

## 1) Introduction

Increasingly power supplies used in applications such as home appliance, office automation, communications and industrial area need to operate on the main AC line 100V and 200V as products are manufactured for global markets.

Traditionally power supplies have been designed to operate on either 100V or 200V AC mains, as products were manufactured for local markets.

The MK-series permits the use of 100V and 200V AC line source by automatic sensing of the main AC line.

This application guide describes the MK-series, its electrical circuit design, mounting procedure and applications.

## 2) The MK-series

### 2-1 General description

MK-series is designed to operate with input range 90-132 Volts AC and 180-276 Volts AC with output power capability of 50-150 Watts (higher output power can be achieved by using external triac together with the MK series)

The MK-series automatically determines whether the input voltage level is 100V or 200V, and will switch accordingly to voltage doubler mode or full wave bridge rectification mode. The rectified voltage level for both modes is similar. The switching between the voltage doubler mode and the full wave bridge rectification mode is done by built-in triac, so minimising use of external components.

The MK-series is housed in a 7 pin single in line package which is light weight, compact and ideal for portable equipment.

### 2-2 Benefits/Features

- a) Power supply damage caused by selecting wrong rectification mode in manually operated 100V/200V switch is eliminated together with reduced possibility of inductive noise on electrical line.
- b) Power transformer does not have to be designed for full range input voltage, hence the power output is increased.
- c) Few external components required, simplifying design and improved efficiency.
- d) Fully mold package with insulation voltage resistance AC 2KV/1 minute. The internal thickness of the mold is  $>0.71\text{mm}$ .
- e) Built-in protective device prevent damage resulting from instantaneous outages and voltage drops. (MK1210)
- f) Doubler voltage rectification mode can be delayed using external capacitor on the MK1210.

## 2-6 Package information

### 3) Functional description

#### 3-1 Operation of the Voltage doubler and the Full wave rectification modes.

The MK-series uses voltage doubler rectification when operating at 100V and full wave bridge rectification when operating at 200V. Figures 3a and 3d show the 100V to the 200V mode switching stage.

##### a) Voltage doubler rectification

In the 100V mode, the Triac is ON. Positive half cycle charge capacitor C1 as shown by ----- line in figure 3a. The negative half cycle charge capacitor C2 as shown by - - - - - line in figure 3a.

The applied 100V voltage results in a peak voltage of 142V across C1 and C2. Note as an approximation whenever the input voltage is at instantaneous minimum, one capacitor is at its minimum, but the other capacitor is half way between peak and the minimum voltage. These rectified voltages result in a ripple wave having an average value of 240V.

##### b) Full wave bridge rectification

In the 200V mode, the Triac is OFF. Capacitors C1 and C2 in series are charged to peak line voltage each half cycles as shown by ----- and - - - - - lines in figure 3b. The applied 200V results in a peak voltage of 282V across the series capacitors C1 and C2. These rectified voltage results in a ripple wave having an average value of 260V.

#### 3-2 MK-series functional description

When the mains is applied the Triac is in the OFF state. As the mains voltage level rises, typically at 50V the Triac is turned ON as a result of transistor Q1 biased ON via the resistor ladder R3, R4 and zener diode DZ1 (see section 2-5, MK1110 and MK1210 equivalent circuits). At this instant the voltage doubler mode starts.

When the input voltage reaches typically 155V, transistor Q2 is biased ON via resistor ladder R6, R7 and zener DZ2 which pulls low the R4 and DZ1 connection switching OFF transistor Q1 in-turn switching Triac OFF. At this point the MK-series pulls out of voltage doubler rectification mode and full wave bridge rectification mode starts, refer to figure 3e.

The MK1210 has built-in protection function to latch into the full wave rectification mode. During full wave rectification transistors Q2 and Q4 are biased ON, keeping Triac OFF. If mains voltage drop or there is mains failure, the MK1210 transistors Q2 and Q4 function as a latch in the ON state thereby not allowing Triac to turn ON. The rectified voltage drops linearly, refer to figure 3f.

When the mains is reinstated and has not dropped below typically 50VAC, transistors Q2 and Q4 stay latched ON, not allowing MK1210 to drop into voltage doubler mode and continue to function as full wave bridge rectification. Only when the mains is dropped below 50VAC transistor Q2 and Q4 are biased OFF turning Triac ON allowing voltage doubler rectification.

The MK1210 has a delay time function. By means of capacitor (value dependent), refer to section 4-2-2, connected across pin 5 and pin 6, delay can be set from switch ON (mains applied) to MK1210 dropping into voltage doubler mode.

## 5-2 接触熱抵抗 $\theta_{jf}$ , $\theta_{cf}$

## 5-3 放熱板面積と熱抵抗

## 5-4 推奨実装例

放熱フィンへの実装は下記の方法を推奨します。

※1 例1は小出力の場合に推奨します。それ以上の場合は、例2のような2点締めによる確実な実装を推奨します。

なお、例1で使用する取付クリップはオプション部品として用意してあります。

※2 接触熱抵抗を少なくするためにオイルコンパウンドの使用をお勧めします。

※3 フィンはバリ等のない平坦なものを使用してください。

※4 プリント基板への挿入はリードのストッパーまでに行ってください。
