

600mA, 500kHz Step-Down Switching Regulator in SOT-23 and DFN Packages

FEATURES

- **Wide Input Range: 3.6V to 36V**
- 5V at 600mA from 16V to 36V Input
- 3.3V at 600mA from 12V to 36V Input
- 5V at 500mA from 6.3V to 36V Input
- 3.3V at 500mA from 4.5V to 36V Input
- Fixed Frequency 500kHz Operation
- Uses Tiny Capacitors and Inductors
- Soft-Start
- Internally Compensated
- Low Shutdown Current: <math><2\mu\text{A}</math>
- Output Adjustable Down to 1.25V
- Low Profile (1mm) SOT-23 (ThinSOT™) and (2mm × 3mm × 0.75mm) 6-Pin DFN Packages

APPLICATIONS

- Automotive Battery Regulation
- Industrial Control Supplies
- Wall Transformer Regulation
- Distributed Supply Regulation
- Battery-Powered Equipment

DESCRIPTION

The LT®1933 is a current mode PWM step-down DC/DC converter with an internal 0.75A power switch, packaged in a tiny 6-lead SOT-23. The wide input range of 3.6V to 36V makes the LT1933 suitable for regulating power from a wide variety of sources, including unregulated wall transformers, 24V industrial supplies and automotive batteries. Its high operating frequency allows the use of tiny, low cost inductors and ceramic capacitors, resulting in low, predictable output ripple.

Cycle-by-cycle current limit provides protection against shorted outputs, and soft-start eliminates input current surge during start up. The low current (<math><2\mu\text{A}</math>) shutdown provides output disconnect, enabling easy power management in battery-powered systems.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: The LT1933E is guaranteed to meet performance specifications from 0°C to 70°C . Specifications over the -40°C to 85°C operating temperature range are assured by design, characterization and correlation with statistical process controls. The LT1933I specifications are

guaranteed over the -40°C to 125°C temperature range. The LT1933H specifications are guaranteed over the -40°C to 150°C temperature range.

Note 3: Current limit guaranteed by design and/or correlation to static test. Slope compensation reduces current limit at higher duty cycle.

Note 4: Current flows out of pin.

Note 5: Current flows into pin.

TYPICAL PERFORMANCE CHARACTERISTICS

TYPICAL PERFORMANCE CHARACTERISTICS

PIN FUNCTIONS (SOT-23/DFN)

BOOST (Pin 1): The BOOST pin is used to provide a drive voltage, higher than the input voltage, to the internal bipolar NPN power switch.

GND (Pin 2/Pin 5 and Exposed Pad, Pin 7): Tie the GND pin to a local ground plane below the LT1933 and the circuit components. Return the feedback divider to this pin.

FB (Pin 3/Pin 6): The LT1933 regulates its feedback pin to 1.245V. Connect the feedback resistor divider tap to this pin. Set the output voltage according to $V_{OUT} = 1.245V (1 + R1/R2)$. A good value for R2 is 10k.

SHDN (Pin 4): The SHDN pin is used to put the LT1933 in shutdown mode. Tie to ground to shut down the LT1933. Tie to 2.3V or more for normal operation. If the shutdown feature is not used, tie this pin to the V_{IN} pin. SHDN also provides a soft-start function; see the Applications Information section.

V_{IN} (Pin 5/Pin 2): The V_{IN} pin supplies current to the LT1933's internal regulator and to the internal power switch. This pin must be locally bypassed.

SW (Pin 6): The SW pin is the output of the internal power switch. Connect this pin to the inductor, catch diode and boost capacitor.

BLOCK DIAGRAM

OPERATION (Refer to Block Diagram)

The LT1933 is a constant frequency, current mode step down regulator. A 500kHz oscillator enables an RS flip-flop, turning on the internal 750mA power switch Q1. An amplifier and comparator monitor the current flowing between the V_{IN} and SW pins, turning the switch off when this current reaches a level determined by the voltage at V_C . An error amplifier measures the output voltage through an external resistor divider tied to the FB pin and servos the V_C node. If the error amplifier's output increases, more current is delivered to the output; if it decreases, less current is delivered. An active clamp (not shown) on the V_C node provides current limit. The V_C node is also clamped to the voltage on the SHDN pin; soft-start is implemented by generating a voltage ramp at the SHDN pin using an external resistor and capacitor.

An internal regulator provides power to the control circuitry. This regulator includes an undervoltage lockout to prevent switching when V_{IN} is less than $\sim 3.35V$. The SHDN pin is used to place the LT1933 in shutdown, disconnecting the output and reducing the input current to less than $2\mu A$.

The switch driver operates from either the input or from the BOOST pin. An external capacitor and diode are used to generate a voltage at the BOOST pin that is higher than the input supply. This allows the driver to fully saturate the internal bipolar NPN power switch for efficient operation.

The oscillator reduces the LT1933's operating frequency when the voltage at the FB pin is low. This frequency foldback helps to control the output current during startup and overload.

APPLICATIONS INFORMATION

FB Resistor Network

The output voltage is programmed with a resistor divider between the output and the FB pin. Choose the 1% resistors according to:

$$R1 = R2(V_{OUT}/1.245 - 1)$$

$R2$ should be 20k or less to avoid bias current errors. Reference designators refer to the Block Diagram.

Input Voltage Range

The input voltage range for LT1933 applications depends on the output voltage and on the absolute maximum ratings of the V_{IN} and BOOST pins.

The minimum input voltage is determined by either the LT1933's minimum operating voltage of $\sim 3.35V$, or by its maximum duty cycle. The duty cycle is the fraction of time that the internal switch is on and is determined by the input and output voltages:

$$DC = (V_{OUT} + V_D)/(V_{IN} - V_{SW} + V_D)$$

where V_D is the forward voltage drop of the catch diode ($\sim 0.4V$) and V_{SW} is the voltage drop of the internal switch

($\sim 0.4V$ at maximum load). This leads to a minimum input voltage of:

$$V_{IN(MIN)} = (V_{OUT} + V_D)/DC_{MAX} - V_D + V_{SW}$$

with $DC_{MAX} = 0.88$

The maximum input voltage is determined by the absolute maximum ratings of the V_{IN} and BOOST pins and by the minimum duty cycle $DC_{MIN} = 0.08$ (corresponding to a minimum on time of 130ns):

$$V_{IN(MAX)} = (V_{OUT} + V_D)/DC_{MIN} - V_D + V_{SW}$$

Note that this is a restriction on the operating input voltage; the circuit will tolerate transient inputs up to the absolute maximum ratings of the V_{IN} and BOOST pins.

Inductor Selection and Maximum Output Current

A good first choice for the inductor value is:

$$L = 5 (V_{OUT} + V_D)$$

where V_D is the voltage drop of the catch diode ($\sim 0.4V$) and L is in μH . With this value the maximum load current will be above 500mA. The inductor's RMS current rating must be greater than your maximum load current and its

APPLICATIONS INFORMATION

saturation current should be about 30% higher. For robust operation in fault conditions the saturation current should be ~1A. To keep efficiency high, the series resistance (DCR) should be less than 0.2Ω. Table 1 lists several vendors and types that are suitable.

Of course, such a simple design guide will not always result in the optimum inductor for your application. A larger value provides a slightly higher maximum load current, and will reduce the output voltage ripple. If your load is lower than 500mA, then you can decrease the value of the inductor and operate with higher ripple current. This allows you to use a physically smaller inductor, or one with a lower DCR resulting in higher efficiency. There are several graphs in the Typical Performance Characteristics section of this data sheet that show the maximum load current as a function of input voltage and inductor value for several popular output voltages. Low inductance may result in discontinuous mode operation, which is OK, but further reduces maximum load current. For details of maximum output current and discontinuous mode operation, see Linear Technology Application Note 44. Finally, for duty cycles greater than 50% ($V_{OUT}/V_{IN} > 0.5$), there is a minimum inductance required to avoid subharmonic oscillations. Choosing L greater than $3(V_{OUT} + V_D) \mu\text{H}$ prevents subharmonic oscillations at all duty cycles.

Catch Diode

A 0.5A or 1A Schottky diode is recommended for the catch diode, D1. The diode must have a reverse voltage rating equal to or greater than the maximum input voltage. The ON Semiconductor MBR0540 is a good choice; it is rated for 0.5A forward current and a maximum reverse voltage of 40V. The MBRM140 provides better efficiency, and will handle extended overload conditions.

Input Capacitor

Bypass the input of the LT1933 circuit with a 2.2μF or higher value ceramic capacitor of X7R or X5R type. Y5V types have poor performance over temperature and applied voltage, and should not be used. A 2.2μF ceramic is adequate to bypass the LT1933 and will easily handle the ripple current. However, if the input power source has high impedance, or there is significant inductance due to long wires or cables, additional bulk capacitance may be necessary. This can be provided with a low performance electrolytic capacitor.

Step-down regulators draw current from the input supply in pulses with very fast rise and fall times. The input capacitor is required to reduce the resulting voltage ripple at the LT1933 and to force this very high frequency

APPLICATIONS INFORMATION

switching current into a tight local loop, minimizing EMI. A 2.2µF capacitor is capable of this task, but only if it is placed close to the LT1933 and the catch diode; see the PCB Layout section. A second precaution regarding the ceramic input capacitor concerns the maximum input voltage rating of the LT1933. A ceramic input capacitor combined with trace or cable inductance forms a high quality (under damped) tank circuit. If the LT1933 circuit is plugged into a live supply, the input voltage can ring to twice its nominal value, possibly exceeding the LT1933's voltage rating. This situation is easily avoided; see the Hot Plugging Safely section.

Output Capacitor

The output capacitor has two essential functions. Along with the inductor, it filters the square wave generated by the LT1933 to produce the DC output. In this role it determines the output ripple, and low impedance at the switching frequency is important. The second function is to store energy in order to satisfy transient loads and stabilize the LT1933's control loop.

Ceramic capacitors have very low equivalent series resistance (ESR) and provide the best ripple performance. A good value is

$$C_{OUT} = 60/V_{OUT}$$

where C_{OUT} is in µF. Use X5R or X7R types, and keep in mind that a ceramic capacitor biased with V_{OUT} will have less than its nominal capacitance. This choice will provide low output ripple and good transient response. Transient performance can be improved with a high value capacitor, but a phase lead capacitor across the feedback resistor R1 may be required to get the full benefit (see the Compensation section).

High performance electrolytic capacitors can be used for the output capacitor. Low ESR is important, so choose one that is intended for use in switching regulators. The ESR should be specified by the supplier, and should be 0.1Ω or less. Such a capacitor will be larger than a ceramic capacitor and will have a larger capacitance, because the capacitor must be large to achieve low ESR. Table 2 lists several capacitor vendors.

APPLICATIONS INFORMATION

Figure 1 shows the transient response of the LT1933 with several output capacitor choices. The output is 3.3V. The load current is stepped from 100mA to 400mA and back to 100mA, and the oscilloscope traces show the output voltage. The upper photo shows the recommended value. The second photo shows the improved response (less voltage

drop) resulting from a larger output capacitor and a phase lead capacitor. The last photo shows the response to a high performance electrolytic capacitor. Transient performance is improved due to the large output capacitance, but output ripple (as shown by the broad trace) has increased because of the higher ESR of this capacitor.

Figure 1. Transient Load Response of the LT1933 with Different Output Capacitors as the Load Current is Stepped from 100mA to 400mA. $V_{IN} = 12V$, $V_{OUT} = 3.3V$, $L = 22\mu H$.

APPLICATIONS INFORMATION

BOOST Pin Considerations

Capacitor C3 and diode D2 are used to generate a boost voltage that is higher than the input voltage. In most cases a 0.1µF capacitor and fast switching diode (such as the 1N4148 or 1N914) will work well. Figure 2 shows two ways to arrange the boost circuit. The BOOST pin must be at least 2.3V above the SW pin for best efficiency. For outputs of 3V and above, the standard circuit (Figure 2a) is best. For outputs between 2.5V and 3V, use a 0.47µF capacitor and a small Schottky diode (such as the BAT-54). For lower output voltages the boost diode can be tied to the input (Figure 2b). The circuit in Figure 2a is more efficient because the BOOST pin current comes from a lower voltage source. You must also be sure that the maximum voltage rating of the BOOST pin is not exceeded.

The minimum operating voltage of an LT1933 application is limited by the undervoltage lockout (~3.35V) and by the maximum duty cycle as outlined above. For proper startup, the minimum input voltage is also limited by the boost circuit. If the input voltage is ramped slowly, or the LT1933 is turned on with its $\overline{\text{SHDN}}$ pin when the output is already in regulation, then the boost capacitor may not be fully charged. Because the boost capacitor is charged with the energy stored in the inductor, the circuit will rely on some minimum load current to get the boost circuit running properly. This minimum load will depend on input and output voltages, and on the arrangement of the boost circuit. The minimum load generally goes to zero once the circuit has started. Figure 3 shows a plot of minimum load to start and to run as a function of input voltage. In many

Figure 2. Two Circuits for Generating the Boost Voltage

Figure 3. The Minimum Input Voltage Depends on Output Voltage, Load Current and Boost Circuit

APPLICATIONS INFORMATION

cases the discharged output capacitor will present a load to the switcher which will allow it to start. The plots show the worst-case situation where V_{IN} is ramping very slowly. For lower start-up voltage, the boost diode can be tied to V_{IN} ; however, this restricts the input range to one-half of the absolute maximum rating of the BOOST pin.

At light loads, the inductor current becomes discontinuous and the effective duty cycle can be very high. This reduces the minimum input voltage to approximately 300mV above V_{OUT} . At higher load currents, the inductor current is continuous and the duty cycle is limited by the maximum duty cycle of the LT1933, requiring a higher input voltage to maintain regulation.

Soft-Start

The $\overline{\text{SHDN}}$ pin can be used to soft-start the LT1933, reducing the maximum input current during start up. The $\overline{\text{SHDN}}$ pin is driven through an external RC filter to create a voltage ramp at this pin. Figure 4 shows the start up waveforms with and without the soft-start circuit. By choosing a large RC time constant, the peak start up current can be reduced to the current that is required to regulate the output, with no overshoot. Choose the value of the resistor so that it can supply 60 μA when the $\overline{\text{SHDN}}$ pin reaches 2.3V.

Figure 4. To Soft-Start the LT1933, Add a Resistor and Capacitor to the SHDN Pin. $V_{IN1} = 12\text{V}$, $V_{OUT} = 3.3\text{V}$, $C_{OUT} = 22\mu\text{F}$, $R_{LOAD} = 10\Omega$

(6b)

(6c)

Figure 6. A Well Chosen Input Network Prevents Input Voltage Overshoot and Ensures Reliable Operation When the LT1933 is Connected to a Live Supply

APPLICATIONS INFORMATION

Figure 6 shows the waveforms that result when an LT1933 circuit is connected to a 24V supply through six feet of 24-gauge twisted pair. The first plot is the response with a 2.2 μ F ceramic capacitor at the input. The input voltage rings as high as 35V and the input current peaks at 20A. One method of damping the tank circuit is to add another capacitor with a series resistor to the circuit. In Figure 6b an aluminum electrolytic capacitor has been added. This capacitor's high equivalent series resistance damps the circuit and eliminates the voltage overshoot. The extra capacitor improves low frequency ripple filtering and can slightly improve the efficiency of the circuit, though it is likely to be the largest component in the circuit. An alternative solution is shown in Figure 6c. A 1 Ω resistor is added in series with the input to eliminate the voltage overshoot (it also reduces the peak input current). A 0.1 μ F capacitor improves high frequency filtering. This solution is smaller and less expensive than the electrolytic capacitor. For high input voltages its impact on efficiency is minor, reducing efficiency less than one half percent for a 5V output at full load operating from 24V.

Frequency Compensation

The LT1933 uses current mode control to regulate the output. This simplifies loop compensation. In particular, the LT1933 does not require the ESR of the output capacitor for stability allowing the use of ceramic capacitors to achieve low output ripple and small circuit size.

Figure 7 shows an equivalent circuit for the LT1933 control loop. The error amp is a transconductance amplifier with finite output impedance. The power section, consisting of the modulator, power switch and inductor, is modeled as a transconductance amplifier generating an output current proportional to the voltage at the V_C node. Note that the output capacitor integrates this current, and that the capacitor on the V_C node (C_C) integrates the error amplifier output current, resulting in two poles in the loop. R_C provides a zero. With the recommended output capacitor, the loop crossover occurs above the $R_C C_C$ zero. This simple model works well as long as the value of the inductor is not too high and the loop crossover frequency is much lower than the switching frequency. With a larger ceramic capacitor (very low ESR), crossover may be lower and a phase lead capacitor (C_{PL}) across the feedback divider may improve the phase margin and transient response. Large electrolytic capacitors may have an ESR large enough to create an additional zero, and the phase lead may not be necessary.

If the output capacitor is different than the recommended capacitor, stability should be checked across all operating conditions, including load current, input voltage and temperature. The LT1375 data sheet contains a more thorough discussion of loop compensation and describes how to test the stability using a transient load.

Figure 7. Model for Loop Response

APPLICATIONS INFORMATION

PCB Layout

For proper operation and minimum EMI, care must be taken during printed circuit board layout. Figure 8 shows the recommended component placement with trace, ground plane and via locations. Note that large, switched currents flow in the LT1933's V_{IN} and SW pins, the catch diode (D1) and the input capacitor (C2). The loop formed by these components should be as small as possible and tied to system ground in only one place. These components, along with the inductor and output capacitor, should be placed on the same side of the circuit board, and their connections should be made on that layer. Place a local,

unbroken ground plane below these components, and tie this ground plane to system ground at one location, ideally at the ground terminal of the output capacitor C1. The SW and BOOST nodes should be as small as possible. Finally, keep the FB node small so that the ground pin and ground traces will shield it from the SW and BOOST nodes. Include two vias near the GND pin of the LT1933 to help remove heat from the LT1933 to the ground plane.

Figure 8a shows the layout for the DFN package. Vias near and under the exposed die attach paddle minimize the thermal resistance of the LT1933.

LT1676	60V, 440mA I_{OUT} , 100kHz, High Efficiency Step-Down DC/DC Converter	V_{IN} : 7.4V to 60V, $V_{OUT(MIN)}$ = 1.24V, I_Q = 3.2mA, I_{SD} = 2.5µA, S8 Package
LT1765	25V, 2.75mA I_{OUT} , 1.25MHz, High Efficiency Step-Down DC/DC Converter	V_{IN} : 3V to 25V, $V_{OUT(MIN)}$ = 1.2V, I_Q = 1mA, I_{SD} = 15µA, S8, TSSOP16E Packages
LT1766	60V, 1.2A I_{OUT} , 200kHz, High Efficiency Step-Down DC/DC Converter	V_{IN} : 5.5V to 60V, $V_{OUT(MIN)}$ = 1.2V, I_Q = 2.5mA, I_{SD} = 25µA, S8, TSSOP16/TSSOP16E Packages
LT1767	25V, 1.2A I_{OUT} , 1.25MHz, High Efficiency Step-Down DC/DC Converter	V_{IN} : 3V to 25V, $V_{OUT(MIN)}$ = 1.2V, I_Q = 1mA, I_{SD} = 6µA, S8, MS8/MS8E Packages
LT1776	40V, 550mA I_{OUT} , 200kHz, High Efficiency Step-Down DC/DC Converter	V_{IN} : 7.4V to 40V, $V_{OUT(MIN)}$ = 1.24V, I_Q = 3.2mA, I_{SD} = 30µA, S8, N8, S8 Packages
LT1940	25V, Dual 1.4A I_{OUT} , 1.1MHz, High Efficiency Step-Down DC/DC Converter	V_{IN} : 3.6V to 25V, $V_{OUT(MIN)}$ = 1.25V, I_Q = 3.8mA, I_{SD} < 30µA, TSSOP16E Package
LT1956	60V, Dual 1.2A I_{OUT} , 500kHz, High Efficiency Step-Down DC/DC Converter	V_{IN} : 5.5V to 60V, $V_{OUT(MIN)}$ = 1.2V, I_Q = 2.5mA, I_{SD} = 25µA, TSSOP16/TSSOP16E Packages
LT1976	60V, Dual 1.2A I_{OUT} , 200kHz, High Efficiency Step-Down DC/DC Converter with Burst Mode®	V_{IN} : 3.3V to 60V, $V_{OUT(MIN)}$ = 1.2V, I_Q = 100µA, I_{SD} < 1µA, TSSOP16E Package
LT3010	80V, 50mA, Low Noise Linear Regulator	V_{IN} : 1.5V to 80V, $V_{OUT(MIN)}$ = 1.28V, I_Q = 30µA, I_{SD} < 1µA, MS8E Package
LT3407	Dual 600mA I_{OUT} , 1.5MHz, Synchronous Step-Down DC/DC Converter	V_{IN} : 2.5V to 5.5V, $V_{OUT(MIN)}$ = 0.6V, I_Q = 40µA, I_{SD} < 1µA, MS10E Package
LT3412	2.5A I_{OUT} , 4MHz, Synchronous Step-Down DC/DC Converter	V_{IN} : 2.5V to 5.5V, $V_{OUT(MIN)}$ = 0.8V, I_Q = 60µA, I_{SD} < 1µA, TSSOP16E Package
LTC3414	4A I_{OUT} , 4MHz, Synchronous Step-Down DC/DC Converter	V_{IN} : 2.3V to 5.5V, $V_{OUT(MIN)}$ = 0.8V, I_Q = 64µA, I_{SD} < 1µA, TSSOP20E Package
LT3430/LT3431	60V, 2.75A I_{OUT} , 200kHz/500kHz, Synchronous Step-Down DC/DC Converter	V_{IN} : 5.5V to 60V, $V_{OUT(MIN)}$ = 1.2V, I_Q = 2.5mA, I_{SD} = 30µA, TSSOP16E Package
