

HD6801S0, HD6801S5 MCU (Microcomputer Unit)

The HD6801S MCU is an 8-bit microcomputer unit which is compatible with the HMCS6800 family of parts. The HD6801S MCU is object code compatible with the HD6800 with improved execution times of key instructions plus several new 16-bit and 8-bit instructions including an 8x8 unsigned multiply with 16-bit result. The HD6801S MCU can operate as a single-chip microcomputer or be expanded to 65k bytes. The HD6801S MCU is TTL compatible and requires one +5.0 volt power supply. The HD6801S MCU has 2k bytes of ROM and 128 bytes of RAM on chip. Serial Communication interface (S.C.I.), and parallel I/O as well as a three function 16-bit timer. Features and Block diagram of the HD6801S include the following:

■ FEATURES

- Expanded HMCS6800 Instruction Set
- 8 x 8 Multiply
- On-Chip Serial Communication Interface (S.C.I.)
- Object Code Compatible With The HD6800 MPU
- 16-Bit Timer
- Single Chip Or Expandable To 65k Bytes
- 2k Bytes Of ROM
- 128 Bytes Of RAM (64 Bytes Retainable On Power Down)
- 29 Parallel I/O Lines And 2 Handshake Control Lines
- Internal Clock/Divided-By-Four Circuitry
- TTL Compatible Inputs And Outputs
- Interrupt Capability
- Compatible with MC6801 and MC6801-1

● SIGNAL DESCRIPTIONS

● VCC and VSS

These two pins are used to supply power and ground to the chip. The voltage supplied will be +5 volts $\pm 5\%$.

● XTAL and EXTERNAL

These connections are for a parallel resonant fundamental crystal, AT cut. Divide-by-4 circuitry is included with the internal clock, so a 4 MHz crystal may be used to run the system at 1 MHz. The divide-by-4 circuitry allows for use of the inexpensive 3.58 MHz Color TV crystal for non-time critical applications. Two 22pF capacitors are needed from the two crystal pins to ground to insure reliable operation. An example of the crystal interface is shown in Fig. 12. EXTERNAL may be driven by an external clock source at a 4 MHz rate to run at 1 MHz with 45% to 55% duty cycle. It is not restricted to 4 MHz, as it will divide by 4 any frequency less than or equal to 5 MHz. XTAL must be grounded if an external clock is used.

Nominal Crystal Parameter

Crystal Item	4 MHz	5 MHz
C_0	7 pF max.	4.7 pF max.
R_s	60 Ω max.	30 Ω typ.

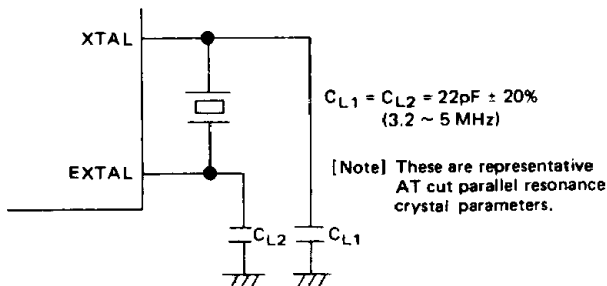

Figure 12 Crystal Interface

● VCC Standby

This pin will supply +5 volts $\pm 5\%$ to the standby RAM on the chip. The first 64 bytes of RAM will be maintained in the power down mode with 8 mA current max. The circuit of figure 13 can be utilized to assure that VCC Standby does not go below V_{SBB} during power down.

To retain information in the RAM during power down the following procedure is necessary:

- 1) Write "0" into the RAM enable bit, RAME. RAME is bit 6 of the RAM Control Register at location \$0014. This disables the standby RAM, thereby protecting it at power down.
- 2) Keep VCC Standby greater than V_{SBB}.

Figure 13 Battery Backup for VCC Standby

● Reset (\overline{RES})

This input is used to reset and start the MCU from a power down condition, resulting from a power failure or an initial startup of the processor. On power up, the reset must be held "Low" for at least 100 ms. When reset during operation, RES must be held "Low" at least 3 clock cycles.

When a "High" level is detected, the MCU does the following:

- 1) All the higher order address lines will be forced "High".
- 2) I/O Port 2 bits 2, 1, and 0 are latched into programmed control bits PC2, PC1 and PC0.
- 3) The last two (\$FFFE, \$FFFF) locations in memory will be used to load the program addressed by the program counter.
- 4) The interrupt mask bit is set. Clear before the CPU can recognize maskable interrupts.

● Enable (E)

This supplies the external clock for the rest of the system when the internal oscillator is used. It is a single phase, TTL compatible clock, and will be the divide-by-4 result of the crystal oscillator frequency. It will drive one TTL load and 90 pF capacitance.

● Non-Maskable Interrupt (NMI)

A low-going edge on this input requests that a non-maskable-interrupt sequence be generated within the processor. As with interrupt Request signal, the processor will complete the current instruction that is being executed before it recognizes the NMI signal. The interrupt mask bit in the Condition Code Register has no effect on NMI.

In response to an \overline{NMI} interrupt, the Index Register, Program Counter, Accumulators, and Condition Code Register are stored on the stack. At the end of the sequence, a 16-bit address will be loaded that points to a vectoring address located in memory locations \$FFFC and \$FFFD. An address loaded at these locations causes the CPU to branch to a non-maskable interrupt service routine in memory.

A 3.3 k Ω external resistor to VCC should be used for wire-OR and optimum control of interrupts.

Inputs $\overline{IRQ_1}$ and \overline{NMI} are hardware interrupt lines that are sampled during E and will start the interrupt routine on the \overline{E} following the completion of an instruction.

● Interrupt Request ($\overline{IRQ_1}$)

This level sensitive input requests that an interrupt sequence be generated within the machine. The processor will complete the current instruction before it recognizes the request. At that time, if the interrupt mask bit in the Condition Code Register is not set, the machine will begin an interrupt sequence. The Index Register, Program Counter, Accumulators, and Condition Code Register are stored on the stack. Next the CPU will respond to the interrupt request by setting the interrupt mask bit "High" so that no further maskable interrupts may occur. At the end of the cycle, a 16-bit address will be loaded that points to a vectoring address which is located in memory locations \$FFF8 and \$FFF9. An address loaded at these locations causes the CPU to branch to an interrupt routine in memory.

The $\overline{IRQ_1}$ requires a 3.3 k Ω external resistor to VCC which should be used for wire-OR and optimum control of interrupts. Internal Interrupts will use an internal interrupt line ($\overline{IRQ_2}$). This interrupt will operate the same as $\overline{IRQ_1}$, except that it will use the vector address of \$FFF0 through \$FFF7. $\overline{IRQ_1}$ will have priority over $\overline{IRQ_2}$ if both occur at the same time. The Interrupt Mask Bit in the condition code register masks both interrupts (See Table 1).

Table 1 Interrupt Vector Location

Vector		Interrupt	
			MSB
Highest Priority	FFFE	FFFF	RES
	FFFC	FFFD	NMI
	FFFA	FFFB	Software Interrupt (SWI)
	FFF8	FFF9	IRQ ₁ (or IS3)
	FFF6	FFF7	ICF (Input Capture)
	FFF4	FFF5	OCF (Output Compare)
	FFF2	FFF3	TOF (Timer Overflow)
	FFF0	FFF1	SC ₁ (RDRF + ORFE + TDRE)
Lowest Priority			

The following pins are available in the Single Chip Mode, and are associated with Port 3 only.

● **Input Strobe (IS3) (SC₁)**

This sets an interrupt for the processor when the IS3 Enable bit is set. As shown in Figure 6 Input Strobe Timing, IS3 will fall t_{IS} minimum after data is valid on Port 3. If IS3 Enable is set in the I/O Port 3 Control/Status Register, an interrupt will occur. If the latch enable bit in the I/O Port 3 Control/Status Register is set, this strobe will latch the input data from another device when that device has indicated that it has valid data.

● **Output Strobe (OS3) (SC₂)**

This signal is used by the processor to strobe an external device, indicating valid data is on the I/O pins. The timing for the Output Strobe is shown in Figure 5. I/O Port 3 Control/Status Register is discussed in the following section.

The following pins are available in the Expanded Modes.

● **Read/Write (R/W) (SC₂)**

This TTL compatible output signals the peripherals and memory devices whether the CPU is in a Read ("High") or a Write ("Low") state. The normal standby state of this signal is Read ("High"). This output can drive one TTL load and 90 pF capacitance.

● **I/O Strobe (IOS) (SC₁)**

In the expanded non-multiplexed mode of operation, IOS internally decodes A₉ through A₁₅ as "0"s and A₈ as a "1". This allows external access of the 256 locations from \$0100 to \$01FF. The timing diagrams are shown as figure 2.

● **Address Strobe (AS) (SC₁)**

In the expanded multiplexed mode of operation, address strobe is output on this pin. This signal is used to latch the 8 LSB's of address which are multiplexed with data on Port 3. An 8-bit latch is utilized in conjunction with Address Strobe, as shown in figure 19. So I/O Port 3 can become data bus during the E pulse. The timing for this signal is shown in Figure 1 of Bus Timing. This signal is also used to disable the address from the multiplexed bus allowing a deselect time, t_{ASD} before the data is enabled to the bus.

■ **PORTS**

There are four I/O ports on the HD6801S MCU; three 8-bit ports and one 5-bit port. There are two control lines associated with one of the 8-bit ports. Each port has an associated write only Data Direction Register which allows each I/O line to be programmed to act as an input or an output*. A "1" in the corresponding Data Direction Register bit will cause that I/O line to be an output. A "0" in the corresponding Data Direction Register bit will cause that I/O line to be an input. There are four ports: Port 1, Port 2, Port 3, and Port 4. Their addresses and the addresses of their Data Direction registers are given in Table 2.

* The only exception is bit 1 of Port 2, which can either be data input or Timer output.

Table 2 Port and Data Direction Register Addresses

Ports	Port Address	Data Direction Register Address
I/O Port 1	\$0002	\$0000
I/O Port 2	\$0003	\$0001
I/O Port 3	\$0006	\$0004
I/O Port 4	\$0007	\$0005

● **I/O Port 1**

This is an 8-bit port whose individual bits may be defined as inputs or outputs by the corresponding bit in its data direction register. The 8 output buffers have three-state capability, allowing them to enter a high impedance state when the peripheral data lines are used as inputs. In order to be read properly, the voltage on the input lines must be greater than 2.0 V for a logic "1" and less than 0.8 V for a logic "0". As outputs, these lines are TTL compatible and may also be used as a source of up to 1 mA at 1.5 V to directly drive a Darlington base. After Reset, the I/O lines are configured as inputs. In all three modes, Port 1 is always parallel I/O.

● **I/O Port 2**

This port has five lines that may be defined as inputs or outputs by its data direction register. The 5 output buffers have three-state capability, allowing them to enter a high impedance state when used as an input. In order to be read properly, the voltage on the input lines must be greater than 2.0 V for a logic "1" and less than 0.8 V for a logic "0". As outputs, this port has no internal pullup resistors but will drive TTL inputs directly. For driving CMOS inputs, external pullup resistors are required. After Reset, the I/O lines are configured as inputs. Three pins on Port 2 (pins 10, 9, and 8 of the chip) are used to program the mode of operation during reset. The values of these pins at reset are latched into the three MSB's (bits 7, 6, and 5) of Port 2 which are read-only. This is explained in the Mode Selection Section.

In all three modes, Port 2 can be configured as I/O and provides access to the Serial Communications Interface and the Timer. Bit 1 is the only pin restricted to data input or Timer output.

● **I/O Port 3**

This is an 8-bit port that can be configured as I/O, a data bus, or an address bus multiplexed with the data bus — depending on the mode of operation hardware programmed by the user at reset. As a data bus, Port 3 is bi-directional. As an input for peripherals, it must be supplied regular TTL levels, that is, greater than 2.0 V for a logic "1" and less than 0.8 V for a logic "0".

Its TTL compatible three-state output buffers can drive one TTL load and 90 pF capacitance. In the Expanded Modes, after reset, the data direction register is inhibited and data flow depends on the state of the R/W line. The input strobe ($\overline{IS3}$) and the output strobe ($\overline{OS3}$) used for handshaking are explained later.

In the three modes, Port 3 assumes the following characteristics:

Single Chip Mode: Parallel Inputs/Outputs as programmed by its associated Data Direction Register. There are two control lines associated with this port in this mode, an input strobe and an output strobe, that can be used for handshaking. They are controlled by the I/O Port 3 Control/Status Register explained at the end of this section. Three options of Port 3 operations are summarized as follows: (1) Port 3 input data can be latched using $\overline{IS3}$ (SC_1) as a control signal, (2) $\overline{OS3}$ can be generated by either an CPU read or write to Port 3's Data Register, and (3) and $\overline{IRQ1}$ interrupt can be enabled by an $\overline{IS3}$ negative edge.

Port 3 latch and strobe timing is shown in Fig. 5 and Fig. 6.

Expanded Non-Multiplexed Mode: In this mode, Port 3 becomes the data bus ($D_0 \sim D_7$).

Expanded Multiplexed Mode: In this mode, Port 3 becomes both the data bus ($D_0 \sim D_7$) and lower bits of the address bus ($A_0 \sim A_7$). An address strobe output is true when the address is on the port.

I/O PORT 3 CONTROL/STATUS REGISTER

	7	6	5	4	3	2	1	0
\$000F	IS3 FLAG	$\overline{IS3}$ $\overline{IRQ1}$ ENABLE	X	OSS ENABLE	LATCH ENABLE	X	X	X

Bit 0; Not used.

Bit 1; Not used.

Bit 2; Not used.

Bit 3; **LATCH ENABLE.** This controls the input latch for I/O Port 3. If this bit is set "High" the input data will be latched with the falling edge of the Input Strobe, $\overline{IS3}$. This bit is cleared by reset, and the latch is "re-opened" with CPU read Port 3.

Bit 4; **OSS. (Output Strobe Select)** This bit will select if the Output Strobe should be generated at $\overline{OS3}$ (SC_2) by a write to I/O Port 3 or a read of I/O Port 3. When this bit is cleared the strobe is generated by a read Port 3. When this bit is set the strobe is generated by a write to Port 3.

Bit 5; Not used.

Bit 6; **$\overline{IS3}$ $\overline{IRQ1}$ ENABLE.** When set, interrupt will be enabled whenever $\overline{IS3}$ FLAG is set; when clear, interrupt is inhibited. This bit is cleared by reset.

Bit 7; **$\overline{IS3}$ FLAG.** This is a read-only status bit that is set by the falling edge of the input strobe, $\overline{IS3}$ (SC_1). It is cleared by a read of the Control/Status Register followed by a read or write of I/O Port 3. Reset will clear this bit.

• I/O Port 4

This is an 8-bit port that can be configured as I/O or as address output lines depending on the mode of operation. In order to be read properly, the voltage on the input lines must be greater than 2.0 V for a logic "1" and less than 0.8 V for a logic "0"

As outputs, each line is TTL compatible and can drive 1 TTL

load and 90 pF capacitance. After reset, the lines are configured as inputs. To use the pins as addresses, therefore, they should be programmed as outputs. In the three modes, Port 4 assumes the following characteristics:

Single Chip Mode: Parallel Inputs/Outputs as programmed by its associated Data Direction Register.

Expanded Non-Multiplexed Mode: Port 4 is configured as the lower order address lines ($A_0 \sim A_7$) by writing "1"s to the data direction register. When all eight address lines are not needed, the remaining lines, starting with the most significant bit, may be used as I/O (inputs only).

Expanded Multiplexed Mode: Port 4 is configured as the higher order address lines ($A_8 \sim A_{15}$) by writing "1"s to the data direction register. When all eight address lines are not needed, the remaining lines, starting with the most significant bit, may be used as I/O (Inputs only).

■ OPERATION MODES

The operation modes that HD6801S will operate after reset is determined by hardware that the user must wire on pins 10, 9, and 8 of the chip. These pins are the three LSB's (I/O 2, I/O 1, and I/O 0 respectively) of Port 2. They are latched into programmed control bits PC2, PC1, and PC0 when reset goes high. I/O Port 2 Register is shown below.

PORT 2 DATA REGISTER

	7	6	5	4	3	2	1	0
\$0003	PC2	PC1	PC0	I/O 4	I/O 3	I/O 2	I/O 1	I/O 0

An example of external hardware that could be used for Mode Selection is shown in Fig. 14. The HD14053B provides the isolation between the peripheral device and MCU during reset, which is necessary if data conflict can occur between peripheral device and Mode generation circuit.

As bits 5, 6 and 7 of Port 2 are read-only, the mode cannot be changed through software. The mode selections are shown in Table 3.

The HD6801S can operate in three basic modes;

(1) Single Chip Mode, (2) Expanded Multiplexed Mode (compatible with HMCS6800 peripheral family) (3) Expanded Non-Multiplexed Mode.

• Single Chip Mode

In the Single Chip Mode the Ports are configured as I/O.

This is shown in Figure 16 the single Chip Mode. In this mode, Port 3 will have two associated control lines, an input strobe and an output strobe for handshaking data.

• Expanded Non-Multiplexed Mode

In this mode the HD6801S will directly address HMCS6800 peripherals with no external logic. In this mode Port 3 becomes the data bus. Port 4 becomes the $A_0 \sim A_7$ address bus or partial address and I/O (inputs only). Port 2 can be parallel I/O, serial I/O, Timer, or any combination of them. Port 1 is parallel I/O only. In this mode the HD6801S is expandable to 256 locations. The eight address lines associated with Port 4 may be substituted for I/O (inputs only) if a fewer number of address lines will satisfy the application (See Figure 17).

- [NOTES] 1) Mode 7 as shown
 2) $RC \approx$ Reset time constant
 3) $R_1 = 10k\Omega$

Figure 14 Recommended Circuit for Mode Selection

Figure 15 HD14053B Multiplexers/Demultiplexers

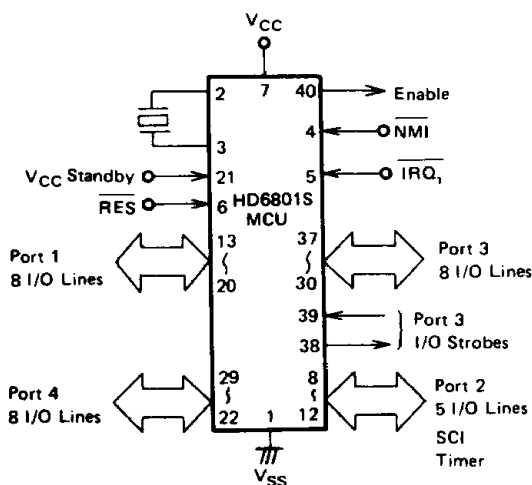

Figure 16 HD6801S MCU Single-Chip Mode

Figure 17 HD6801S MCU Expanded Non-Multiplexed Mode

HD6801S0, HD6801S5

Expanded Multiplexed Mode

In this mode Port 4 becomes higher order address lines with an alternative of substituting some of the address lines for I/O (inputs only). Port 3 is the data bus multiplexed with the lower order address lines differentiated by an output called Address Strobe. Port 2 is 5 lines of Parallel I/O, SCI, Timer, or any combination of them. Port 1 is 8 Parallel I/O lines. In this mode it is expandable to 65k bytes. (See Figure 18).

Lower order Address Bus Latches

Since the data bus is multiplexed with the lower order address bus in Port 3, latches are required to latch those address bits. The 74LS373 Transparent octal D-type latch can be used with the HD6801S to latch the least significant address byte. Figure 19 shows how to connect the latch to the HD6801S. The output control to the 74LS373 may be connected to ground.

Mode and Port Summary MCU Signal Description

This section gives a description of the MCU signals for the various modes. SC₁ and SC₂ are signals which vary with the mode that the chip is in.

MODE	PORT 1 Eight Lines	PORT 2 Five Lines	PORT 3 Eight Lines	PORT 4 Eight Lines	SC ₁	SC ₂
SINGLE CHIP	I/O	I/O	I/O	I/O	$\overline{IS3}$ (I)	$\overline{OS3}$ (O)
EXPANDED MUX	I/O	I/O	ADDRESS BUS (A ₀ ~A ₇) DATA BUS (D ₀ ~D ₇)	ADDRESS BUS* (A ₈ ~A ₁₅)	AS(O)	R/W(O)
EXPANDED NON-MUX	I/O	I/O	DATA BUS (D ₀ ~D ₇)	ADDRESS BUS* (A ₀ ~A ₇)	\overline{IOS} (O)	R/W(O)

*These lines can be substituted for I/O (Input Only) starting with the most significant address line.

I = Input
O = Output
R/W = Read/Write

$\overline{IS3}$ = Input Strobe
 $\overline{OS3}$ = Output Strobe
 \overline{IOS} = I/O Select

SC = Strobe Control
AS = Address Strobe

Table 3 Mode Selection Summary

Mode	P ₂₂ (PC2)	P ₂₁ (PC1)	P ₂₀ (PC0)	ROM	RAM	Interrupt Vectors	Bus Mode	Operating Mode
7	H	H	H	I	I	I	I	Single Chip
6	H	H	L	I	I	I	MUX(6)	Multiplexed/Partial Decode
5	H	L	H	I	I	I	NMUX(6)	Non-Multiplexed/Partial Decode
4	H	L	L	I(2)	I(1)	I	I	Single Chip Test
3	L	H	H	E	E	E	MUX	Multiplexed/No RAM & ROM
2	L	H	L	E	I	E	MUX	Multiplexed/RAM
1	L	L	H	I	I	E	MUX	Multiplexed/RAM & ROM
0	L	L	L	I	I	I(3)	MUX	Multiplexed Test

LEGEND:

- I – Internal
- E – External
- MUX – Multiplexed
- NMUX – Non-Multiplexed
- L – Logic "0"
- H – Logic "1"

[NOTES]

- 1) Internal RAM is addressed at \$X80
- 2) Internal ROM is disabled
- 3) \overline{RES} vector is external for 2 cycles after \overline{RES} goes "High"
- 4) Addresses associated with Ports 3 and 4 are considered external in Modes 0, 1, 2, and 3
- 5) Addresses associated with Port 3 are considered external in Modes 5 and 6
- 6) Port 4 default is user data input; address output is optional by writing to Port 4 Data Direction Register

■ MEMORY MAPS

The MCU can provide up to 65k bytes address space depending on the operating mode. A memory map for each operating mode is shown in Figure 20. The first 32 locations of each map are reserved for the MCU's internal register area, as shown in Table 4. With exceptions as indicated.

■ INTERRUPT FLOWCHART

The Interrupt flow chart is depicted in Figure 24 and is common to every interrupt excluding reset.

Table 4 Internal Register Area

Register	Address
Port 1 Data Direction Register***	00
Port 2 Data Direction Register***	01
Port 1 Data Register	02

■ PROGRAMMABLE TIMER

The HD6801S contains an on-chip 16-bit programmable timer which may be used to perform measurements on an input waveform while independently generating an output waveform. Pulse widths for both input and output signals may vary from a few microseconds to many seconds. The timer hardware consists of

- an 8-bit control and status register,
- a 16-bit free running counter,
- a 16-bit output compare register, and
- a 16-bit input capture register

A block diagram of the timer registers is shown in Figure 21.

● Free Running Counter (\$0009:\$000A)

The key element in the programmable timer is a 16-bit free running counter which is driven to increasing values by E (Enable). The counter value may be read by the CPU software at any time. The counter is cleared to zero by reset and may be considered a read-only register with one exception. Any CPU write to the counter's address (\$09) will always result in preset value of \$FFF8 being loaded into the counter regardless of the value involved in the write. This preset figure is intended for testing operation of the part, but may be of value in some applications.

● Output Compare Register (\$000B:\$000C)

The Output Compare Register is a 16-bit read/write register which is used to control an output waveform. The contents of this register are constantly compared with the current value of the free running counter. When a match is found, a flag is set (OCF) in the Timer Control and Status Register (TCSR) and the current value of the Output Level bit (OLVL) in the TCSR is clocked to the Output Level Register. Providing the Data Direction Register for Port 2, Bit 1 contains a "1" (Output), the output level register value will appear on the pin for Port 2

Bit 1. The values in the Output Compare Register and Output level bit may then be changed to control the output level on the next compare value. The Output Compare Register is set to \$FFFF during RES. The Compare function is inhibited for one cycle following a write to the high byte of the Output Compare Register to insure a valid 16-bit value is in the register before a compare is made.

● Input Capture Register (\$000D:\$000E)

The Input Capture Register is a 16-bit read-only register used to store the current value of the free running counter when the proper transition of an external input signal occurs. The input transition change required to trigger the counter transfer is controlled by the input Edge bit (IEDG) in the TCSR. The Data Direction Register bit for Port 2 Bit 0, should* be clear (zero) in order to gate in the external input signal to the edge detect unit in the timer.

The input pulse width must be at least two E-cycles to ensure an input capture under all conditions.

- * With Port 2 Bit 0 configured as an output and set to "1", the external input will still be seen by the edge detect unit.

● Timer Control and Status Register (TCSR) (\$0008)

The Timer Control and Status Register consists of an 8-bit register of which all 8 bits are readable but only the low order 5 bits may be written. The upper three bits contain read-only timer status information and indicate the followings.

- a proper transition has taken place on the input pin with a subsequent transfer of the current counter value to the input capture register.
- a match has been found between the value in the free running counter and the output compare register, and
- when \$0000 is in the free running counter.

Each of the flags may be enabled onto the HD6801 internal bus (IRQ₂) with an individual Enable bit in the TCSR. If the

Figure 21 Block Diagram of Programmable Timer

Timer Control and Status Register

1-bit in the HD6801S Condition Code Register has been cleared, a priority vectored interrupt will occur corresponding to the flag bit(s) set. A description for each bit follows:

- Bit 0 OLVL** Output Level – This value is clocked to the output level register on a successful output compare. If the DDR for Port 2 bit 1 is set, the value will appear on the output pin.
- Bit 1 IEDG** Input Edge – This bit controls which transition of an input will trigger a transfer of the counter to the input capture register. The DDR for Port 2 Bit 0 must be clear for this function to operate. IEDG = 0 Transfer takes place on a negative edge (“High”-to-“Low” transition). IEDG = 1 Transfer takes place on a positive edge (“Low”-to-“High” transition).
- Bit 2 ETOI** Enable Timer Overflow Interrupt – When set, this bit enables \overline{IRQ}_2 to occur on the internal bus for a TOF interrupt; when clear the interrupt is inhibited.
- Bit 3 EOCI** Enable Output Compare Interrupt – When set, this bit enables \overline{IRQ}_2 to appear on the internal bus for an output compare interrupt; when clear the interrupt is inhibited.
- Bit 4 EICI** Enable Input Capture Interrupt – When set, this bit enables \overline{IRQ}_2 to occur on the internal bus for an input capture interrupt; when clear the interrupt is inhibited.
- Bit 5 TOF** Timer Overflow Flag – This read-only bit is set when the counter contains \$FFFF. It is cleared by a read of the TCSR (with TOF set) followed by an CPU read of the Counter (\$09).
- Bit 6 OCF** Output Compare Flag – This read-only bit is set when a match is found between the output compare register and the free running counter. It is cleared by a read of the TCSR (with OCF set) followed by an CPU write to the output compare register (\$0B or \$0C).
- Bit 7 ICF** Input Capture Flag – This read-only status bit is set by a proper transition on the input; it is cleared by a read of the TCSR (with ICF set) followed by an CPU read of the Input Capture Register (\$0D).

■ SERIAL COMMUNICATION INTERFACE

The HD6801S contains a full-duplex asynchronous serial communication interface (SCI) on chip. The controller comprises a transmitter and a receiver which operate independently or each other but in the same data format and at the same data rate. Both transmitter and receiver communicate with the

CPU via the data bus and with the outside world via pins 2, 3, and 4 of Port 2. The hardware, software, and registers are explained in the following paragraphs.

• **Wake-Up Feature**

In a typical multi-processor application, the software protocol will usually contain a destination address in the initial byte(s) of the message. In order to permit non-selected MCU's to ignore the remainder of the message, a wake-up feature is included whereby all further interrupt processing may be optionally inhibited until the beginning of the next message. When the next message appears, the hardware re-enables (or “wakes-up”) the for the next message. The “wake-up” is automatically triggered by a string of ten consecutive 1's which indicates an idle transmit line. The software protocol must provide for the short idle period between any two consecutive messages.

• **Programmable Options**

The following features of the HD6801S serial I/O section are programmable:

- format – standard mark/space (NRZ)
- Clock – external or internal
- baud rate – one of 4 per given CPU ϕ_2 clock frequency or external clock $\times 8$ input
- wake-up feature – enabled or disabled
- Interrupt requests – enabled or masked individually for transmitter and receiver data registers
- clock output – internal clock enabled or disabled to Port 2 (Bit 2)
- Port 2 (bits 3 and 4) – dedicated or not dedicated to serial I/O individually for transmitter and receiver.

• **Serial Communication Hardware**

The serial communication hardware is controlled by 4 registers as shown in Figure 22. The registers include:

- an 8-bit control and status register
- a 4-bit rate and mode control register (write-only)
- an 8-bit read-only receive data register and
- an 8-bit write-only transmit data register.

In addition to the four registers, the serial I/O section utilizes bit 3 (serial input) and bit 4 (serial output) of Port 2. Bit 2 of Port 2 is utilized if the internal-clock-out or external-clock-in options are selected.

Transmit/Receive Control and Status (TRCS) Register

The TRCS register consists of an 8-bit register of which all 8 bits may be read while only bits 0~4 may be written. The register is initialized to \$20 by reset. The bits in the TRCS register are defined as follows:

Transmit/Receive Control and Status Register

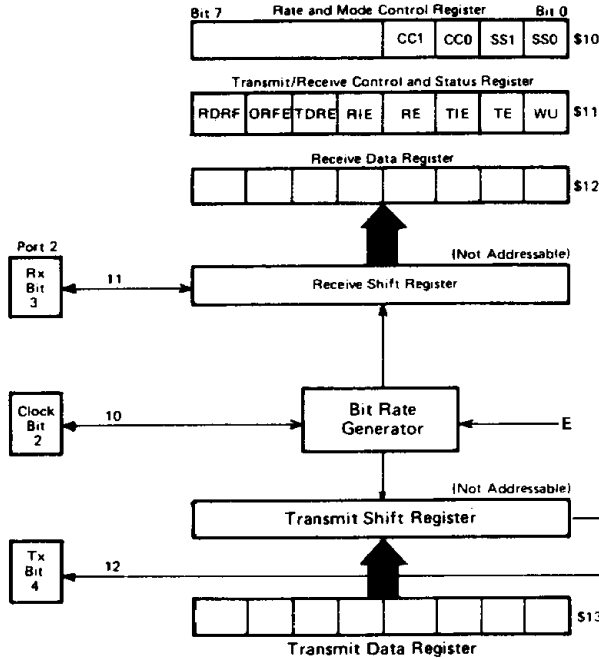

Figure 22 Serial I/O Registers

- Bit 0 WU** "Wake-up" on Next Message – set by HD6801S software and cleared by hardware on receipt of ten consecutive 1's or reset of RE flag. It should be noted that RE flag should be set in advance of CPU set of WU flag.
- Bit 1 TE** Transmit Enable – set by HD6801S to produce preamble of nine consecutive 1's and to enable gating of transmitter output to Port 2, bit 4 regardless of the DDR value corresponding to this bit; when clear, serial I/O has no effect on Port 2 bit 4.
TE set should be after at least one bit time of data transmit rate from the set-up of transmit data rate and mode.
- Bit 2 TIE** Transmit Interrupt Enable – when set, will permit an IRQ₂ interrupt to occur when bit 5 (TDRE) is set; when clear, the TDRE value is masked from the bus.
- Bit 3 RE** Receiver Enable – when set, gates Port 2 bit 3 to input of receiver regardless of DDR value for this bit; when clear, serial I/O has no effect on Port 2 bit 3.
- Bit 4 RIE** Receiver Interrupt Enable – when set, will permit an IRQ₂ interrupt to occur when bit 7 (RDRF) or bit 6 (ORFE) is set; when clear, the interrupt is masked.
- Bit 5 TDRE** Transmit Data Register Empty – set by hardware when a transfer is made from the transmit data register to the output shift register. The TDRE bit is cleared by reading the status register, then

writing a new byte into the transmit data register, TDRE is initialized to 1 by reset.

- Bit 6 ORFE** Over-Run-Framing Error – set by hardware when an overrun or framing error occurs (receive only). An overrun is defined as a new byte received with last byte still in Data Register/Buffer. A framing error has occurred when the byte boundaries in bit stream are not synchronized to bit counter. The ORFE bit is cleared by reading the status register, then reading the Receive Data Register, or by reset.
- Bit 7 RDRF** Receiver Data Register Full – Set by hardware when a transfer from the input shift register to the receiver data register is made. The RDRF bit is cleared by reading the status register, then reading the Receive Data Register, or by reset.

Rate and Mode Control Register

The Rate and Mode Control register controls the following serial I/O variables:

- Baud rate
- format
- clocking source, and
- Port 2 bit 2 configuration

The register consists of 4 bits all of which are write-only and cleared by reset. The 4 bits in the register may be considered as a pair of 2-bit fields. The two low order bits control the bit rate for internal clocking and the remaining two bits control the format and clock select logic. The register definition is as follows:

Rate and Mode Control Register							
7	6	5	4	3	2	1	0
X	X	X	X	CC1	CC0	SS1	SS0

ADDR : \$0010

Bit 0 **SS0** } Speed Select – These bits select the Baud rate for
 Bit 1 **SS1** } the internal clock. The four rates which may be
 selected are a function of the CPU ϕ_2 clock
 frequency. Table 5 lists the available Baud rates.

Bit 2 **CC0** } Clock Control and Format Select – this 2-bit field
 Bit 3 **CC1** } controls the format and clock select logic. Table 6
 defines the bit field.

Table 5 SCI Bit Times and Rates

SS1 : SS0	XTAL	2.4576 MHz	4.0 MHz	4.9152 MHz*
	E	614.4 kHz	1.0 MHz	1.2288 MHz
0 0	E ÷ 16	26 μ s/38,400 Baud	16 μ s/62,500 Baud	13 μ s/76,800 Baud
0 1	E ÷ 128	208 μ s/4,800 Baud	128 μ s/7812.5 Baud	104.2 μ s/9,600 Baud
1 0	E ÷ 1024	1.67 ms/600 Baud	1.024 ms/976.6 Baud	833.3 μ s/1,200 Baud
1 1	E ÷ 4096	6.67 ms/150 Baud	4.096 ms/244.1 Baud	3.33 ms/300 Baud

* HD6801S5 Only

Table 6 SCI Format and Clock Source Control

CC1 : CC0	Format	Clock Source	Port 2 Bit 2	Port 2 Bit 3	Port 2 Bit 4
0 0	–	–	–	**	**
0 1	NRZ	Internal	Not Used	**	**
1 0	NRZ	Internal	Output*	**	**
1 1	NRZ	External	Input	**	**

* Clock output is available regardless of values for bits RE and TE.
 ** Bit 3 is used for serial input if RE = "1" in TRCS; bit 4 is used for serial output if TE = "1" in TRCS.

Internally Generated Clock

If the user wishes for the serial I/O to furnish a clock, the following requirements are applicable:

- the values of RE and TE are immaterial.
- CC1, CC0 must be set to 10
- the maximum clock rate will be E ÷ 16.
- the clock will be at 1× the bit rate and will have a rising edge at mid-bit.

Externally Generated Clock

If the user wishes to provide an external clock for the serial I/O, the following requirements are applicable:

- the CC1, CC0, field in the Rate and Mode Control Register must be set to 11,
- the external clock must be set to 8 times (×8) the desired baud rate and
- the maximum external clock frequency is 1.0 MHz.

Serial Operations

The serial I/O hardware should be initialized by the HD6801S software prior to operation. This sequence will normally consist of;

- writing the desired operation control bits to the Rate and Mode Control Register and
- writing the desired operational control bits in the Transmit/Receive Control and Status Register.

The Transmitter Enable (TE) and Receiver Enable (RE) bits may be left set for dedicated operations.

Transmit Operations

The transmit operation is enabled by the TE bit in the Transmit/Receive Control and Status Register. This bit when set, gates the output of the serial transmit shift register to Port 2 Bit 4 and takes unconditional control over the Data Direction Register value for Port 2, Bit 4.

Following a RES the user should configure both the Rate and Mode Control Register and the Transmit/Receive Control and Status Register for desired operation. Setting the TE bit during this procedure initiates the serial output by first transmitting a nine-bit preamble of 1's. Following the preamble, internal synchronization is established and the transmitter section is ready for operation.

At this point one of two situation exist:

- 1) if the Transmit Data Register is empty (TDRE = 1), a continuous string of ones will be sent indicating an idle line, or,
- 2) if data has been loaded into the Transmit Data Register (TDRE = 0), the word is transferred to the output shift register and transmission of the data word will begin.

During the data transmit, the 0 start bit is first transmitted. Then the 8 data bits (beginning with bit 0) followed by the stop bit, are transmitted. When the Transmitter Data Register has been emptied, the hardware sets the TDRE flag bit.

If the HD6801S fails to respond to the flag within the proper time, (TDRE is still set when the next normal transfer from the parallel data register to the serial output register should occur) then a 1 will be sent (instead of a 0) at "Start" bit time, followed by more 1's until more data is supplied to the data register. No 0's will be sent while TDRE remains a 1.

Receive Operation

The receive operation is enabled by the RE bit which gates in the serial input through Port 2 Bit 3. The receiver section operation is conditioned by the contents of the Transmit/Receive Control and Status Register and the Rate and Mode Control Register.

The receiver bit interval is divided into 8 sub-intervals for internal synchronization. In the NRZ Mode, the received bit stream is synchronized by the first 0 (space) encountered.

The approximate center of each bit time is strobed during the next 10 bits. If the tenth bit is not a 1 (stop bit) a framing error is assumed, and bit ORFE is set. If the tenth bit as a 1, the data is transferred to the Receive Data Register, and interrupt flag RDRF is set. If RDRF is still set at the next tenth bit time, ORFE will be set, indicating an over-run has occurred. When the HD6801S responds to either flag (RDRF or ORFE) by reading the status register followed by reading the Data Register, RDRF (or ORFE) will be cleared.

RAM CONTROL REGISTER

This register, which is addressed at \$0014, gives status information about the standby RAM. A "0" in the RAM enable bit (RAME) will disable the standby RAM, thereby protecting it at power down if V_{CC} Standby is held greater than V_{SBB} volts, as explained previously in the signal description for V_{CC} Standby.

- Bit 0 Not used.
- Bit 1 Not used.
- Bit 2 Not used.
- Bit 3 Not used.
- Bit 4 Not used.
- Bit 5 Not used.

Bit 6 RAME The RAM Enable control bit allows the user the ability to disable the standby RAM. This bit is set to a logic "1" by RES which enables the standby RAM and can be written to one or zero under program control. When the RAM is disabled, data is read from external memory.

Bit 7 STBY PWR The Standby Power bit is cleared when the standby voltage is removed. This bit is a read/write status flag that the user can read which indicates that the standby RAM voltage has been applied, and the data in the standby RAM is valid.

GENERAL DESCRIPTION OF INSTRUCTION SET

The HD6801S is upward object code compatible with the HD6800 as it implements the full HMCS6800 instruction set. The execution times of key instructions have been reduced to increase throughout. In addition, new instructions have been added; these include 16-bit operations and a hardware multiply. Included in the instruction set section are the following:

- CPU Programming Model (Figure 23)
- Addressing modes
- Accumulator and memory instructions – Table 7
- New instructions
- Index register and stack manipulations instructions – Table 8
- Jump and branch instructions – Table 9

- Condition code register manipulation instructions – Table 10
- Instructions Execution times in machine cycles – Table 11
- Summary of cycle by cycle operation – Table 12
- Op codes Map – Table 13

CPU Programming Model

The programming model for the HD6801S is shown in Figure 23. The double (D) accumulator is physically the same as the Accumulator A concatenated with the Accumulator B so that any operation using accumulator D will destroy information in A and B.

Figure 23 CPU Programming Model

CPU Addressing Modes

The HD6801S eight-bit microcomputer unit has seven address modes that can be used by a programmer, with the addressing mode a function of both the type of instruction and the coding within the instruction. A summary of the addressing modes for a particular instruction can be found in Table 11 along with the associated instruction execution time that is given in machine cycles. With a clock frequency of 4 MHz, these times would be microseconds.

Accumulator (ACCX) Addressing

In accumulator only addressing, either accumulator A or accumulator B is specified. These are one-byte instructions.

Immediate Addressing

In immediate addressing, the operand is contained in the second byte of the instruction except LDS and LDX which have the operand in the second and third bytes of the instruction. The CPU addresses this location when it fetches the immediate instruction for execution. These are two or three-byte instructions.

Table 7 Accumulator & Memory Instructions (Continued)

The Condition Code Register notes are listed after Table 10.

Direct Addressing

In direct addressing, the address of the operand is contained in the second byte of the instruction. Direct addressing allows the user to directly address the lowest 256 bytes in the machine i.e., locations zero through 255. Enhanced execution times are achieved by storing data in these locations. In most configurations, it should be a random access memory. These are two-byte instructions.

Extended Addressing

In extended addressing, the address contained in the second byte of the instruction is used as the higher eight-bits of the address of the operand. The third byte of the instruction is used as the lower eight-bits of the address for the operand. This is an absolute address in memory. These are three-byte instructions.

Indexed Addressing

In indexed addressing, the address contained in the second byte of the instruction is added to the index register's lowest

eight bits in the CPU. The carry is then added to the higher order eight bits of the index register. This result is then used to address memory. The modified address is held in a temporary address register so there is no change to the index register. These are two-byte instructions.

Implied Addressing

In the implied addressing mode the instruction gives the address (i.e., stack pointer, index register, etc.). These are one-byte instructions.

Relative Addressing

In relative addressing, the address contained in the second byte of the instruction is added to the program counter's lowest eight bits plus two. The carry or borrow is then added to the high eight bits. This allows the user to address data within a range of -126 to +129 bytes of the present instruction. These are two-byte instructions.

● **New Instructions**

In addition to the existing 6800 Instruction Set, the following new instructions are incorporated in the HD6801S Microcomputer.

- ABX** Adds the 8-bit unsigned accumulator B to the 16-bit X-Register taking into account the possible carry out of the low order byte of the X-Register.
- ADDD** Adds the double precision ACCD* to the double precision value M:M+1 and places the results in ACCD.
- ASLD** Shifts all bits of ACCD one place to the left. Bit 0 is loaded with zero. The C bit is loaded from the most significant bit of ACCD.
- LDD** Loads the contents of double precision memory location into the double accumulator A:B. The condition codes are set according to the data.
- LSRD** Shifts all bits of ACCD one place to the right. Bit 15 is loaded with zero. The C bit is loaded from the least significant bit to ACCD.
- MUL** Multiplies the 8 bits in accumulator A with the 8 bits in accumulator B to obtain a 16-bit unsigned number in A:B, ACCA contains MSB of result.
- PSHX** The contents of the index register is pushed onto the stack at the address contained in the stack pointer. The stack pointer is decremented by 2.
- PULX** The index register is pulled from the stack beginning at the current address contained in the stack pointer +1. The stack pointer is incremented by 2 in total.
- STD** Stores the contents of double accumulator A:B in memory. The contents of ACCD remain unchanged.
- SUBD** Subtracts the contents of M:M + 1 from the contents of double accumulator AB and places the result in ACCD.
- BRN** Never branches. If effect, this instruction can be considered a two byte NOP (No operation) requiring three cycles for execution.
- CPX** Internal processing modified to permit its use with any conditional branch instruction.

*ACCD is the 16 bit register (A:B) formed by concatenating the A and B accumulators. The A-accumulator is the most significant byte.

● Summary of Cycle by Cycle Operation

Table 12 provides a detailed description of the information present on the Address Bus, Data Bus, and the Read/Write line (R/W) during each cycle for each instruction.

This information is useful in comparing actual with expected results during debug of both software and hardware as the

control program is executed. The information is categorized in groups according to addressing mode and number of cycles per instruction. (In general, instructions with the same addressing mode and number of cycles execute in the same manner; exceptions are indicated in the table).

Table 12 Cycle by Cycle Operation

• Summary of Undefined Instruction Operations

The HD6801S has 36 undefined instructions. When these are carried out, the contents of Register and Memory in MCU change at random.

When the op codes (4E, 5E) are used to execute, the MCU continues to increase the program counter and it will not stop until the Reset signal enters. These op codes are used to test the LSI.

- (NOTES) 1) Undefined Op codes are marked with .
 2) () indicate that the number in parenthesis must be added to the cycle count for that instruction.
 3) The instructions shown below are all 3 bytes and are marked with "***". Immediate addressing mode of SUBD, CPX, LDS, ADD, LDD and LDX instructions, and undefined op codes (8F, CD, CF).
 4) The Op codes (4E, 5E) are 1 byte/∞ cycles instructions, and are marked with "****"

■ PRECAUTIONS

● PRECAUTION CONCERNING COUNTER TIMER

- (1) Timer Output (P₂₁)
After CPU reset, P₂₁ is uncertain until the value of the free running counter equals the value of the output compare register or until the free running counter completes a software time-out cycle.
- (2) Initialization of ICF
ICF should be cleared by software after initiating a reset, otherwise ICF may be set if P₂₁ is "low" after initiating a reset.

● PRECAUTION CONCERNING WRITE-ONLY REGISTER

The write-only register cannot be changed like DDR for I/O ports using Read/Modify/Write instructions.

- (1) The CPU cannot read the write-only register. Proceed with

Read/Modify/Write instructions as follows:

- (i) read the data of specified address;
- (ii) modify the data; and
- (iii) write the modified data to original address.

The Read/Modify/Write instructions cannot be used with the write-only register like DDR.

- (2) Store instructions can be used for writing to the write-only register.

*Read/Modify/Write instructions—NEG, COM, LSR, ROR, ASR, ASL, ROL, DEC, INC, TST, CLR

■ PRECAUTION CONCERNING HD6801 SERIES SCI, TIMER STATUS FLAG

● Caution for the HD6801 Family SCI, TIMER Status Flag

The flags shown in Table 14 are cleared by reading/writing (flag reset condition) the data register corresponding to each flag after reading the status register (flag reset condition 1).

To clear the flag correctly, use the following procedure:

1. Read the status register
2. Test the flag
3. Read the data register

The SCI, Timer status flag is cleared by reading a "1" for each status flag and then reading the data register. SCI software routines should read the received data after confirming a "1" as the received status flag. Avoid reading dummy data after a "0" for the received status flag.

Table 14 Status Flag Reset Conditions

	Status Flag	Flag Reset Condition 1 (Status Register)	Flag Reset Condition 2 (Data Register)
TIMER	ICF	When each flag is "1", TRCSR/Read	ICR/Read
	OCF		OCR/Read
	TOF		TC/Read
SCI	RDRF	When Each flag is "1", TRCSR/Read	RDR/Read
	ORFE		Read
	TDRE		TDR/Write

● TERMINAL CONDITION DURING RESET, AFTER RESET

Table 15 Terminal Condition During Reset, After Reset

CPU Mode		0	1	2	3	4	5	6	7
During Reset	Port 1	I Z	←	←	←	←	←	←	←
	Port 2	I Z	←	←	←	←	←	←	←
	Port 3	I Z	←	←	←	←	←	←	←
	Port 4	I H	←	←	←	←	←	←	←
	SC ₁	I/O H	←	←	←	I H	O H	I/O H	I H
	SC ₂	O H	←	←	←	←	←	←	←
After Reset	Port 1	I Z	←	←	←	←	←	←	←
	Port 2	I Z	←	←	←	←	←	←	←
	Port 3	I/O ABL/DB	←	←	←	I Z	I DB	I/O ABL/DB	I Z
	Port 4	O ABH	←	←	←	I H	←	←	←
	SC ₁	O AS	←	←	←	I H	O IOS	O AS	I H
	SC ₂	O R/W	←	←	←	O OS3	O R/W	←	O OS3

I : Input
O : Output
I/O : Input/Output
Upper : Input Condition
Lower : Level, Terminal Function

H : High Level
L : Low Level
Z : High Impedance

DB : Data Bus
ABL : Address Bus Low
ABH : Address Bus High

AS : Address Strobe
R/W : Read/Write
IOS : IOS Signal
OS3 : OS3 Signal
