

## **2.5MHz 4, 8, 10 & 12 Channel Rail-to-Rail Buffers**

**élantec**

The EL5127, EL5227, EL5327, and EL5427 are low power, high voltage rail-to-rail input/output buffers

designed for use in reference voltage buffering applications in small LCD displays. They are available in quad (EL5127), octal (EL5227), 10-channel (EL5327), and 12-channel (EL5427) topologies. All buffers feature a -3dB bandwidth of 2.5MHz and operate from just 133 $\mu$ A per buffer. This family also features a continuous output drive capability of 30mA (sink and source).

The quad channel EL5127 is available in the 10-pin MSOP package. The 8-channel EL5227 is available in both the 20-pin TSSOP and 24-pin QFN packages, the 10-channel EL5327 in the 24-pin TSSOP and 24-pin QFN packages, and the 12-channel EL5427 in the 28-pin TSSOP and 32-pin QFN packages. All buffers are specified for operation over the full -40°C to +85°C temperature range.

## **Features**

- 2.5MHz -3dB bandwidth
- Supply voltage = 4.5V to 16.5V
- Low supply current (per buffer) = 133 $\mu$ A
- High slew rate = 2.2V/ $\mu$ s
- Rail-to-rail input/output swing
- Ultra-small packages

## **Applications**

- TFT-LCD drive circuits
- Electronic games
- Touch-screen displays
- Personal communication devices
- Personal digital assistants (PDAs)
- Portable instrumentation

## Applications Information

### Product Description

The EL5127, EL5227, EL5327, and EL5427 unity gain buffers are fabricated using a high voltage CMOS process. It exhibits rail-to-rail input and output capability and has low power consumption (120µA per buffer). These features make the EL5127, EL5227, EL5327, and EL5427 ideal for a wide range of general-purpose applications. When driving a load of 10kΩ and 12pF, the EL5127, EL5227, EL5327, and EL5427 have a -3dB bandwidth of 2.5MHz and exhibits 2.2V/µs slew rate.

### Operating Voltage, Input, and Output

The EL5127, EL5227, EL5327, and EL5427 are specified with a single nominal supply voltage from 5V to 15V or a split supply with its total range from 5V to 15V. Correct operation is guaranteed for a supply range of 4.5V to 16.5V. Most EL5127, EL5227, EL5327, and EL5427 specifications are stable over both the full supply range and operating

temperatures of -40°C to +85°C. Parameter variations with operating voltage and/or temperature are shown in the typical performance curves.

The output swings of the EL5127, EL5227, EL5327, and EL5427 typically extend to within 80mV of positive and negative supply rails with load currents of 5mA. Decreasing load currents will extend the output voltage range even closer to the supply rails. Figure 22 shows the input and output waveforms for the device. Operation is from ±5V supply with a 10kΩ load connected to GND. The input is a 10V<sub>P-P</sub> sinusoid. The output voltage is approximately 9.985V<sub>P-P</sub>.

FIGURE 22. OPERATION WITH RAIL-TO-RAIL INPUT AND OUTPUT

**Short Circuit Current Limit**

The EL5127, EL5227, EL5327, and EL5427 will limit the short circuit current to ±120mA if the output is directly shorted to the positive or the negative supply. If an output is shorted indefinitely, the power dissipation could easily increase such that the device may be damaged. Maximum reliability is maintained if the output continuous current never exceeds ±30mA. This limit is set by the design of the internal metal interconnects.

**Output Phase Reversal**

The EL5127, EL5227, EL5327, and EL5427 are immune to phase reversal as long as the input voltage is limited from  $V_S - 0.5V$  to  $V_S + 0.5V$ . Figure 23 shows a photo of the output of the device with the input voltage driven beyond the supply rails. Although the device's output will not change phase, the input's overvoltage should be avoided. If an input voltage exceeds supply voltage by more than 0.6V, electrostatic protection diodes placed in the input stage of the device begin to conduct and overvoltage damage could occur.

FIGURE 23. OPERATION WITH BEYOND-THE-RAILS INPUT

**Power Dissipation**

With the high-output drive capability of the EL5127, EL5227, EL5327, and EL5427 buffer, it is possible to exceed the 125°C “absolute-maximum junction temperature” under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the

application to determine if load conditions need to be modified for the buffer to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to:

$$P_{DMAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}}$$

where:

$T_{JMAX}$  = Maximum junction temperature

$T_{AMAX}$  = Maximum ambient temperature

$\theta_{JA}$  = Thermal resistance of the package

$P_{DMAX}$  = Maximum power dissipation in the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the loads, or:

$$P_{DMAX} = \sum i [V_S \times I_{SMAX} + (V_S + V_{OUT}^i) \times I_{LOAD}^i]$$

when sourcing, and:

$$P_{DMAX} = \sum i [V_S \times I_{SMAX} + (V_{OUT}^i - V_S) \times I_{LOAD}^i]$$

when sinking.

where:

$i = 1$  to Total number of buffers

$V_S$  = Total supply voltage

$I_{SMAX}$  = Maximum quiescent current per channel

$V_{OUT}^i$  = Maximum output voltage of the application

$I_{LOAD}^i$  = Load current

If we set the two  $P_{DMAX}$  equations equal to each other, we can solve for  $R_{LOAD}^i$  to avoid device overheat. The package power dissipation curves provide a convenient way to see if the device will overheat. The maximum safe power dissipation can be found graphically, based on the package type and the ambient temperature. By using the previous equation, it is a simple matter to see if  $P_{DMAX}$  exceeds the device's power derating curves.

**Unused Buffers**

It is recommended that any unused buffer have the input tied to the ground plane.

### **Driving Capacitive Loads**

The EL5127, EL5227, EL5327, and EL5427 can drive a wide range of capacitive loads. As load capacitance increases, however, the -3dB bandwidth of the device will decrease and the peaking increase. The buffers drive 10pF loads in parallel with 10k $\Omega$  with just 1.5dB of peaking, and 100pF with 6.4dB of peaking. If less peaking is desired in these applications, a small series resistor (usually between 5 $\Omega$  and 50 $\Omega$ ) can be placed in series with the output. However, this will obviously reduce the gain slightly. Another method of reducing peaking is to add a “snubber” circuit at the output. A snubber is a shunt load consisting of a resistor in series with a capacitor. Values of 150 $\Omega$  and 10nF are typical. The advantage of a snubber is that it does not draw any DC load current or reduce the gain.

### **Power Supply Bypassing and Printed Circuit Board Layout**

As with any high frequency device, good printed circuit board layout is necessary for optimum performance. Ground plane construction is highly recommended, lead lengths should be as short as possible, and the power supply pins must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the V<sub>S-</sub> pin is connected to ground, a 0.1 $\mu$ F ceramic capacitor should be placed from V<sub>S+</sub> pin to V<sub>S-</sub> pin. A 4.7 $\mu$ F tantalum capacitor should then be connected from V<sub>S+</sub> pin to ground. One 4.7 $\mu$ F capacitor may be used for multiple devices. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used.
