## Functional Description

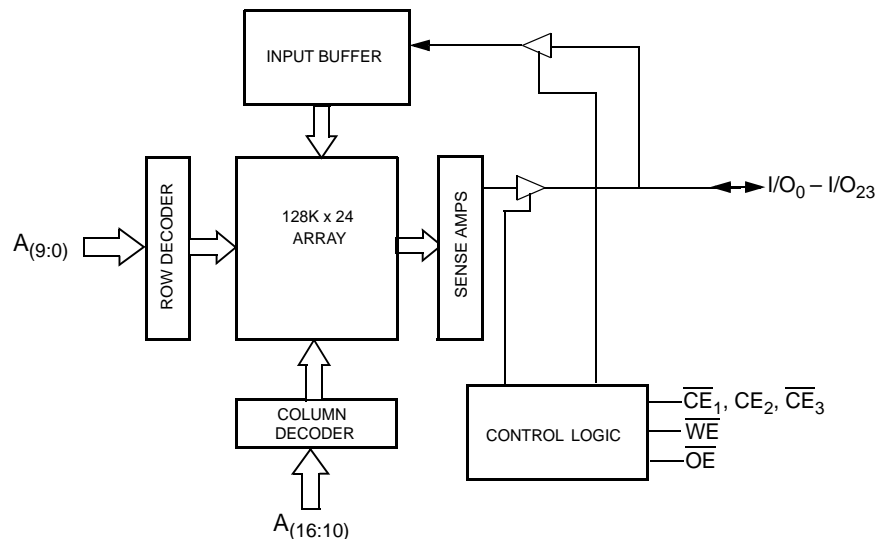

The CY7C1024DV33 is a high performance CMOS static RAM organized as 128K words by 24 bits. This device has an automatic power down feature that significantly reduces power consumption when deselected.

To write to the device, enable the chip ( $\overline{CE}_1$  LOW,  $CE_2$  HIGH, and  $\overline{CE}_3$  LOW), while forcing the Write Enable (WE) input LOW.

To read from the device, enable the chip by taking  $\overline{CE}_1$  LOW,  $CE_2$  HIGH, and  $\overline{CE}_3$  LOW while forcing the Output Enable (OE) LOW and the Write Enable (WE) HIGH. See the [Truth Table](#) on page 7 for a complete description of Read and Write modes.

The 24 I/O pins ( $I/O_0$  to  $I/O_{23}$ ) are placed in a high impedance state when the device is deselected ( $\overline{CE}_1$  HIGH,  $CE_2$  LOW, or  $\overline{CE}_3$  HIGH) or when the output enable ( $\overline{OE}$ ) is HIGH during a write operation. ( $\overline{CE}_1$  LOW,  $CE_2$  HIGH,  $\overline{CE}_3$  LOW, and WE LOW).

**Notes**

- Valid SRAM operation does not occur until the power supplies have reached the minimum operating  $V_{DD}$  (3.0V). 100  $\mu s$  ( $t_{power}$ ) after reaching the minimum operating  $V_{DD}$ , normal SRAM operation can begin including reduction in  $V_{DD}$  to the data retention ( $V_{CCDR}$ , 2.0V) voltage.
- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5V, and input pulse levels of 0 to 3.0V. Test conditions for the read cycle use output loading as shown in part a) of Figure 2, unless specified otherwise.
- $t_{POWER}$  gives the minimum amount of time that the power supply is at typical  $V_{CC}$  values until the first memory access is performed.
- $t_{HZOE}$ ,  $t_{HZCE}$ ,  $t_{HZWE}$ ,  $t_{LZOE}$ ,  $t_{LZCE}$ , and  $t_{LZWE}$  are specified with a load capacitance of 5 pF as in part (b) of Figure 2. Transition is measured  $\pm 200$  mV from steady state voltage.
- These parameters are guaranteed by design and are not tested.

t <sub>R</sub> <sup>[12]</sup>	Operation Recovery Time		t <sub>RC</sub>			ns

**Data Retention Waveform**

**Notes**

9. The internal write time of the memory is defined by the overlap of  $\overline{CE}_1$  and  $\overline{CE}_2$  and  $\overline{CE}_3$  LOW and  $\overline{WE}$  LOW. Chip enables must be active and  $\overline{WE}$  must be LOW to initiate a write. The transition of any of these signals terminate the write. The input data setup and hold timing is referenced to the leading edge of the signal that terminates the write.
10. The minimum write cycle time for Write Cycle No. 3 ( $\overline{WE}$  controlled,  $\overline{OE}$  LOW) is the sum of t<sub>HZWE</sub> and t<sub>SD</sub>.
11. Tested initially and after any design or process changes that may affect these parameters.
12. Full device operation requires linear V<sub>CC</sub> ramp from V<sub>DR</sub> to V<sub>CC(min)</sub> ≥ 50 μs or stable at V<sub>CC(min)</sub> ≥ 50 μs.

Notes

- 13. Device is continuously selected.  $\overline{\text{OE}}, \overline{\text{CE}} = V_{\text{IL}}$ .
- 14.  $\overline{\text{WE}}$  is HIGH for read cycle.
- 15. Address valid before or similar to  $\overline{\text{CE}}$  transition LOW.
- 16. Data I/O is high impedance if  $\overline{\text{OE}} = V_{\text{IH}}$ .
- 17. If  $\overline{\text{CE}}$  goes HIGH simultaneously with  $\overline{\text{WE}}$  going HIGH, the output remains in a high impedance state.
