1. General description

The SSL1750 is a Switched Mode Power Supply (SMPS) controller IC, suitable for driving LED applications from 25 W up to 250 W. For LED power requirements below 25 W the SSL152x family and SSL1623PH are the best choice.

The SSL1750 combines a controller for Power Factor Correction (PFC) and a flyback controller. Its high level of integration allows the design of a cost-effective LED power supply with a very low number of external components.

The special built-in green functions provide high efficiency at all power levels. This applies to quasi-resonant operation at high power levels, quasi-resonant operation with valley skipping, as well as to reduced frequency operation at lower power levels. At low power levels, the PFC switches over to burst mode control to maintain high efficiency. In burst mode, soft-start and soft-stop functions are added to eliminate audible noise.

During low power conditions, the flyback controller switches to frequency reduction mode and limits the peak current to 25 % of its maximum value. This will ensure high efficiency at low power while minimizing audible noise from the transformer.

The proprietary high voltage BCD800 process makes direct start-up possible from the rectified universal mains voltage in an effective and green way. A second low voltage Silicon On Insulator (SOI) IC is used for accurate, high speed protection functions and control.

The SSL1750 enables highly efficient and reliable LED drivers with power requirements of up to 250 W to be designed easily and with the minimum number of external components.

2. Features

2.1 Distinctive features

- Integrated PFC and flyback controller
- Universal mains supply operation (70 V to 276 V (AC))
- High level of integration resulting in a very low external component count and a cost effective design

2.2 Green features

■ On-chip start-up current source

2.3 PFC green features

■ Valley/zero voltage switching for minimum switching losses (patented)

- Frequency limitation to reduce switching losses
- Burst mode operation if a low load is detected at the flyback output (patented)

2.4 Flyback green features

- Valley switching for minimum switching losses (patented)
- Frequency reduction with fixed minimum peak current at low power operation to maintain high efficiency at low output power levels

2.5 Protection features

- Safe restart mode for system fault conditions
- Continuous mode protection by means of demagnetization detection for both converters (patented)
- Undervoltage protection (foldback during overload)
- Accurate OverVoltage Protection (OVP) for both converters (adjustable for flyback converter)
- Open control loop protection for both converters
- IC overtemperature protection
- Low and adjustable OverCurrent Protection (OCP) trip level for both converters
- Soft-(re)start for both converters
- Soft-stop PFC to minimize audible noise
- Mains undervoltage protection / brownout protection
- General purpose input for latched protection, e.g. to be used for system OverTemperature Protection (OTP)

3. Applications

The device can be used in all SSL applications that require an efficient and cost-effective LED power supply solution up to 250 W.

Key applications for the SSL1750 are:

- Indoor LED applications (> 25 W):
	- **–** Spot lights
	- **–** Down lights
	- **–** Other SSL consumer/industrial fixtures
- Outdoor LED applications (> 25 W):
	- **–** Street lighting
	- **–** Area lighting (e.g. car parking)
	- **–** Tunnel lighting

6.2 Pin description

7. Functional description

7.1 General control

The SSL1750 contains a controller for a power factor correction circuit as well as a controller for a flyback circuit. The SSL1750 as LED driver can be used as current source to drive LEDs directly, as shown in Figure 3. The SSL1750 can also be used as a typical AC/DC converter to drive multiple DC/DC LED drivers as shown in Figure 4.

7.1.1 Start-up and undervoltage lockout

Initially the capacitor on pin V_{CC} is charged from the high voltage mains via pin HV.

As long as V_{CC} is below V_{trip} , the charge current is low. This protects the IC in case pin V_{CC} is shorted to ground. For a short start-up time the charge current above V_{trip} is increased until V_{CC} reaches V_{th(UVLO)}. If V_{CC} is between V_{th(UVLO)} and V_{startup}, the charge current is low again, ensuring a low duty cycle during fault conditions.

The control logic activates the internal circuitry and switches off the charge current when the voltage on pin V_{CC} passes the V_{startun} level. First, the output on pin LATCH is activated and the soft-start capacitors on the pins PFCSENSE and FBSENSE are charged. When the voltage on pin LATCH exceeds the $V_{en(LATCH)}$ voltage and the soft-start capacitor on pin PFCSENSE is charged, the PFC circuit is activated. The supply current from the pin HV is then switched on again and the PFC circuit charges the C_{bus} capacitor. When the voltage on pin VOSENSE reaches the $V_{start(fb)}$ level, the charge current is switched off and the flyback converter is activated (providing the soft-start capacitor on pin FBSENSE is charged). The output voltage of the flyback converter is then regulated to its nominal output voltage. The IC supply is taken over by the auxiliary winding of the flyback converter. See Figure 5.

When the PFC is started, there is initially no supply takeover from the auxiliary winding. To make a small V_{CC} capacitor possible, the V_{CC} voltage is regulated to the V_{startup} level, as long as the flyback converter has not yet started. Regulation is done by hysteretic control with a limited (high level) charge current. The hysteresis is typically 300 mV.

If during start-up pin LATCH does not reach the $V_{en(LATCH)}$ level before V_{CC} reaches $V_{th(UVLO)}$, its output is deactivated and the charge current is switched on again.

As soon as the flyback converter is started, the voltage on pin FBCTRL is monitored. If the output voltage of the flyback converter does not reach its intended regulation level in a predefined time, the voltage on pin FBCTRL reaches the $V_{\text{to(FBCTR)}}$ level and an error is assumed. The SSL1750 then initiates a safe restart.

When one of the protection functions is activated, both converters stop switching and the V_{CC} voltage drops to $V_{th(UVLO)}$. A latched protection recharges the V_{CC} capacitor via pin HV, but does not restart the converters. For a safe restart protection, the capacitor is recharged via pin HV and the device restarts (see Figure 1).

In the event of an overvoltage protection of the PFC circuit (V_1 on pin VOSENSE > $V_{ovp(VOSENSE)}$), only the PFC controller stops switching until the voltage on pin VOSENSE drops below V_{ovp(VOSENSE)} again. Also, if a mains undervoltage is detected (V_1 on pin VINSENSE < $V_{stop(VINSENSE)}$), only the PFC controller stops switching until V_1 on pin VINSENSE > $V_{\text{start}(V \mid NSE NSE)}$ again.

When the voltage on pin V_{CC} drops below the undervoltage lockout level, both controllers stop switching and reenter the safe restart mode. In the safe restart mode the driver outputs are disabled and pin V_{CC} voltage is recharged via pin HV.

NXP Semiconductors SSL1750

SMPS control IC for LED drivers

7.1.2 Supply management

All internal reference voltages are derived from a temperature compensated and trimmed on-chip band gap circuit. Internal reference currents are derived from a temperature compensated and trimmed on-chip current reference circuit.

7.1.3 Latch input

The pin LATCH is a general purpose input pin, which can be used to switch off both converters. The pin sources a current, $I_{O(LATCH)}$ on the pin LATCH (typical 80 μ A). Switching of both converters is stopped as soon as the voltage on this pin drops below 1.25 V.

At initial start-up switching is inhibited until the voltage on pin LATCH is above 1.35 V (typ). No internal filtering is done on this pin. An internal Zener clamp of 2.7 V (typ) protects this pin from excessive voltages.

7.1.4 Fast latch reset

In a typical application, the mains can be interrupted briefly to reset the latched protection. The PFC bus capacitor, C_{bus} , does not have to discharge for this latched protection to reset.

Typically, the PFC bus capacitor, C_{bus} , has to discharge for the V_{CC} to drop to this reset level. When the latched protection is set, the clamping circuit of the VINSENSE circuit is disabled (see also Section 7.2.8). As soon as the VINSENSE voltage drops below 750 mV (typ) and is then raised to 870 mV (typ), the latched protection is reset.

The latched protection will also be reset by removing both the voltage on pin V_{CC} and on pin HV.

7.1.5 Overtemperature protection (OTP)

An accurate internal temperature protection is provided in the circuit. When the junction temperature exceeds the thermal shutdown temperature, the IC only stops switching. As long as OTP is active, the V_{CC} capacitor is not recharged from the HV mains. The OTP circuit is supplied from pin HV if the V_{CC} supply voltage is not sufficient.

OTP is a latched protection. It can be reset by removing both the voltage on pin V_{CC} and on pin HV or by the fast latch reset function, see Section 7.1.4.

7.2 Power factor correction circuit

The power factor correction circuit operates in quasi-resonant or discontinuous conduction mode with valley switching. The next primary stroke is only started when the previous secondary stroke has ended and the voltage across the PFC MOSFET has reached a minimum value. The voltage on pin PFCAUX is used to detect transformer demagnetization and the minimum voltage across the external PFC MOSFET switch.

7.2.1 t_{on} control

The power factor correction circuit is operated in t_{on} control. The resulting mains harmonic reduction of a typical application is well within the class-D requirements.

7.2.2 Valley switching and demagnetization (pin PFCAUX)

The PFC MOSFET is switched on after the transformer is demagnetized. Internal circuitry connected to pin PFCAUX detects the end of the secondary stroke. It also detects the voltage across the PFC MOSFET. The next stroke is started if the voltage across the PFC MOSFET is at its minimum in order to reduce switching losses and ElectroMagnetic Interference (EMI) (valley switching).

If no demagnetization signal is detected on pin PFCAUX, the controller generates a Zero Current Signal (ZCS), 50 µs (typ) after the last PFC gate signal.

If no valley signal is detected on pin PFCAUX, the controller generates a valley signal 4 µs (typ) after demagnetization was detected.

To protect the internal circuitry, for example during lightning events, it is advisable to add a 5 kΩ series resistor to this pin. To prevent incorrect switching due to external disturbance, the resistor should be placed close to the IC on the printed-circuit board.

For applications with high transformer ringing frequencies (after the secondary stroke), Pin PFCAUX should be connected via a capacitor and a resistor to the auxiliary winding. A diode must then be placed from the ground connection to pin PFCAUX.

7.2.3 Frequency limitation

To optimize the transformer and minimize switching losses, the switching frequency is limited to $f_{\text{sw(PFC)max}}$. If the frequency for quasi-resonant operation is above the $f_{\text{sw(PFC)max}}$ limit, the system switches over to discontinuous conduction mode. Also here, the PFC MOSFET is only switched on at a minimum voltage across the switch (valley switching).

7.2.4 Mains voltage compensation (pin VINSENSE)

The mathematical equation for the transfer function of a power factor corrector contains the square of the mains input voltage. In a typical application this results in a low bandwidth for low mains input voltages, while at high mains input voltages the Mains Harmonic Reduction (MHR) requirements may be hard to meet.

To compensate for the mains input voltage influence, the SSL1750 contains a correction circuit. Via pin VINSENSE the average input voltage is measured and the information is fed to an internal compensation circuit. With this compensation it is possible to keep the regulation loop bandwidth constant over the full mains input range, yielding a fast transient response on load steps, while still complying with class-D MHR requirements.

In a typical application, the bandwidth of the regulation loop is set by a resistor and two capacitors on pin PFCCOMP.

7.2.5 Soft start-up (pin PFCSENSE)

To prevent audible transformer noise at start-up or during hiccup, the transformer peak current, I_{DM} , is increased slowly by the soft-start function. This can be achieved by inserting R_{SS1} and C_{SS1} between pin PFCSENSE and current sense resistor R_{SENSE1} . An internal current source charges the capacitor to $V_{PFCSENSE} = I_{start(soft)PFC} \times R_{SS1}$. The voltage is limited to $V_{\text{start}(soft)PFC}$.

The start level and the time constant of the increasing primary current level can be adjusted externally by changing the values of R_{SS1} and C_{SS1} . See Equation 1.

$$
\tau_{\text{SoftStart}} = 3 \times R_{SSI} \times C_{SSI}
$$

(1)

The charging current $I_{\text{start}(soft)PFC}$ flows as long as the voltage on pin PFCSENSE is below 0.5 V (typ). If the voltage on pin PFCSENSE exceeds 0.5 V, the soft-start current source starts limiting current $I_{start(soft)PEC}$. As soon as the PFC starts switching, the I_{start(soft)PFC} current source is switched off, see Figure 6.

7.2.6 Burst mode control

When the output power of the flyback converter (see Section 7.3) is low, the flyback converter switches over to frequency reduction mode. When frequency reduction mode is entered by the flyback controller, the power factor correction circuit switches to burst mode control.

In burst mode control, switching of the power factor correction circuit is inhibited until the voltage on pin VOSENSE has dropped to $V_{burst(L)}$. Switching then restarts with a soft-start to avoid audible noise (see Section 7.2.5). As soon as the voltage on pin VOSENSE reaches $V_{burst(H)}$ the soft-stop circuit is activated, again to avoid audible noise. During the soft-stop time the output voltage of the power factor correction circuit overshoots, depending on the soft-start resistor and capacitor, R_{SS1} and C_{SS1} on pin PFCSENSE. As the $V_{burst(H)}$ voltage is well below the $V_{reg(VOSENSE)}$ voltage, the PFC output voltage does not reach the normal operation output voltage of the power factor correction circuit in a typical application due to this overshoot.

The burst mode repetition rate is defined by the output power and the value of the bus capacitor, C_{bus}.

During burst mode operation pin PFCCOMP is clamped between a voltage of 2.7 V (typ) and 3.9 V (typ). The lower clamp voltage limits the maximum power that is delivered during burst mode operation and yields a more sinusoidal input current during the burst pulse. The upper clamp voltage ensures that the PFC can return to its normal regulation point in a limited amount of time when returning from burst mode.

As soon as the flyback converter leaves frequency reduction mode, the power factor correction circuit restores normal operation. To prevent continuous on and off switching of the PFC circuit, a small hysteresis has been built in (50 mV (typ) on pin FBCTRL).

7.2.7 Overcurrent protection (pin PFCSENSE)

The maximum peak current is limited cycle-by-cycle by sensing the voltage across an external sense resistor (R_{SENSE1}) on the source of the external MOSFET. The voltage is measured via the pin PFCSENSE.

7.2.8 Mains undervoltage lockout / brownout protection (pin VINSENSE)

To prevent the PFC from operating at very low mains input voltages, the voltage on pin VINSENSE is sensed continuously. As soon as the voltage on this pin drops below the V_{stop(VINSENSE)} level, switching of the PFC is stopped. If the low mains situation continues, the PFC bus voltage eventually drops. The voltage on pin VOSENSE then drops below the $V_{\text{start(fb)}}$ level and the flyback converter is also disabled.

The voltage on pin VINSENSE is clamped to a minimum value, $(V_{start(VINSENSE) - \Delta V_{pu(VINSENSE)}}$, for a fast restart as soon as the mains input voltage is restored after a mains dropout.

7.2.9 Overvoltage protection (pin VOSENSE)

An overvoltage protection circuit has been built in to prevent output overvoltage during load steps and mains transients.

As soon as the voltage on pin VOSENSE exceeds the V_{ovp(VOSENSE)} level, switching of the power factor correction circuit is inhibited. Switching of the PFC recommences as soon as the voltage on VOSENSE voltage drops below the $V_{ovp(VOSENSE)}$ level again.

When the resistor between pin VOSENSE and ground is open, the overvoltage protection is also triggered.

7.2.10 PFC open loop protection (pin VOSENSE)

The power factor correction circuit does not start switching until the voltage on pin VOSENSE is above the $V_{th(ol)(VOSENSE)}$ level. This protects the circuit from open loop and VOSENSE short situations. As pin VOSENSE draws a small input current, switching is also inhibited when the pin is left open.

7.2.11 Driver (pin PFCDRIVER)

The driver circuit to the gate of the power MOSFET has a current sourcing capability of typically 500 mA and a current sink capability of typically 1.2 A. This permits fast turn-on and turn-off of the power MOSFET for efficient operation.

7.3 Flyback controller

The SSL1750 includes a controller for a flyback converter. The flyback converter operates in quasi-resonant or discontinuous conduction mode with valley switching. The auxiliary winding of the flyback transformer provides demagnetization detection and powers the IC after start-up.

7.3.1 Multimode operation

The SSL1750 flyback controller can operate in various modes, see Figure 8.

At high output power the converter switches to quasi-resonant mode. The next converter stroke is started after demagnetization of the transformer current. In quasi-resonant mode switching losses are minimized as the converter only switches on when the voltage across the external MOSFET is at its minimum (valley switching, see also Section 7.3.2).

To prevent high frequency operation at lower loads, the quasi-resonant operation changes to discontinuous mode operation with valley skipping in which the switching frequency is limited for EMI to $f_{sw(fb)(max)}$ (125 kHz typ). Again, the external MOSFET is only switched on when the voltage across the MOSFET is at its minimum.

At very low power and standby levels the frequency is controlled down by a Voltage Controlled Oscillator (VCO). The minimum frequency can be reduced to zero. During frequency reduction mode, the primary peak current is kept at a minimal level of Ipkmax/4 to maintain a high efficiency. (Ipkmax is the maximum primary peak current set by the sense resistor and the maximum sense voltage.) As the primary peak current is low in frequency reduction mode operation $(Ipk = Ibkmax/4)$, no audible noise is noticeable at switching frequencies in the audible range. Valley switching is also active in this mode.

In frequency reduction mode the PFC controller is switched to burst mode operation and the flyback maximum frequency changes linearly with the control voltage on pin FBCTRL (see Figure 9). For stable on-off switching of the PFC burst mode pin FBCTRL has a 50 mV (typ) hysteresis. At no load operation the switching frequency of the flyback can be reduced to (almost) zero.

7.3.2 Valley switching (pin HV)

See Figure 10. A new cycle starts when the external MOSFET is activated. After the on-time (determined by the FBSENSE voltage and the FBCTRL voltage), the MOSFET is switched off and the secondary stroke starts. After the secondary stroke, the drain voltage shows an oscillation with a frequency of approximately, see Equation 2

$$
\frac{1}{(2 \times \pi \times \sqrt{(L_p \times C_d)})} \tag{2}
$$

where L_p is the primary self-inductance of the flyback transformer and C_d is the capacitance on the drain node.

As soon as the internal oscillator voltage is high again and the secondary stroke has ended, the circuit waits for the lowest drain voltage before starting a new primary stroke. Figure 10 shows the drain voltage, valley signal, secondary stroke signal, and the internal oscillator signal.

Valley switching allows high frequency operation as capacitive switching losses are reduced, see Equation 3. High frequency operation makes small and cost-effective magnetics possible.

$$
\left(P = \frac{1}{2} \times C_d \times V^2 \times f\right)
$$

(3)

NXP Semiconductors SSL1750

SMPS control IC for LED drivers

7.3.3 Current mode control (pin FBSENSE)

Current mode control is used for the flyback converter for its good line regulation.

The primary current is sensed by pin FBSENSE across an external resistor and compared with an internal control voltage.The internal control voltage is proportional to the voltage on pin FBCTRL.

The driver output is latched in the logic, preventing multiple switch-on.

7.3.4 Demagnetization (pin FBAUX)

The system is always in quasi-resonant or discontinuous conduction mode. The internal oscillator does not start a new primary stroke until the previous secondary stroke has ended.

Demagnetization features a cycle-by-cycle output short circuit protection by immediately lowering the frequency (longer off-time), thereby reducing the power level.

Demagnetization recognition is suppressed during the first $t_{sup(xfmr_ring)}$ time (2 µs typ). This suppression may be necessary at low output voltages and at start-up and in applications where the transformer has a large leakage inductance.

If pin FBAUX is open-circuit or not connected, a fault condition is assumed and the converter stops operating immediately. Operation restarts as soon as the fault condition is removed.

7.3.5 Flyback control / time-out (pin FBCTRL)

Pin FBCTRL is connected to an internal voltage source of 3.5 V via an internal resistor (typical resistance is 3 kΩ). As soon as the voltage on this pin is above 2.5 V (typ), this connection is disabled. Above 2.5 V the pin is biased with a small current. When the voltage on this pin rises above 4.5 V (typ), a fault is assumed and switching is inhibited.

When a small capacitor is connected to this pin, a time-out function can be created to protect against an open control loop situation (see Figure 12 and Figure 13). The time-out function can be disabled by connecting a resistor (100 kΩ) to ground on pin FBCTRL.

If the pin is shorted to ground, switching of the flyback controller is inhibited.

In normal operating conditions, when the converter is regulating the output, the voltage on pin FBCTRL is between 1.4 V and 2.0 V (typical values) from minimum to maximum output power.

7.3.6 Soft start-up (pin FBSENSE)

To prevent audible transformer noise during start-up, the transformer peak current, I_{DM} is slowly increased by the soft-start function. This can be achieved by inserting a resistor and a capacitor between pin FBSENSE and the current sense resistor.

An internal current source charges the capacitor to $V = I_{start(soft)(fb)} \times R_{SS2}$, with a maximum of approximately 0.5 V.

The start level and the time constant of the increasing primary current level can be adjusted externally by changing the values of R_{SS2} and C_{SS2} . See Equation 4.

$$
\tau_{\text{SoftStart}} = 3 \times R_{SS2} \times C_{SS2} \tag{4}
$$

The soft start current $I_{start(soft)(fb)}$ is switched on as soon as V_{CC} reaches $V_{startup}$. When the voltage on pin VOSENSE reaches the $V_{\text{start(fb)}}$ level and the voltage on pin FBSENSE has reached 0.5 V, the flyback converter starts switching.

The soft-start current flows as long as the voltage on pin FBSENSE is below approximately 0.5 V. If the voltage on pin FBSENSE exceeds 0.5 V, the soft-start current source starts limiting the current. After the flyback converter has started, the soft-start current source is switched off.

7.3.7 Maximum on-time

The flyback controller limits the 'on-time' of the external MOSFET to 25 us (typ). When the 'on-time' is longer than 25 µs, the IC stops switching and enters the safe restart mode.

7.3.8 Overvoltage protection (pin FBAUX)

An output overvoltage protection is implemented in this IC. This works for the SSL1750 by sensing the auxiliary voltage via the current flowing into pin FBAUX during the secondary stroke. The auxiliary winding voltage is a well-defined replica of the output voltage. Voltage spikes are averaged by an internal filter.

If the output voltage exceeds the OVP trip level, an internal counter starts counting subsequent OVP events. The counter has been added to prevent incorrect OVP detection which might occur during ElectroStatic Discharge (ESD) or lightning events. If the output voltage exceeds the OVP trip level a few times and not again in a subsequent cycle, the internal counter counts down at twice the speed it uses when counting up. However, when typically 8 cycles of subsequent OVP events are detected, the IC assumes a true OVP and the OVP circuit switches the power MOSFET off. As the protection is latched, the converter only restarts after the internal latch is reset. In a typical application the mains should be interrupted to reset the internal latch.

The output voltage $V_{ovp(FBAUX)}$ at which the OVP function trips, can be set by the demagnetization resistor, R_{FBAUX} . See Equation 5.

$$
V_{o(ovp)} = \frac{N_s}{N_{aux}} (I_{ovp(FBAUX)} \times R_{FBAUX} + V_{clamp(FBAUX)})
$$
\n(5)

where N_s is the number of secondary turns and N_{aux} is the number of auxiliary turns of the transformer. Current $I_{ovp(FBAUX)}$ is internally trimmed.

The value of R_{FBAUX} can be adjusted to the turns ratio of the transformer, thus making an accurate OVP detection possible.

7.3.9 Overcurrent protection (pin FBSENSE)

The primary peak current in the transformer is measured accurately cycle-by-cycle using the external sense resistor R_{SENSE2} . The OCP circuit limits the voltage on pin FBSENSE to an internal level (see also Section 7.3.3). The OCP detection is suppressed during the leading edge blanking period, t_{leb} , to prevent false triggering caused by switch-on spikes.

7.3.10 Driver (pin FBDRIVER)

The driver circuit to the gate of the external power MOSFET has a current sourcing capability of typically 500 mA and a current sink capability of typically 1.2 A. This permits fast turn-on and turn-off of the power MOSFET for efficient operation.

13.1 Data sheet status

[1] Please consult the most recently issued document before initiating or completing a design.

[2] The term 'short data sheet' is explained in section "Definitions"

The product status of device(s) described in this document may have changed since this document was published and may differ in case of multiple devices. The latest product status information is available on the Internet at URL http://www.nxp.com.

13.2 Definitions

Draft — The document is a draft version only. The content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included herein and shall have no liability for the consequences of use of such information.

Short data sheet — A short data sheet is an extract from a full data sheet with the same product type number(s) and title. A short data sheet is intended for quick reference only and should not be relied upon to contain detailed and full information. For detailed and full information see the relevant full data sheet, which is available on request via the local NXP Semiconductors sales office. In case of any inconsistency or conflict with the short data sheet, the full data sheet shall prevail.

13.3 Disclaimers

General — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in medical, military, aircraft, space or life support equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors accepts no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Limiting values — Stress above one or more limiting values (as defined in the Absolute Maximum Ratings System of IEC 60134) may cause permanent damage to the device. Limiting values are stress ratings only and operation of the device at these or any other conditions above those given in the Characteristics sections of this document is not implied. Exposure to limiting values for extended periods may affect device reliability.

Terms and conditions of sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at http://www.nxp.com/profile/terms, including those pertaining to warranty, intellectual property rights infringement and limitation of liability, unless explicitly otherwise agreed to in writing by NXP Semiconductors. In case of any inconsistency or conflict between information in this document and such terms and conditions, the latter will prevail.

No offer to sell or license — Nothing in this document may be interpreted or construed as an offer to sell products that is open for acceptance or the grant, conveyance or implication of any license under any copyrights, patents or other industrial or intellectual property rights.
