (Input)

Since the 1200bps modem configurations, Bell 202 and CCITT V.23, permit only half-duplex operation over 2-wire lines, a low baud rate back channel is provided for simultaneous transmission in the reverse direction. $\overline{\text{BRTS}}$ is directly equivalent to main channel $\overline{\text{RTS}}$, except that it applies only to the back channel. Note that since the modem contains a single transmitter, $\overline{\text{RTS}}$ and $\overline{\text{BRTS}}$ should not be asserted simultaneously. $\overline{\text{BRTS}}$ is meaningful only when a 202 or V.23 mode is selected by MC_0-MC_4. In all other modes, it is ignored.

For the V.23 modes and the 202 150bps (or 75bps) back channel mode, the frequency appearing at TC is determined by a Mark or Space at BTD. For the 202 5bps back channel mode, a frequency of 387 Hz appears at TC when $\overline{\text{BRTS}}$ is LOW and BTD is HIGH. No energy (0.0 Volts) appears at TC when $\overline{\text{BRTS}}$ is HIGH. BTD should be held HIGH in this mode. $\overline{\text{BRTS}}$ then, is equivalent to the transmitted data. $\overline{\text{BRTS}}$ is the Secondary Request-to-Send for 202 S/T modems, or the Supervisory Transmitted Data for 202 C/D modems.

BTD Back Transmitted Data (Input)

This line is equivalent to TD for the main channel, except that it applies only to the back channel. BTD is meaningful only when a 202 or V.23 mode is selected by MC_0-MC_4. For 202 5bps back channel transmission of On/Off keying, BTD should be set HIGH.

$\overline{\text{CTS}}$ Clear To Send (Output)

This output goes LOW at the end of a delay (t_{RCON}) initiated when $\overline{\text{RTS}}$ goes LOW. Actual data to be transmitted should not be presented to TD until a LOW is indicated on $\overline{\text{CTS}}$. This gives the receiving modem (on the other end of the phone line) enough time to recognize a valid carrier signal before data is transmitted. Normally the user should force TD HIGH whenver $\overline{\text{CTS}}$ is HIGH so a Mark will be sent during the t_{RCON} time. $\overline{\text{CTS}}$ goes HIGH at the end of a delay initiated when $\overline{\text{RTS}}$ goes HIGH (t_{RCOFF}). $\overline{\text{CTS}}$ will never be LOW when $\overline{\text{DTR}}$ is HIGH.

$\overline{\text{RTS}}$ Request To Send (Input)

A LOW on this input instructs the modem to enter transmit mode. This input must remain LOW for the duration of data transmission. This signal has no effect if $\overline{\text{DTR}}$ is HIGH (disabled). A HIGH level on this input turns off the transmitter.

11

In the Call Mode, $\overline{RTS}$ also controls the transmitter. When $\overline{RTS}$ is LOW, the tone specified by the MC pins will be transmitted. A HIGH level will turn off the tone. During Answer Tone Detection and Call Progress Tone Detection, $\overline{RTS}$ should be HIGH.

TC   Transmitted Carrier (Output, Non-TTL-Compatible)

This analog output is the modulated carrier to be sent over the phone line. Its frequency changes according to the data at TD or BTD.

TD   Transmitted Data (Input)

Data bits to be transmitted are presented to this input serially; HIGH (Mark) corresponds to logic 1 and LOW (Space) corresponds to logic 0. This input determines which frequency to appear at any instant at TC (See Table 3). No signal appears at TC unless $\overline{DTR}$ is LOW and $\overline{RTS}$ is LOW.

RECEIVER I/O

$\overline{BCD}$ $\overline{Back\ Carrier\ Detect}$ (Output)

This line is equivalent to $\overline{CD}$ for the main channel, except that it applies only to the back channel. $\overline{BCD}$ is meaningful only when a 202 or V.23 mode is selected by MC_0-MC_4. For the V.23 or 202 150bps (or 75bps) back channel modes, $\overline{BCD}$ changes to LOW when either the Mark or Space frequency appears with sufficient level at RC.

For the 202 5bps back channel mode, $\overline{BCD}$ changes to LOW in response to a 387 Hz tone of sufficient level at RC. In this case $\overline{BCD}$ is equivalent to the signal, Secondary Received Line Signal Detector, for 202 S/T modems, or Supervisory Received Data for 202 C/D modems.

BRD   Back Received Data (Output)

This line is equivalent to RD for the main channel, except that it applies only to the back channel. BRD is meaningful only for the V.23 or the 202 back channel modes. Under the following conditions this output is clamped HIGH:

1. V.21/103 modes
2. $\overline{BCD}$ HIGH
3. $\overline{DTR}$ HIGH
4. $\overline{BRTS}$ LOW and $\overline{RTS}$ HIGH in V.23 or 202 150 bps modes only
5. During Autoanswer sequence.

12

$\overline{\text{CD}}$ $\overline{\text{Carrier Detect}}$ (Output)

A LOW on this output indicates that a valid carrier signal is present at the receiver and has been present for at least the time t_{CDON}. A HIGH on this output signifies that no valid carrier is being received and has not been received for at least the time t_{CDOFF}. In the Data Mode, Carrier Detect looks for energy in the receive bandwidth. A carrier is considered valid when the signal level at RC is above a threshold limit V_{CDON}, and absent when the level is below V_{CDOFF}.

In the Call Mode, a $\overline{\text{CD}}$ LOW output indicates a valid answer tone or call progress tone has been detected above the limit V_{CDCON}. A $\overline{\text{CD}}$ HIGH output indicates there is no energy above the V_{CDCOFF}.

RC Received Carrier (Input, Non-TTL-Compatible)

This input is the analog signal received from the phone line. The modem extracts the information contained in this modulated carrier and converts it into a serial data stream at RD or BRD.

RD Received Data (Output)

Data bits demodulated from RC are available serially at this output; HIGH (Mark) indicates logic 1 and LOW (Space) indicates logic 0. Under the following conditions, this output is clamped HIGH because the data may be invalid:

1. When $\overline{\text{CD}}$ is HIGH
2. During the internal squelch delay at half-duplex line turn-around (202 and V.23 modes only)
3. During soft carrier turn-off at half-duplex line turn-around (202 and V.23 soft turn-off modes only)
4. When $\overline{\text{DTR}}$ is HIGH
5. When $\overline{\text{RTS}}$ is LOW and $\overline{\text{BRTS}}$ is HIGH in 202 and V.23 modes only
6. During Autoanswer sequence.

MISCELLANEOUS

AGND Analog Ground

CAP1, CAP2   (Non-TTL-Compatible)

These two pins are connection points for the external
series capacitor-resistor required for proper operation of
the on-chip analog-to-digital converter.

Recommended values are: C = 2000 pF $\pm$10%
             R = 910 ohm $\pm$10%

DGND   Digital Ground

$\overline{\text{RESET}}$ (Non-TTL-Compatible)
This input signal is for a reset circuit which operates in
either of two modes (refer to Figures 15a and 15b). The
Am79101 should be reset upon initial application of
power.

VBB   -5 Volt Power Supply

VCC   +5 Volt Power Supply

$XTAL_1$, $XTAL_2$ (Non-TTL-Compatible)

Master timing of the modem is provided by either a crystal
connected to these two pins or an external clock inserted
into $XTAL_1$. The value of the crystal or the external
clock frequency must be 2.4576 MHz $\pm$.01%.

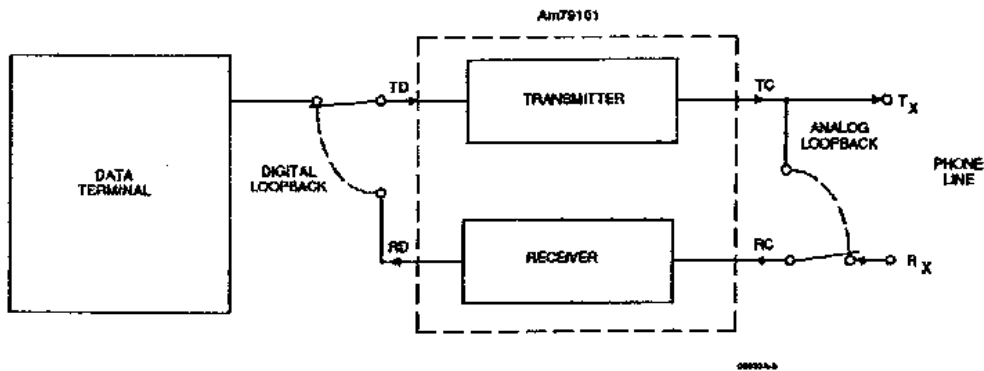

Figure 1. Loopback Configurations

FUNCTIONAL DESCRIPTION

The modem consists of three main sections shown in the Am79101 block diagram - Transmitter, Receiver, and Interface Control.

Transmitter (Modulator)

In the Data Mode, the transmitter, shown in Figure 2, receives binary digital data from a source such as a UART and converts the data to an analog signal using Frequency Shift Keying (FSK) modulation. This analog signal is applied to the phone line through a DAA or an acoustic coupler. FSK is a modulation technique which encodes one bit per baud. A logic 1 applied to the TRANSMITTED DATA (TD) input causes a sine wave at a given frequency to appear at the analog TRANSMITTED CARRIER (TC) output. A logic 0 applied to TD causes a sine wave of a different frequency to appear at TC. As the data at TD switches between logic 1 and 0, TC switches between the two frequencies. In the Am79101 this switching between frequencies is phase continuous. The frequencies themselves are digitally synthesized sine functions.

The frequencies for each modem configuration available in the Am79101 are listed in Table 3.

The process of switching between two frequencies (as in FSK) generates energy at many more frequencies than the two used in the modulation. All the transmitted information can be recovered from a frequency band B Hz wide, where B is the bit rate or maximum rate of change of the digital data at TD. This band is centered about a frequency, f_C,

where $f_C = (f_1 + f_2)/2$
(f_1 = lower of two FSK frequencies)
(f_2 = higher of two FSK frequencies)

18

In addition to this primary information band, there are side bands containing redundant information. It is desirable to attenuate these bands for two reasons:

1.   The phone companies have specifications on the amount of energy allowed in certain frequency bands on the line.

2.   If two independent information channels are present simultaneously on the line (e.g., 300 bps full-duplex or 1200 bps half-duplex with back channel), the redundant transmitter components may fall in the frequency band of the local receiver channel and interfere with detection. In the Am79101 these redundant and undesirable components are attenuated by digital bandpass filters.

Following the digital bandpass filters, the filtered FSK signal is converted to an analog signal by an on-chip Digital-to-Analog Converter (DAC) operating at a high sampling rate. This analog FSK signal is made smooth by a simple on-chip analog low-pass filter.

In the Call Mode, the sine synthesizer generates the DTMF or answer tones as specified by the MC inputs. These tones are then processed like the FSK signal and eventually appear at TC. Table 4 shows the DTMF tone combinations.

Receiver (Demodulator)

A simplified block diagram of the Am79101 FSK receiver is shown in Figure 3. Data transmitted from a remote-site modem over the phone line is a FSK-modulated analog carrier. This carrier is applied to the RECEIVED CARRIER (RC) pin via a DAA or an acoustic coupler. The first stage of the demodulator is a simple on-chip analog low-pass anti-alias filter. The output of this is converted into digital form and filtered by digital bandpass filters to improve the signal-to-noise ratio and reject other independent channel frequencies associated with the phone line in the case of full-duplex configuration. In the Data Mode, the bandpass-filtered output is digitally demodulated to recover the binary data to appear at the RECEIVED DATA (RD) pin. A Carrier Detect signal ($\overline{CD}$) is also digitally extracted from the received line carrier to indicate valid data.
In the Call Mode, the MC inputs select the proper digital bandpass filters to detect answer tones or call progress tones at RC. Presence of a valid tone will be indicated by $\overline{CD}$.

The on-chip hybrid provides the analog interface which communicates TC and RC directly over two wires to and from the telephone line via a DAA.

19
Figure 2. Transmitter Block Diagram

Figure 3. Receiver Block Diagram

Interface Control

This section controls the handshaking between the modem and the local terminal. It consists primarily of delay-generation counters, two state machines for controlling transmission and reception, and mode-control-decode logic. Proper transmit frequencies and transmit/receive filters are selected according to the specified modem type or function in the Data or Call Mode. Inputs to and outputs from this section are as follows:

DATA/$\overline{\text{CALL}}$
$\overline{\text{MC}_0}$-$\overline{\text{MC}_4}$
DATA TERMINAL READY
REQUEST TO SEND (Main and Back)
CLEAR TO SEND (Main and Back)
CARRIER DETECT (Main and Back)
RESET

Internal logic clamps the handshake signals to different levels under certain conditions (e.g., initial conditions).

When Bell 103/113 and V.21 modem configurations are selected, the back channel signals are non-functional.

Figures 8a through 9 depict the sequencing of the two state machines. State machine 1 implements main or back channel transmission. State machine 2 implements reception on main or back channel. Table 5 lists the timing parameters, and Figures 10 through 13 show the handshake timing diagrams for the various modem modes.

The state machine powers-on to the state labeled INITIAL CONDITIONS. Handshake signals are set to or assumed to be the levels listed in Table 2. The machine then waits for DATA TERMINAL READY ($\overline{DTR}$) to go LOW. Whenever $\overline{DTR}$ is changed from LOW to HIGH, each state machine and external signals return to the initial conditions within 25 microseconds. After $\overline{DTR}$ is set LOW, the Am79101 becomes operational as a modem and the state machines proceed as depicted in the flowcharts.

The definitions of the terms full-duplex and half-duplex used in these flowcharts are depicted in Figures 4 and 5. Full-duplex applies to all 103/113 and V.21 modes. Half-duplex applies to 202 and V.23, both main and back channels.

Full-Duplex: Data can be transmitted and received simultaneously at 300 bps. Two independent 300 Hz channels are frequency multiplexed into the 3000 Hz bandwidth of the phone line. The Am79101 configurations for the Bell 103/113 and CCITT V.21 can be operated full-duplex.

Half-Duplex: In half-duplex with back channel, the Am79101 may transmit at 1200/600 bps and receive at 5/75/150 bps. Alternately it may transmit at 5/75/150 bps and receive at 1200/600 bps. Examples are Bell 202 and CCITT V.23.

Table 2. Initial Conditions

Data/$\overline{Call}$ (DA/$\overline{CA}$)	HIGH (Data)
Data Terminal Ready ($\overline{DTR}$)	HIGH
Request-to-Send ($\overline{RTS}$)	HIGH
Clear-to-Send ($\overline{CTS}$)	HIGH
Transmitted Data (TD)	Ignored
Back Channel Request-to-Send ($\overline{BRTS}$)	HIGH
Back Channel Clear-to-Send ($\overline{BCTS}$)	HIGH
Back Channel Transmitted Data (BTD)	Ignored
Carrier Detect ($\overline{CD}$)	HIGH
Received Data (RD)	HIGH
Back Channel Carrier Detect ($\overline{BCD}$)	HIGH
Back Channel Received Data (BRD)	HIGH

   ** No 387 Hz at RC: $\overline{\text{BCD}}$ HIGH.

Call Establishment

The Am79101 supports Autodial and Autoanswer with the following features:

Call Progress Tone Detection (CPTD)
Dual Tone Multi-Frequency (DTMF) Tone Generation
Answer Tone Detection (ATD)
Answer Tone Generation (ATG)

First, the Mode Control (MC_0-MC_4) pins are used to set up the modem mode. Next, the Call Mode is entered by setting DA/$\overline{CA}$=LOW (see pin description). $\overline{DTR}$ is then set LOW once at the beginning of the Autodial or Autoanswer sequence. $\overline{RTS}$ remains HIGH except when tones are required to be transmitted. Now the MC pins can be used to select the above Autodial/Autoanswer features, as defined in Table 1b.

Autodial begins by using the CPTD function to detect the proper dial tone from the central office. The DTMF digit to be dialed is then input to the MC pins and the transmitter generates the corresponding DTMF tones at the TC pin. After the last digit is sent, CPTD is used again to detect the ringback signal. Following the detection of ringback, the ATD feature can be used to detect the answer tone from the called modem. Following detection of the correct answer tone, data transfer can now begin. Figures 6a and 6b show the Autodial flowchart and timings.

As a called modem, the Am79101 will be placed in the Call Mode by the external microprocessor which receives a ring indication signal from the DAA. Autoanswer begins by using ATG. Figures 7a and 7b show the Autoanswer flowchart and timings.

Call Progress Tone Detection (CPTD)

The CPTD filter passes call progress tones from all the major Post Telephone and Telegraphs (PTTs). The cadences (temporal patterns) of $\overline{CD}$ will identify the following signals:

        Primary Dial Tone
        Secondary Dial Tone
        Ringback Signal
        Network Busy Signal
        Busy Signal

Each country's PTT may have different requirements for the cadences of these call progress tones.

Dual Tone Multi-Frequency (DTMF) Tone Generation

The Am79101 transmitter can generate the basic 3 x 4 matrix, as shown in Table 4. According to the Bell specifications, the minimum duration for the DTMF digit is 50 ms. The minimum interdigit interval (silence) is 45 ms. The minimum time from the beginning of one DTMF digit to the next is 100 ms. It is common practice to extend the DTMF digit duration to insure detection by the central office.

Once in the Call Mode, $\overline{RTS}$ controls the duration of the DTMF tone. With $\overline{DTR}$=LOW and the desired digit applied to the MC pins, setting $\overline{RTS}$=LOW will generate the DTMF tone at TC until

24

$\overline{\text{RTS}}$ is set HIGH. The user has complete control of the DTMF
tone duration and the interdigit interval. Inputs to the MC
pins should be changed while $\overline{\text{RTS}}$ is HIGH and $\overline{\text{DTR}}$ is LOW.
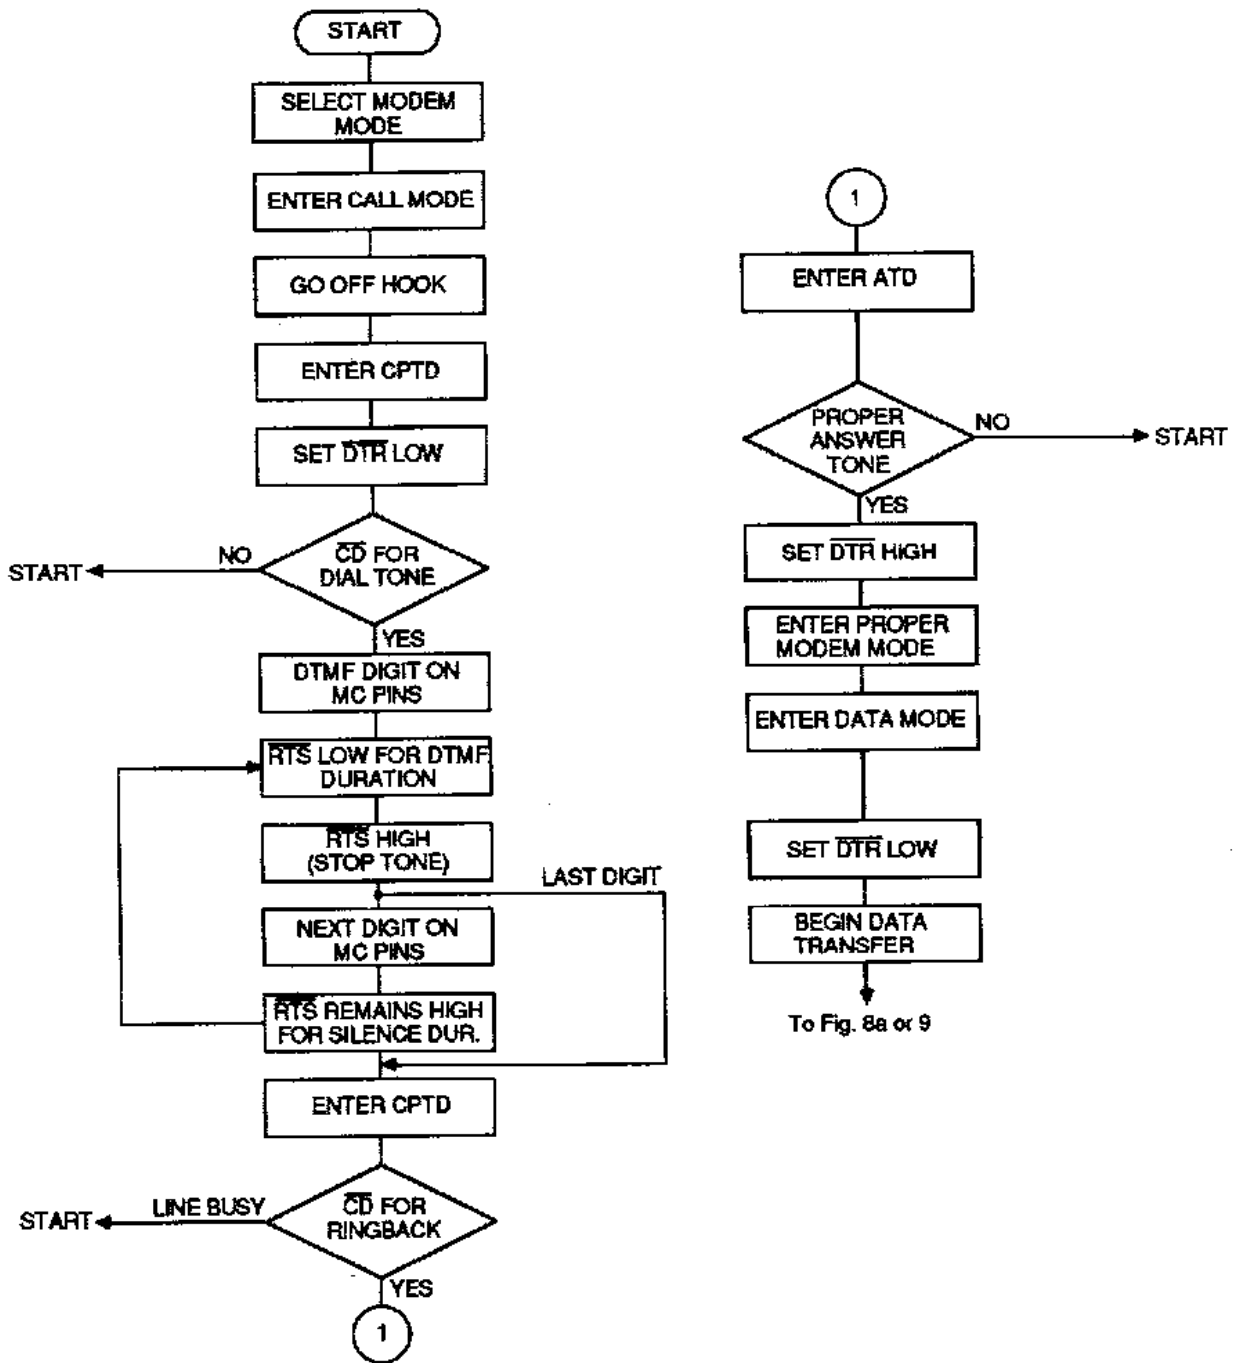

Answer Tone Detection (ATD)

The Am79101 receiver can detect answer tones for the Bell 103,
202, and CCITT V.21/V.23 modes. $\overline{\text{CD}}$=LOW indicates the presence
of a valid answer tone. RD distinguishes between the three
answer tones as shown below. This feature allows mode matching
with the remote modem. In the CCITT V.21/V.23 modes, X at RD
indicates toggling between HIGH and LOW.

Modem Mode	Answer Tone Frequency (Hz)	$\overline{\text{CD}}$	RD
Bell 103	2225	LOW	HIGH
Bell 202	2025	LOW	LOW
CCITT V.21/V.23	2100	LOW	X

The Carrier Detect Call thresholds (V_{CDCON}, V_{CDCOFF}) for valid
answer tone detection are internally set to be higher than
those in the Data Mode. This eliminates the need for an
external attenuator in the Call Mode to prevent noise from
being decoded as an answer tone.

Answer Tone Generation (ATG)

Answer tones are generated according to the modem mode
selected, as listed in the ATD section. $\overline{\text{RTS}}$=LOW controls the
answer tone duration and $\overline{\text{RTS}}$=HIGH controls the silence
intervals. Silence interval before the answer tone is
required by various governmental agencies for billing delay
purposes.

DATA TRANSMISSION*

Full-Duplex

Following call establishment, full-duplex data transmission can
be started by either the called or calling modem. If the
connection has been established and the modem is looping
through point A in Figure 8a, it no longer matters which is the
called and which is the calling modem. Data transmission is
initiated by setting REQUEST TO SEND (RTS) LOW. At this time
the TRANSMITTED DATA (TD) input will be released and a
modulated carrier can appear at the TRANSMITTED CARRIER
(TC) output. Following a delay, t_{RCON}, CLEAR TO SEND (CTS)
changes to LOW. At this time, data may be transmitted through
TD. It is common protocol for the user to always present a
Mark at TD before RTS is asserted and during the t_{RCON} delay.

Data transmission continues until RTS is set HIGH. Following a
short delay, t_{RCOFF}, CTS changes to HIGH. As soon as RTS goes
HIGH, TD is ignored and TC is set to 0.0 Volts (silence).
After CTS changes to HIGH, the state machine returns to point A
in Figure 8a.

Half-Duplex

When a half-duplex mode is selected (202 or V.23), data
transmission can be either on the main channel at 1200/600 bps
or on the back channel at 5/75/150 bps. In normal half-duplex
operation a single modem is either transmitting on the main and
receiving on the back channel or vice-versa. In the Am79101,
control of the transmitter and receiver filters to the proper
channel is performed by RTS. When RTS is asserted, the
transmitter filters and synthesizer are set to transmit on the
main channel; the receiver filters are set to receive on the
back channel. Therefore, whenever RTS is LOW, BRTS should not
be asserted since the transmitter cannot be used for the back
channel. When RTS is HIGH and a half-duplex mode is selected,
the transmitter filters and synthesizer are set to the back
channel; the receiver filters are set to the main channel. If
RTS and BRTS are asserted simultaneously, RTS will take
precedence. However, if BRTS is asserted before RTS and the
the back channel data transmission sequence has been entered
(Figure 8b), RTS will be ignored until BRTS is set HIGH.

The state machine sequences for main and back channel
transmission differ slightly and are depicted in Figures 8a and
8b. Assume the state machine is idling through point A in
Figure 8a.

* All timing delays are listed in Table 5.

30

Main Channel

This transmission sequence is entered if a 202 or V.23 mode is selected and $\overline{RTS}$ is asserted. Since the receiver is now forced to the back channel the RECEIVED DATA (RD) signal is clamped to a Mark, and the CARRIER DETECT ($\overline{CD}$) signal is clamped HIGH. The TRANSMITTED DATA (TD) input is released and a carrier appears at the TRANSMITTED CARRIER (TC) output which follows the Mark/Space applied to TD. $\overline{RTS}$ going LOW initiates a delay, t_{RCON}, at the end of which the CLEAR TO SEND ($\overline{CTS}$) output goes LOW. When $\overline{CTS}$ goes LOW, data may be transmitted through TD. Data transmission continues until $\overline{RTS}$ is set HIGH. At this time several events are initiated. First a delay, t_{RCOFF}, is initiated at the end of which $\overline{CTS}$ goes HIGH. TD is ignored as soon as $\overline{RTS}$ goes HIGH. If a 202 mode or V.23 soft turn-off mode is selected, a soft turn-off tone appears at TC for a time, t_{STO}, followed by silence (0.0 Volts). For both 202 and V.23 modes, a squelch period, t_{SQ}, is initiated when $\overline{RTS}$ goes HIGH. During this period the $\overline{CD}$ output is clamped HIGH, forcing the RD output to a Mark condition. The squelch period begins as soon as $\overline{RTS}$ goes HIGH and thus overlaps both t_{RCOFF} and t_{STO}. At the end of the squelch period, the state machine returns to the idle loop at point A in Figure 8a.

The reasons for squelch and soft turn-off are as follows:

Soft turn-off: When $\overline{RTS}$ goes HIGH at the end of a message, transients occur which may cause spurious Space signals to be received at the remote modem. During soft turn-off the modem transmits a soft carrier frequency for a period, t_{STO}, after $\overline{RTS}$ goes HIGH. This results in a steady Mark on the RECEIVED DATA (RD) line of the remote modem.

Squelch: The local receiver must be turned off after $\overline{RTS}$ is HIGH, until the start of carrier detect, so that line transients are not demodulated. The process of disabling the receiver after $\overline{RTS}$ goes HIGH is called squelching.

Back Channel

This transmission sequence, shown in Figure 8b, is entered if a 202 or V.23 mode is selected, $\overline{RTS}$ is HIGH, and $\overline{BRTS}$ is asserted. The BACK CARRIER DETECT ($\overline{BCD}$) output is forced HIGH and the BACK RECEIVED DATA (BRD) output is clamped to a Mark. The BACK TRANSMITTED DATA (BTD) input is released and a carrier appears at the TC output which follows the Mark/Space applied to BTD. Setting $\overline{BRTS}$ LOW initiates a delay, t_{BRCON}, at the end of which the BACK CLEAR TO SEND ($\overline{BCTS}$) output goes LOW. When $\overline{BCTS}$ goes LOW data may be transmitted through BTD. Data transmission continues until $\overline{BRTS}$ is set HIGH. BTD is immediately ignored and TC is silenced (set to 0.0 Volts). Following a short delay, t_{BRCOFF}, $\overline{BCTS}$ goes HIGH. The signals $\overline{BCD}$ and BRD are released and the state machine returns to idle at point A of Figure 8a. In 202 5 bps back channel mode, BTD

31

should be tied HIGH. Then $\overline{\text{BRTS}}$ controls the On/Off keying modulation. When $\overline{\text{BRTS}}$ is LOW, a 387 Hz tone appears at TC; when $\overline{\text{BRTS}}$ is HIGH, 0.0 Volts appear at TC.

DATA RECEPTION*

Data reception is controlled by state machine 2 and depicted in Figure 9. At power-on, the machine enters initial conditions and remains there until $\overline{\text{DTR}}$ is set LOW. It then loops until either CARRIER DETECT ($\overline{\text{CD}}$) = LOW or BACK CARRIER DETECT ($\overline{\text{BCD}}$) = LOW occurs.

Full-Duplex

In full-duplex data reception, carrier may appear at any time after the phone connection has been established. Reception is independent of transmission. When the receiver detects a valid carrier for at least the time, t_{CDON}, the output $\overline{\text{CD}}$ goes LOW, and valid data can be obtained at RD. Data is received until the receiver detects loss of carrier for at least the time, t_{CDOFF}. At this time $\overline{\text{CD}}$ goes HIGH and RD is clamped to a Mark. The state machine returns to the idle loop at point E.

Half-Duplex

As discussed in the Data Transmission section, when a half-duplex mode has been selected, $\overline{\text{RTS}}$ controls whether the main channel is transmitting or receiving. The back channel can only do the opposite from the main channel. If $\overline{\text{RTS}}$ is HIGH, $\overline{\text{CD}}$ may be activated and the data reception sequence is identical to that discussed above for full-duplex reception. As long as $\overline{\text{RTS}}$ remains HIGH, $\overline{\text{BCD}}$ will never be activated. If $\overline{\text{RTS}}$ is LOW, then $\overline{\text{CD}}$ will never be activated. Instead, the receiver will look for a valid carrier in the back channel frequency band. If a valid carrier exists for at least the time, t_{BCDON}, $\overline{\text{BCD}}$ changes to LOW, and valid data can be obtained at BRD. Data is received until the receiver detects loss of back channel received signal for at least the time, t_{BCDOFF}. At this time, $\overline{\text{BCD}}$ goes HIGH. BRD is clamped to a Mark if V.23 mode or 202 150 bps back channel mode is selected. For 202 5 bps back channel mode, $\overline{\text{BCD}}$ represents the received data. BRD can be ignored. The state machine returns to the idle loop at point E.

LOOPBACK

Eleven modes exist to allow both analog and digital loopback for each modem specification met by the Am79101. When a loopback mode is selected, the signal processing (filters, etc.) for both the transmitter and receiver is set to process

* All timing delays are listed in Table 5.

the same channel or frequency band. This allows the analog
output, TC, and the analog input, RC, to be connected
externally for local analog loopback. Alternately the digital
data signals, TD and RD or BTD and BRD, can be connected
externally, allowing a remote modem to test the local modem
with its digital data signals looped back.

When a loopback mode is selected, the state machine sequences
are altered slightly. If a half-duplex loopback mode is
selected (202 or V.23), the local $\overline{CD}/\overline{BCD}$ is not forced HIGH
when $\overline{RTS}/\overline{BRTS}$ is asserted.

42

CLOCK GENERATION

Master timing of the modem is provided by either a crystal connected to the $XTAL_1$ and $XTAL_2$ pins or an external clock applied to $XTAL_1$.

Crystal

When a crystal is used it should be connected as shown in Figure 14a. The crystal should be a parallel resonance type, and its value must be 2.4576 MHz $\pm$.01%. A list of crystal suppliers is shown below.
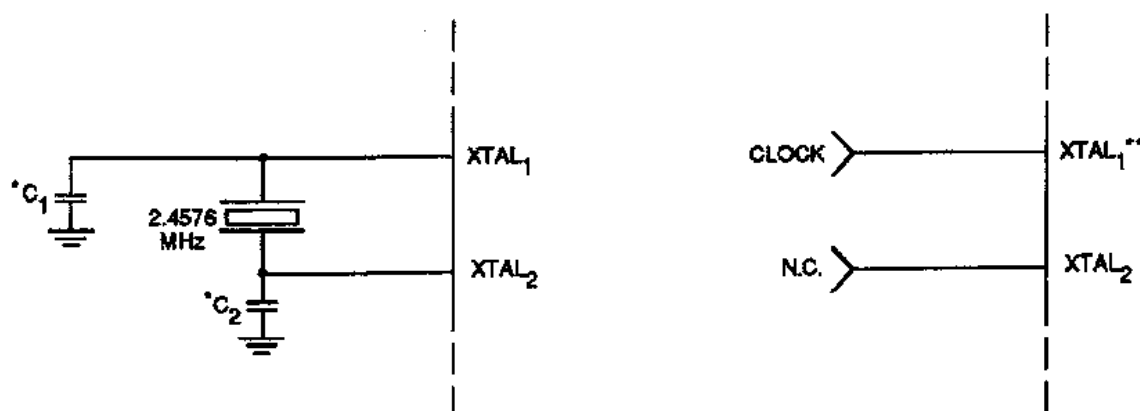

External Clock

This clock signal could be derived from one of several crystal-driven baud rate generators. It should be connected to $XTAL_1$ and $XTAL_2$ must be left floating. The timing parameters required of this clock are shown in Figure 14b and the values are listed in Table 6.

Crystal Information (f=2.4576 MHz)

Manufacturer	P/N	C_1	C_2
M-Tron	MP-2	10 pF	20 pF
Monitor Products	MM-33	10 pF	20 pF

Note: Rise time of V_{CC} must be greater than 5 ms to insure proper crystal oscillator start-up.

* Capacitor values vary with different crystal manufacturers.
** The input impedance of this pin appears as 5 to 10 pF to ground in parallel with at least 1 Megohm.

Figure 14a. Clock Generation

09633A-19

Figure 14b. External Clock

Table 6. Clock Parameters

Symbol	Parameters	Min	Typ	Max	Units
t_{CY}	Clock Period	406.86	406.9	406.94	ns
t_{CH}	Clock High Time	165			ns
t_{CL}	Clock Low Time	165			ns
t_{CR}	Clock Rise Time			20	ns
t_{CF}	Clock Fall Time			20	ns

RESET MODES

Automatic Power-On Reset--Figure 15a suggests a circuit to initiate the internal reset sequence automatically whenever V_{CC} is applied. V_{CC} rise time should be faster than one half the RC time constant. The Am79101 contains a diode to discharge the capacitor when V_{CC} = 0 V.
Figure 15a. Automatic Reset

$\overline{\text{RESET}}$ Input--The Am79101 can be forced into the internal reset
sequence by setting $\overline{\text{RESET}}$ LOW for at least one clock period.

Note that V_{CC} must be at least +3.5 V for proper reset
operation. Between repetitive reset pulses, $\overline{\text{RESET}}$ must be HIGH
for at least 1 us, as shown in Figure 15b.

Figure 15b. Reset Timing Diagrams

Upon device initialization or mode change $\overline{\text{DTR}}$ must be brought
HIGH for a time t_{MSU} >100 microseconds, as shown in Figure 16.

Figure 16. Mode Setup

POWER SUPPLY

For maximum performance, power supply bypassing should be used.
VCC should be decoupled to DGND and VBB to AGND as shown in
Figure 17. The 0.01 uF ceramic disc capacitors should be
mounted as physically close to the pins as possible.

45

09833A-31

Figure 17. Power-Supply Connections

ABSOLUTE MAXIMUM RATINGS

Storage Temperature	-65 to $+125^\circ$C
Ambient Temperature with Power Applied	
Commercial (C) Devices	0 to $+ 70^\circ$C
Industrial (I) Devices	-40 to $+ 85^\circ$C
Extended (E) Devices	-55 to $+125^\circ$C
V_{CC} with Respect to DGND	$+6$ V / $-$ .4 V
V_{BB} with Respect to DGND	-6 V / $+$ .4 V
All Signal Voltages with Respect to DGND	$+ 5$ V

Stresses above those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent device failure. Functionality at or above these limits is not implied. Exposure to absolutely maximum ratings for extended periods may affect device reliability.

Operating Ranges

Positive Supply Voltage (V_{CC})	$+4.75$ to $+ 5.25$ V
Negative Supply Voltage (V_{BB})	-4.75 to $- 5.25$ V
Commercial (C) Devices	0 to $+ 70^\circ$C
Industrial (I) Devices	-40 to $+ 85^\circ$C
Extended (E) Devices	-55 to $+125^\circ$C

Operating ranges define those limits over which the functionality of the device is guaranteed.

FREQUENCY (kHz)

Figure 19.   Out-of-Band Transmitter Energy**

APPLICATIONS

An intelligent Autodial, Autoanswer FSK modem can be easily
built with the Am79101. Figures 20 and 21 show implementations
of full-duplex and half-duplex modes.

For the full-duplex 103/V.21 modes, a single baud rate (300
bps) is used. With its on-chip UART, the single-chip
microcontroller Am8051 provides a simple solution. The
Am79101's RS-232C signals and setup controls are connected to
the Am8051 as shown in Figure 20. MC_4 conveniently controls
the on-hook relay in the DAA circuit. $MC_4=0$ activates off-hook
and $MC_4=1$ keeps on-hook during analog loopback for local
testing. If DTMF dialing is not permitted on a particular
telephone network, the relay contact can be rapidly made and
broken for pulse dialing.

Automatic answering of incoming calls is serviced like an
interrupt routine by the Am8051. Upon ringing, the DAA
interrupts the Am8051, which then places the relay off-hook and
the Am79101 in the Call Mode to generate the answer tone.
After the call is established or answered, the Am8051 has
complete control to start data transfer.

52

For the half-duplex 202/V.23 modes, two different baud rates
(1200 bps and 75/150 bps) are used for the main and back
channels. A dual-UART system is required. Figure 21 shows an
implementation with the Am8051 and the dual-channel Serial
Communication Controller AmZ8530. The AmZ8530 can also be used
in other CPUs, such as Z80, 8080, 6800 and 68000.

The internal hybrid of the Am79101 performs the 4-to-2 wire
conversion to simplify the user interface to the switched
telephone network. The analog signals TC and RC are coupled
directly into the DAA circuit, as shown in Figure 22.
For additional information, refer to AMD's 1987 Modem Technical
Manual (PID# 09560A).
