

## 1 Overview

### 1.1 Features

- Three Half-Bridges
- Optimized for DC motor management applications
- Delivers up to 0.6 A continuous, 1.2 A peak current
- $R_{DS\ ON}$ ; typ. 0.8  $\Omega$ , @ 25 °C per switch
- Output: short circuit protected and diagnosis
- Overtemperature-Protection with hysteresis and diagnosis
- Standard SPI-Interface/Daisy chain capable
- Very low current consumption in stand-by (Inhibit) mode (typ. 10  $\mu$ A for power and 2  $\mu$ A for logic supply, @ 25 °C)
- Over- and Undervoltage-Lockout
- CMOS/TTL compatible inputs with hysteresis
- No crossover current
- Internal clamp diodes
- Enhanced power P-DSO-Package
- Programming compatibility to the TLE 5208-6
- Green Product (RoHS compliant)
- AEC Qualified

Type	Package
TLE 6208-3 G	PG-DSO-14-35

### Functional Description

The TLE 6208-3 G is a fully protected **Triple-Half-Bridge-Driver** designed specifically for automotive and industrial motion control applications. The part is based on the Siemens power technology SPT<sup>®</sup> which allows bipolar and CMOS control circuitry in accordance with DMOS power devices existing on the same monolithic circuitry.

In motion control up to 2 actuators (DC-Motors) can be connected to the 3 halfbridge-outputs (cascade configuration). Operation modes forward (cw), reverse (ccw), brake and high impedance are controlled from a standard SPI-Interface. The possibility to control the outputs via software from a central logic, allows limiting the power dissipation. So the standard P-DSO-14-package meets the application requirements and saves PCB-Board-space and cost. Furthermore the build-in features like Over- and Undervoltage-Lockout, Over-Temperature-Protection and the very low quiescent current in stand-by mode opens a wide range of automotive- and industrial-applications.

### 1.3 Pin Definitions and Functions

Pin No.	Symbol	Function
1	GND	<b>Ground;</b> Reference potential; internal connection to pin 7, 8 and 14; cooling tab; to reduce thermal resistance place cooling areas on PCB close to these pins.
2	OUT3	<b>Halfbridge-Output 3;</b> Internally connected to Highside-Switch 3 and Lowside-Switch 3. The HS-Switch is a Power-MOS open drain with internal reverse diode; The LS-Switch is a Power-MOS open source with internal reverse diode; no internal clamp diode or active zenering; short circuit protected and open load controlled.
3	$V_S$	<b>Power Supply;</b> needs a blocking capacitor as close as possible to GND Value: 22 $\mu$ F electrolytic in parallel to 220 nF ceramic.
5	DI	<b>Serial Data Input;</b> receives serial data from the control device; serial data transmitted to DI is an 16bit control word with the Least Significant Bit (LSB) being transferred first: the input has an active pull down and requires CMOS logic level inputs; DI will accept data on the falling edge of CLK-signal; see <b>Table Input Data Protocol</b> .
4	CSN	<b>Chip-Select-Not Input;</b> CSN is an active low input; serial communication is enabled by pulling the CSN terminal low; CSN input should only be transitioned when CLK is low; CSN has an internal active pull up and requires CMOS logic level inputs.
6	CLK	<b>Serial Clock Input;</b> clocks the shiftregister; CLK has an internal active pull down and requires CMOS logic level inputs.
7, 8, 14	GND	<b>Ground;</b> see pin 1.
9	DO	<b>Serial-Data-Output;</b> this 3-state output transfers diagnosis data to the control device; the output will remain 3-stated unless the device is selected by a low on Chip-Select-Not (CSN); see <b>Table Diagnosis Data Protocol</b> .
10	INH	<b>Inhibit Input;</b> has an internal pull down; device is switched in standby condition by pulling the INH terminal low.
11	$V_{CC}$	<b>Logic Supply Voltage;</b> needs a blocking capacitor as close as possible to GND; Value: 10 $\mu$ F electrolytic in parallel to 220 nF ceramic.
12	OUT2	<b>Halfbridge-Output 2;</b> see pin 2.
13	OUT1	<b>Halfbridge-Output 1;</b> see pin 2.

## 1.5 Circuit Description

**Figure 2** shows a block schematic diagram of the module. There are 3 halfbridge drivers on the right-hand side. An HS driver and an LS driver are combined to form a halfbridge driver in each case. The drivers communicate via the internal data bus with the logic and the other control and monitoring functions: undervoltage (UV), overvoltage (OV), overtemperature (TSD), charge pump and fault detect.

Two connection interfaces are provided for supply to the module: All power drivers are connected to the supply voltage  $V_S$ . These are monitored by overvoltage and undervoltage comparators with hysteresis, so that the correct function can be checked in the application at any time.

The logic is supplied by the  $V_{CC}$  voltage, typ. with 5 V. The  $V_{CC}$  voltage uses an internally generated Power-On Reset (POR) to initialize the module at power-on. The advantage of this system is that information stored in the logic remains intact in the event of short-term failures in the supply voltage  $V_S$ . The system can therefore continue to operate following  $V_S$  undervoltage, without having to be reprogrammed. The “undervoltage” information is stored, and can be read out via the interface. The same logically applies for overvoltage. “Interference spikes” on  $V_S$  are therefore effectively suppressed.

The situation is different in the case of undervoltage on the  $V_{CC}$  connection pin. If this occurs, then the internally stored data is deleted, and the output levels are switched to high-impedance status (tristate). The module is initialized by  $V_{CC}$  following restart (Power-On Reset = POR).

The 16-bit wide programming word or control word (see **Table Input Data Protocol**) is read in via the DI data input, and this is synchronized with the clock input CLK. The status word appears synchronously at the DO data output (see **Table Diagnosis Data Protocol**). It is also possible to connect two **TLE 6208-3 G** in a daisy chain configuration. The DO data output of one device is connected with the DI data input of the second device. In this configuration these two devices are controlled with a single CSN chip select and using a 32-bit wide control word.

The transmission cycle begins when the chip is selected with the CSN input (H to L). If the CSN input changes from L to H then the word which has been read in becomes the control word. The DO output switches to tristate status at this point, thereby releasing the DO bus circuit for other uses.

The INH inhibit input can be used to cut off the complete module. This reduces the current consumption to just a few  $\mu\text{A}$ , and results in the loss of any data stored. The output levels are switched to tristate status. The module is reinitialized with the internally generated POR (Power-On Reset) at restart.

This feature allows the use of this module in battery-operated applications (vehicle body control applications).

Every driver block from DRV 1 to 3 contains a low-side driver and a high-side driver. Both drivers are connected internally to form a half-bridge at the output. This reduction of output pins was necessary to meet the small P-DSO-14 package.

When commutating inductive loads, the dissipated power peak can be significantly reduced by activating the transistor located parallel to the internal freewheeling diode. A special, integrated "timer" for power ON/OFF times ensures that there is no crossover current.
