FM3104/16/64/256

Integrated Processor Companion with Memory

RAMTRON

Features

High Integration Device Replaces Multiple Parts

- Serial Nonvolatile Memory
- Real-time Clock (RTC)
- Low Voltage Reset
- Watchdog Timer
- Early Power-Fail Warning/NMI
- Two 16-bit Event Counters
- Serial Number with Write-lock for Security

Ferroelectric Nonvolatile RAM

- 4Kb, 16Kb, 64Kb, and 256Kb versions
- Unlimited Read/Write Endurance
- 10 year Data Retention
- NoDelayTM Writes

Real-time Clock/Calendar

- Backup Current under 1 µA
- Seconds through Centuries in BCD format
- Tracks Leap Years through 2099
- Uses Standard 32.768 kHz Crystal (6pF)
- Software Calibration
- Supports Battery or Capacitor Backup

Processor Companion

- Active-low Reset Output for V_{DD} and Watchdog
- Programmable V_{DD} Reset Trip Point
- Manual Reset Filtered and Debounced
- Programmable Watchdog Timer
- Dual Battery-backed Event Counter Tracks System Intrusions or other Events
- Comparator for Early Power-Fail Interrupt
- 64-bit Programmable Serial Number with Lock

Fast Two-wire Serial Interface

- Up to 1 MHz Maximum Bus Frequency
- Supports Legacy Timing for 100 kHz & 400 kHz
- Device Select Pins for up to 4 Memory Devices
- RTC, Supervisor Controlled via 2-wire Interface

Easy to Use Configurations

- Operates from 2.7 to 5.5V
- Small Footprint 14-pin "Green" SOIC (-G)
- Low Operating Current
- -40°C to +85°C Operation

Description

The FM31xx is a family of integrated devices that includes the most commonly needed functions for processor-based systems. Major features include nonvolatile memory available in various sizes, realtime clock, low-VDD reset, watchdog timer, nonvolatile event counter, lockable 64-bit serial number area, and general purpose comparator that can be used for an early power-fail (NMI) interrupt or other purpose. The family operates from 2.7 to 5.5V.

Each FM31xx provides nonvolatile RAM available in sizes including 4Kb, 16Kb, 64Kb, and 256Kb versions. Fast write speed and unlimited endurance allow the memory to serve as extra RAM or conventional nonvolatile storage. This memory is truly nonvolatile rather than battery backed.

The real-time clock (RTC) provides time and date information in BCD format. It can be permanently powered from external backup voltage source, either a battery or a capacitor. The timekeeper uses a common external 32.768 kHz crystal and provides a calibration mode that allows software adjustment of timekeeping accuracy.

The processor companion includes commonly needed CPU support functions. Supervisory functions include a reset output signal controlled by either a low VDD condition or a watchdog timeout. /RST goes active when VDD drops below a programmable threshold and remains active for 100 ms after VDD rises above the trip point. A programmable watchdog timer runs from 100 ms to 3 seconds. The watchdog timer is optional, but if enabled it will assert the reset signal for 100 ms if not restarted by the host before the timeout. A flag-bit indicates the source of the reset.

A general-purpose comparator compares an external input pin to the onboard 1.2V reference. This is useful for generating a power-fail interrupt (NMI) but can be used for any purpose. The family also includes a programmable 64-bit serial number that can be locked making it unalterable. Additionally it offers a dual battery-backed event counter that tracks the number of rising or falling edges detected on dedicated input pins.

This is a product in pre-production phase of development. Device characterization is complete and Ramtron does not expect to change the specifications. Ramtron will issue a Product Change Notice if any specification changes are made.

Pin Configuration

Pin Name	Function
CNT1, CNT2	Event Counter Inputs
A0, A1	Device Select inputs
CAL/PFO	Clock Calibration and Early
	Power-Fail Output
/RST	Reset Input/Output
PFI	Early Power-fail Input
X1, X2	Crystal Connections
SDA	Serial Data
SCL	Serial Clock
VBAK	Battery-Backup Supply
VDD	Supply Voltage
VSS	Ground

Ordering Information							
Base Configuration	Memory Size	Operating Voltage	Reset Threshold	Ordering Part Number			
FM31256	256Kb	2.7-5.5V	2.6V, 2.9, 3.9, 4.4V	FM31256-G			
FM3164	64Kb	2.7-5.5V	2.6V, 2.9, 3.9, 4.4V	FM3164-G			
FM3116	16Kb	2.7-5.5V	2.6V, 2.9, 3.9, 4.4V	FM3116-G			
FM3104	4Kb	2.7-5.5V	2.6V, 2.9, 3.9, 4.4V	FM3104-G			

Other memory configurations may be available. Please contact the factory for more information.

Figure 1. Block Diagram

Pin Descriptions

Pin Name	Type	Pin Description
A0, A1	Input	Device select inputs are used to address multiple memories on a serial bus. To select the device the address value on the two pins must match the corresponding bits contained in the device address. The device select pins are pulled down internally.
CNT1, CNT2	Input	Event Counter Inputs: These battery-backed inputs increment counters when an edge is detected on the corresponding CNT pin. The polarity is programmable. These pins should not be left floating. Tie to ground if pins are not used.
CAL/PFO	Output	In calibration mode, this pin supplies a 512 Hz square-wave output for clock calibration. In normal operation, this is the early power-fail output.
X1, X2	I/O	32.768 kHz crystal connection. When using an external oscillator, apply the clock to X1 and leave X2 floating.
/RST	I/O	Active low reset output with weak pull-up. Also input for manual reset.
SDA	I/O	Serial Data & Address: This is a bi-directional line for the two-wire interface. It is open-drain and is intended to be wire-OR'd with other devices on the two-wire bus. The input buffer incorporates a Schmitt trigger for noise immunity and the output driver includes slope control for falling edges. A pull-up resistor is required.
SCL	Input	Serial Clock: The serial clock line for the two-wire interface. Data is clocked out of the part on the falling edge, and in on the rising edge. The SCL input also incorporates a Schmitt trigger input for noise immunity.
PFI	Input	Early Power-fail Input: Typically connected to an unregulated power supply to detect an early power failure. This pin should not be left floating.
VBAK	Supply	Backup supply voltage: A 3V battery or a large value capacitor. If V_{DD} <3.6V and no backup supply is used, this pin should be tied to V_{DD} . If V_{DD} >3.6V and no backup supply is used, this pin should be left floating and the VBC bit should be set.
VDD	Supply	Supply Voltage.
VSS	Supply	Ground

Overview

The FM31xx family combines a serial nonvolatile RAM with a real-time clock (RTC) and a processor companion. The companion is a highly integrated peripheral including a processor supervisor, a comparator used for early power-fail warning, nonvolatile event counters, and a 64-bit serial number. The FM31xx integrates complementary but distinct functions that share a common interface in a single package. Although monolithic, the product is organized as two logical devices. the **FRAM** memory and RTC/companion. From the system perspective they appear to be two separate devices with unique IDs on the serial bus.

The memory is organized as a stand-alone 2-wire nonvolatile memory with a standard device ID value. The real-time clock and supervisor functions are accessed with a separate 2-wire device ID. This allows clock/calendar data to be read while maintaining the most recently used memory address. The clock and supervisor functions are controlled by 25 special function registers. The RTC and event counter circuits are maintained by the power source on the VBAK pin, allowing them to operate from battery or backup capacitor power when $V_{\rm DD}$ drops below an internally set threshold. Each functional block is described below.

Memory Operation

The FM31xx is a family of products available in different memory sizes including 4Kb, 16Kb, 64Kb, and 256Kb. The family is software compatible, all versions use consistent two-byte addressing for the memory device. This makes the lowest density device different from its stand-alone memory counterparts but makes them compatible within the entire family.

Memory is organized in bytes, for example the 4Kb memory is 512 x 8 and the 256Kb memory is 32,768 x 8. The memory is based on FRAM technology. Therefore it can be treated as RAM and is read or written at the speed of the two-wire bus with no delays for write operations. It also offers effectively unlimited write endurance unlike other nonvolatile memory technologies. The 2-wire interface protocol is described further on page 13.

The memory array can be write-protected by software. Two bits in the processor companion area (WP0, WP1 in register 0Bh) control the protection setting as shown in the following table. Based on the setting, the protected addresses cannot be written and the 2-wire interface will not acknowledge any data to

protected addresses. The special function registers containing these bits are described in detail below.

Write protect addresses	WP1	WP0
None	0	0
Bottom 1/4	0	1
Bottom 1/2	1	0
Full array	1	1

Processor Companion

In addition to nonvolatile RAM, the FM31xx family incorporates a highly integrated processor companion. It includes a low voltage reset, a programmable watchdog timer, battery-backed event counters, a comparator for early power-fail detection or other purposes, and a 64-bit serial number.

Processor Supervisor

Supervisors provide a host processor two basic functions: detection of power supply fault conditions and a watchdog timer to escape a software lockup condition. All FM31xx devices have a reset pin (/RST) to drive the processor reset input during power faults (and power-up) and software lockups. It is an open drain output with a weak internal pull-up to V_{DD}. This allows other reset sources to be wire-OR'd to the /RST pin. When V_{DD} is above the programmed trip point, /RST output is pulled weakly to V_{DD}. If V_{DD} drops below the reset trip point voltage level (V_{TP}) the /RST pin will be driven low. It will remain low until V_{DD} falls too low for circuit operation which is the V_{RST} level. When V_{DD} rises again above V_{TP}, /RST will continue to drive low for at least 100 ms (t_{RPU}) to ensure a robust system reset at a reliable V_{DD} level. After t_{RPU} has been met, the /RST pin will return to the weak high state. While /RST is asserted, serial bus activity is locked out even if a transaction occurred as V_{DD} dropped below V_{TP} . A memory operation started while V_{DD} is above V_{TP} will be completed internally.

Figure 2 below illustrates the reset operation in response to the $V_{\rm DD}$ voltage.

Figure 2. Low Voltage Reset

The bits VTP1 and VTP0 control the trip point of the low voltage detect circuit. They are located in register 0Bh, bits 1 and 0.

V_{TP}	VTP1	VTP0
$2.\overline{6}V$	0	0
2.9V	0	1
3.9V	1	0
4.4V	1	1

The watchdog timer can also be used to assert the reset signal (/RST). The watchdog is a free running programmable timer. The period can be software programmed from 100 ms to 3 seconds in 100 ms increments via a 5-bit nonvolatile register. All programmed settings are minimum values and vary with temperature according to the operating specifications. The watchdog has two additional controls associated with its operation, a watchdog enable bit (WDE) and timer restart bits (WR). Both the enable bit must be set and the watchdog must timeout in order to drive /RST active. If a reset event occurs, the timer will automatically restart on the rising edge of the reset pulse. If not enabled, the watchdog timer runs but has no effect on /RST. Note that setting the maximum timeout setting (11111b) disables the counter to save power. The second control is a nibble that restarts the timer preventing a reset. The timer should be restarted after changing the timeout value.

The watchdog timeout value is located in register 0Ah, bits 4-0, and the watchdog enable is bit 7. The watchdog is restarted by writing the pattern 1010b to the lower nibble of register 09h. Writing this pattern will also cause the timer to load new timeout values. Writing other patterns to this address will not affect its operation. Note the watchdog timer is freerunning. Prior to enabling it, users should restart the timer as described above. This assures that the full timeout period will be set immediately after enabling. The watchdog is disabled when V_{DD} is below V_{TP} . The following table summarizes the watchdog bits. A block diagram follows.

Watchdog timeout WDT4-0 0Ah, bits 4-0 Watchdog enable WDE 0Ah, bit 7 Watchdog restart WR3-0 09h, bits 3-0

Figure 3. Watchdog Timer

Manual Reset

The /RST pin is bi-directional and allows the FM31xx to filter and de-bounce a manual reset switch. The /RST input detects an external low condition and responds by driving the /RST signal low for 100 ms.

Figure 4. Manual Reset

Note that an internal weak pull-up on /RST eliminates the need for additional external components.

Reset Flags

In case of a reset condition, a flag will be set to indicate the source of the reset. A low $V_{\rm DD}$ reset or manual reset is indicated by the POR flag, register 09h bit 6. A watchdog reset is indicated by the WTR flag, register 09h bit 7. Note that the flags are internally set in response to reset sources, but they must be cleared by the user. When the register is read, it is possible that both flags are set if both have occurred since the user last cleared them.

Early Power Fail Comparator

An early power fail warning can be provided to the processor well before $V_{\rm DD}$ drops out of spec. The comparator is used to create a power fail interrupt (NMI). This can be accomplished by connecting the PFI pin to the unregulated power supply via a resistor divider. An application circuit is shown below.

Figure 5. Comparator as Early Power-Fail Warning

The voltage on the PFI input pin is compared to an onboard 1.2V reference. When the PFI input voltage drops below this threshold, the comparator will drive the CAL/PFO pin to a low state. The comparator has 100 mV (max) of hysteresis to reduce noise sensitivity, only for a rising PFI signal. For a falling PFI edge, there is no hysteresis.

The comparator is a general purpose device and its application is not limited to the NMI function.

The comparator is not integrated into the special function registers except as it shares its output pin with the CAL output. When the RTC calibration mode is invoked by setting the CAL bit (register 00h, bit 2), the CAL/PFO output pin will be driven with a 512 Hz square wave and the comparator will be ignored. Since most users only invoke the calibration mode during production, this should have no impact on system operations using the comparator.

Note: The maximum voltage on the comparator input PFI is limited to 3.75V under normal operating conditions.

Event Counter

The FM31xx offers the user two battery-backed event counters. Input pins CNT1 and CNT2 are programmable edge detectors. Each clocks a 16-bit counter. When an edge occurs, the counters will increment their respective registers. Counter 1 is located in registers 0Dh and 0Eh, Counter 2 is located in registers 0Fh and 10h. These register values can be read anytime VDD is above VTP, and they will be incremented as long as a valid VBAK power source is provided. To read, set the RC bit register 0Ch bit 3 to 1. This takes a snapshot of all four counter bytes allowing a stable value even if a count occurs during the read. The registers can be written by software allowing the counters to be cleared or initialized by the system. Counts are blocked during a write operation. The two counters can be cascaded to create a single 32-bit counter by setting the CC control bit (register 0Ch). When cascaded, the CNT1 input will cause the counter to increment. CNT2 is not used in this mode.

Figure 6. Event Counter

The control bits for event counting are located in register 0Ch. Counter 1 Polarity is bit C1P, bit 0; Counter 2 Polarity is C2P, bit 1; the Cascade Control is CC, bit 2; and the Read Counter bit is RC bit 3.

The polarity bits must be set prior to setting the counter value(s). If a polarity bit is changed, the counter may inadvertently increment. If the counter pins are not being used, tie them to ground.

Serial Number

A memory location to write a 64-bit serial number is provided. It is a writeable nonvolatile memory block that can be locked by the user once the serial number is set. The 8 bytes of data and the lock bit are all accessed via the device ID for the processor companion. Therefore the serial number area is separate and distinct from the memory array. The serial number registers can be written an unlimited number of times, so these locations are general purpose memory. However once the lock bit is set the values cannot be altered and the lock cannot be removed. Once locked the serial number registers can still be read by the system.

The serial number is located in registers 11h to 18h. The lock bit is SNL, register 0Bh bit 7. Setting the SNL bit to a 1 disables writes to the serial number registers, and *the SNL bit cannot be cleared*.

Real-Time Clock Operation

The real-time clock (RTC) is a timekeeping device that can be battery or capacitor backed for permanently-powered operation. It offers a software calibration feature that allows high accuracy.

The RTC consists of an oscillator, clock divider, and a register system for user access. It divides down the 32.768 kHz time-base and provides a minimum resolution of seconds (1Hz). Static registers provide the user with read/write access to the time values. It includes registers for seconds, minutes, hours, day-of-the-week, date, months, and years. A block diagram (Figure 7) illustrates the RTC function.

The user registers are synchronized with the timekeeper core using R and W bits in register 00h described below. Changing the R bit from 0 to 1 transfers timekeeping information from the core into holding registers that can be read by the user. If a timekeeper update is pending when R is set, then the core will be updated prior to loading the user registers. The registers are frozen and will not be updated again until the R bit is cleared to 0. R is used for reading the time.

Setting the W bit to 1 locks the user registers. Clearing it to 0 causes the values in the user registers

to be loaded into the timekeeper core. W is used for writing new time values. Users should be certain not to load invalid values, such as FFh, to the timekeeping registers. Updates to the timekeeping core occur continuously except when locked.

Backup Power

The real-time clock/calendar is intended to be permanently powered. When the primary system power fails, the voltage on the V_{DD} pin will drop. When V_{DD} is less 2.5V the RTC (and event counters) will switch to the backup power supply on V_{BAK} . The clock operates at extremely low current in order to maximize battery or capacitor life. However, an advantage of combining a clock function with FRAM memory is that data is not lost regardless of the backup power source.

When inserting a battery into a system board, higher-than-normal battery drain may occur. It is recommended that your system power-up procedure complies with one of the following:

Scenario #1

- a) Apply Vdd to board.
- b) Insert battery. At this point, I_{BAK} is zero.
- c) When V_{DD} is powered down, the I_{BAK} current will be less than $1\mu A$.

Scenario #2

- a) Insert battery without power to board (V_{DD} is off). At this point, the I_{BAK} current may be much higher than the $1\mu A$ spec limit. An extended period of time (days) in this state could significantly reduce battery life.
- b) Apply V_{DD} to board. I_{BAK} goes to zero.

c) When V_{DD} is powered down, the I_{BAK} current will be less than $1\mu A$.

Trickle Charger

To facilitate capacitor backup the V_{BAK} pin can optionally provide a trickle charge current. When the VBC bit, register 0Bh bit 2, is set to 1 the V_{BAK} pin will source approximately 15 μ A until V_{BAK} reaches V_{DD} or 3.75V whichever is less. In 3V systems, this charges the capacitor to V_{DD} without an external diode and resistor charger. In 5V systems, it provides the same convenience and also prevents the user from exceeding the V_{BAK} maximum voltage specification.

In the case where no battery is used, the V_{BAK} pin should be tied according to the following conditions:

- For 3.3V systems, V_{BAK} should be tied to V_{DD}.
 This assumes V_{DD} does not exceed 3.75V.
- For 5V systems, attach a 1 μ F capacitor to V_{BAK} and turn the trickle charger on. The V_{BAK} pin will charge to the internal backup voltage which regulates itself to about 3.6V. V_{BAK} should not be tied to 5V since the V_{BAK} (max) specification will be exceeded. A 1 μ F capacitor will keep the companion functions working for about 1.5 second.

Although V_{BAK} may be connected to V_{SS} , this is not recommended if the companion is used. None of the companion functions will operate below about 2.5V.

 ${}^{\psi}$ Note: systems using lithium batteries should clear the VBC bit to 0 to prevent battery charging. The V_{BAK} circuitry includes an internal 1 $K\Omega$ series resistor as a safety element.

Figure 7. Real-Time Clock Core Block Diagram

Calibration

When the CAL bit in a register 00h is set to 1, the clock enters calibration mode. In calibration mode, the CAL/PFO output pin is dedicated to the calibration function and the power fail output is temporarily unavailable. Calibration operates by applying a digital correction to the counter based on the frequency error. In this mode, the CAL/PFO pin is driven with a 512 Hz (nominal) square wave. Any measured deviation from 512 Hz translates into a timekeeping error. The user converts the measured error in ppm and writes the appropriate correction value to the calibration register. The correction factors are listed in the table below. Positive ppm errors require a negative adjustment that removes pulses. Negative ppm errors require a positive correction that adds pulses. Positive ppm adjustments have the CALS (sign) bit set to 1, where as negative ppm adjustments have CALS = 0. After calibration, the clock will have a maximum error of \pm 2.17 ppm or ± 0.09 minutes per month at the calibrated temperature.

Layout for Surface Mount Crystal (red = top layer, green = bottom layer)

The calibration setting is stored in FRAM so is not lost should the backup source fail. It is accessed with bits CAL.4-0 in register 01h. This value only can be written when the CAL bit is set to a 1. To exit the calibration mode, the user must clear the CAL bit to a 0. When the CAL bit is 0, the CAL/PFO pin will revert to the power fail output function.

Layout Requirements

The X1 and X2 crystal pins employ very high impedance circuits and the oscillator connected to these pins can be upset by noise or extra loading. To reduce RTC clock errors from signal switching noise, a guard ring must be placed around these pads and the guard ring grounded. SDA and SCL traces should be routed away from the X1/X2 pads. The X1 and X2 trace lengths should be less than 5 mm. The use of a ground plane on the backside or inner board layer is preferred. See layout example. Red is the top layer, green is the bottom layer.

Layout for Through Hole Crystal (red = top layer, green = bottom layer)

Register Map

The RTC and processor companion functions are accessed via 25 special function registers mapped to a separate 2-wire device ID. The interface protocol is described below. The registers contain timekeeping data, control bits, or information flags. A description of each register follows the summary table below.

Register Map Summary Table

Nonvolatile = Battery-backed =

				Da	ata					
Address	D7	D6	D5	D4	D3	D2	D1	D0	Function	Range

	Reserved	CF	Reserved	Reserved	Reserved	CAL	W	R			
CF	Century Overflow Flag. This bit is set to a 1 when the values in the years register overflows from 99 to 00. This indicates a register overflow specific from 1000 to 2000 or 2000 to 2100. The year should record the pay.										
	century infor	indicates a new century, such as going from 1999 to 2000 or 2099 to 2100. The user should record the new century information as needed. This bit is cleared to 0 when the Flag register is read. It is read-only for the user. Battery-backed.									
CAL				enters calibrated by the power							
W	updated value	es. Resetting th	e W bit to 0 car	the clock. The uses the content. Battery-backe	ts of the time i						
R	Read Time. Setting the R bit to 1 copies a static image of the timekeeping core and place it into the user registers. The user can then read them without concerns over changing values causing system errors. The R bit going from 0 to 1 causes the timekeeping capture, so the bit must be returned to 0 prior to reading again. Battery-backed, read/write.										
Reserved	Reserved bits	. Do not use. S	hould remain s	et to 0.							

Two-wire Interface

The FM31xx employs an industry standard two-wire bus that is familiar to many users. This product is unique since it incorporates two logical devices in one chip. Each logical device can be accessed individually. Although monolithic, it appears to the system software to be two separate products. One is a memory device. It has a Slave Address (Slave ID = 1010b) that operates the same as a stand-alone memory device. The second device is a real-time clock and processor companion which have a unique Slave Address (Slave ID = 1101b).

By convention, any device that is sending data onto the bus is the transmitter while the target device for this data is the receiver. The device that is controlling the bus is the master. The master is responsible for generating the clock signal for all operations. Any device on the bus that is being controlled is a slave. The FM31xx is always a slave device.

The bus protocol is controlled by transition states in the SDA and SCL signals. There are four conditions: Start, Stop, Data bit, and Acknowledge. The figure below illustrates the signal conditions that specify the four states. Detailed timing diagrams are shown in the Electrical Specifications section.

Figure 8. Data Transfer Protocol

Start Condition

A Start condition is indicated when the bus master drives SDA from high to low while the SCL signal is high. All read and write transactions begin with a Start condition. An operation in progress can be aborted by asserting a Start condition at any time. Aborting an operation using the Start condition will ready the FM31xx for a new operation.

If the power supply drops below the specified VTP during operation, any 2-wire transaction in progress will be aborted and the system must issue a Start condition prior to performing another operation.

Stop Condition

A Stop condition is indicated when the bus master drives SDA from low to high while the SCL signal is high. All operations must end with a Stop condition. If an operation is pending when a stop is asserted, the operation will be aborted. The master must have control of SDA (not a memory read) in order to assert a Stop condition.

Data/Address Transfer

All data transfers (including addresses) take place while the SCL signal is high. Except under the two conditions described above, the SDA signal should not change while SCL is high.

Acknowledge

The Acknowledge (ACK) takes place after the 8th data bit has been transferred in any transaction. During this state the transmitter must release the SDA bus to allow the receiver to drive it. The receiver drives the SDA signal low to acknowledge receipt of the byte. If the receiver does not drive SDA low, the condition is a No-Acknowledge (NACK) and the operation is aborted.

The receiver might NACK for two distinct reasons. First is that a byte transfer fails. In this case, the NACK ends the current operation so that the part can be addressed again. This allows the last byte to be recovered in the event of a communication error.

Second and most common, the receiver does not send an ACK to deliberately terminate an operation. For example, during a read operation, the FM31xx will continue to place data onto the bus as long as the receiver sends ACKs (and clocks). When a read operation is complete and no more data is needed, the receiver must NACK the last byte. If the receiver ACKs the last byte, this will cause the FM31xx to attempt to drive the bus on the next clock while the master is sending a new command such as a Stop.

Slave Address

The first byte that the FM31xx expects after a Start condition is the slave address. As shown in figures below, the slave address contains the Slave ID, Device Select address, and a bit that specifies if the transaction is a read or a write.

The FM31xx has two Slave Addresses (Slave IDs) associated with two logical devices. To access the memory device, bits 7-4 should be set to 1010b. The other logical device within the FM31xx is the real-time clock and companion. To access this device, bits 7-4 of the slave address should be set to 1101b. A bus transaction with this slave address will not affect the memory in any way. The figures below illustrate the two Slave Addresses.

The Device Select bits allow multiple devices of the same type to reside on the 2-wire bus. The device select bits (bits 2-1) select one of four parts on a two-wire bus. They must match the corresponding value on the external address pins in order to select the device. Bit 0 is the read/write bit. A "1" indicates a read operation, and a "0" indicates a write operation.

Figure 9. Slave Address - Memory

Figure 10. Slave Address - Companion

Addressing Overview - Memory

After the FM31xx acknowledges the Slave Address, the master can place the memory address on the bus for a write operation. The address requires two bytes. This is true for all members of the family. Therefore the 4Kb and 16Kb configurations will be addressed differently from stand alone serial memories but the entire family will be upwardly compatible with no software changes.

The first is the MSB (upper byte). For a given density unused address bits are don't cares, but should be set to 0 to maintain upward compatibility.

Following the MSB is the LSB (lower byte) which contains the remaining eight address bits. The address is latched internally. Each access causes the latched address to be incremented automatically. The current address is the value that is held in the latch, either a newly written value or the address following the last access. The current address will be held as long as VDD > VTP or until a new value is written. Accesses to the clock do not affect the current memory address. Reads always use the current address. A random read address can be loaded by beginning a write operation as explained below.

After transmission of each data byte, just prior to the Acknowledge, the FM31xx increments the internal address. This allows the next sequential byte to be accessed with no additional addressing externally. After the last address is reached, the address latch will roll over to 0000h. There is no limit to the number of bytes that can be accessed with a single read or write operation.

Addressing Overview - RTC & Companion

The RTC and Processor Companion operate in a similar manner to the memory, except that it uses only one byte of address. Addresses 00h to 18h correspond to special function registers. Attempting to load addresses above 18h is an illegal condition; the FM31xx will return a NACK and abort the 2-wire transaction.

Data Transfer

After the address information has been transmitted, data transfer between the bus master and the FM31xx begins. For a read, the FM31xx will place 8 data bits on the bus then wait for an ACK from the master. If the ACK occurs, the FM31xx will transfer the next byte. If the ACK is not sent, the FM31xx will end the read operation. For a write operation, the FM31xx will accept 8 data bits from the master then send an Acknowledge. All data transfer occurs MSB (most significant bit) first.

Memory Write Operation

All memory writes begin with a Slave Address, then a memory address. The bus master indicates a write operation by setting the slave address LSB to a 0. After addressing, the bus master sends each byte of data to the memory and the memory generates an Acknowledge condition. Any number of sequential bytes may be written. If the end of the address range is reached internally, the address counter will wrap to 0000h. Internally, the actual memory write occurs after the 8th data bit is transferred. It will be complete before the Acknowledge is sent. Therefore, if the

Rev. 2.3

Oct. 2006 Page 16 of 25

user desires to abort a write without altering the memory contents, this should be done using a Start or Stop condition prior to the 8th data bit. The figures

below illustrate a single- and multiple-writes to memory.

Figure 11. Single Byte Memory Write

Figure 12. Multiple Byte Memory Write

Memory Read Operation

There are two types of memory read operations. They are current address read and selective address read. In a current address read, the FM31xx uses the internal address latch to supply the address. In a selective read, the user performs a procedure to first set the address to a specific value.

Current Address & Sequential Read

As mentioned above the FM31xx uses an internal latch to supply the address for a read operation. A current address read uses the existing value in the address latch as a starting place for the read operation. The system reads from the address immediately following that of the last operation.

To perform a current address read, the bus master supplies a slave address with the LSB set to 1. This indicates that a read operation is requested. After receiving the complete device address, the FM31xx will begin shifting data out from the current address on the next clock. The current address is the value held in the internal address latch.

Beginning with the current address, the bus master can read any number of bytes. Thus, a sequential read is simply a current address read with multiple byte transfers. After each byte the internal address counter will be incremented.

Each time the bus master acknowledges a byte, this indicates that the FM31xx should read out the next sequential byte.

There are four ways to terminate a read operation. Failing to properly terminate the read will most likely create a bus contention as the FM31xx attempts to read out additional data onto the bus. The four valid methods follow.

- 1. The bus master issues a NACK in the 9th clock cycle and a Stop in the 10th clock cycle. This is illustrated in the diagrams below and is preferred.
- 2. The bus master issues a NACK in the 9th clock cycle and a Start in the 10th.
- 3. The bus master issues a Stop in the 9th clock cycle.
- 4. The bus master issues a Start in the 9th clock cycle.

If the internal address reaches the top of memory, it will wrap around to 0000h on the next read cycle. The figures below show the proper operation for current address reads.

Selective (Random) Read

There is a simple technique that allows a user to select a random address location as the starting point for a read operation. This involves using the first

three bytes of a write operation to set the internal address followed by subsequent read operations.

To perform a selective read, the bus master sends out the slave address with the LSB set to 0. This specifies a write operation. According to the write protocol, the bus master then sends the address bytes that are loaded into the internal address latch. After the FM31xx acknowledges the address, the bus master issues a Start condition. This simultaneously aborts the write operation and allows the read command to be issued with the slave address LSB set to a 1. The operation is now a read from the current address. Read operations are illustrated below.

RTC/Companion Write Operation

All RTC and Companion writes operate in a similar manner to memory writes. The distinction is that a different device ID is used and only one byte address is needed instead of two. Figure 16 illustrates a single byte write to this device.

RTC/Companion Read Operation

As with writes, a read operation begins with the Slave Address. To perform a register read, the bus

master supplies a Slave Address with the LSB set to 1. This indicates that a read operation is requested. After receiving the complete Slave Address, the FM31xx will begin shifting data out from the current register address on the next clock. Auto-increment operates for the special function registers as with the memory address. A current address read for the registers look exactly like the memory except that the device ID is different.

The FM31xx contains two separate address registers, one for the memory address and the other for the register address. This allows the contents of one address register to be modified without affecting the current address of the other register. For example, this would allow an interrupted read to the memory while still providing fast access to an RTC register. A subsequent memory read will then continue from the memory address where it previously left off, without requiring the load of a new memory address. However, a write sequence always requires an address to be supplied.

Figure 13. Current Address Memory Read

Figure 14. Sequential Memory Read

Figure 15. Selective (Random) Memory Read

Figure 16. Byte Register Write

* Although not required, it is recommended that A5-A7 in the Register Address byte are zeros in order to preserve compatibility with future devices.

Addressing FRAM Array in the FM31xx Family

The FM31xx family includes 256Kb, 64Kb, 16Kb, and 4Kb memory densities. The following 2-byte address field is shown for each density.

Table 4. Two-Byte Memory Address

^{**} The " $V_{\rm IN} < V_{\rm DD} + 1.0 V$ " restriction does not apply to the SCL and SDA inputs which do not employ a diode to $V_{\rm DD}$. Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only, and the functional operation of the device at these or any other conditions above those listed in the operational section of this specification is not implied. Exposure to absolute maximum ratings conditions for extended periods may affect device reliability.

	A1-A0 for $V_{IN} = V_{IH} \min$	1			$M\Omega$	
V_{PFI}	Power Fail Input Reference Voltage	1.175	1.20	1.225	V	
V_{HYS}	Power Fail Input (PFI) Hysteresis (Rising)		-	100	mV	

Notes

- SCL toggling between V_{DD} -0.3V and V_{SS} , other inputs V_{SS} or V_{DD} -0.3V.
- All inputs at V_{SS} or V_{DD} , static. Stop command issued. 2.
- V_{IN} or $V_{OUT} = V_{SS}$ to V_{DD} . Does not apply to A0, A1, PFI, or /RST pins. $V_{BAK} = 3.0V$, $V_{DD} < 2.4V$, oscillator running, CNT1-2 at V_{BAK} . 3.
- 4.
- /RST is asserted low when $V_{DD} \le V_{TP}$. 5.
- The minimum V_{DD} to guarantee the level of /RST remains a valid V_{OL} level.
- Full complete operation. Supervisory circuits, RTC, etc operate to lower voltages as specified.
- Includes /RST input detection of external reset condition to trigger driving of /RST signal by FM31xx.
- The VBAK trickle charger automatically regulates the maximum voltage on this pin for capacitor backup applications.
- 10. V_{BAK} will source current when trickle charge is enabled (VBC bit=1), $V_{DD} > V_{BAK}$, and $V_{BAK} < V_{BAK}$ max.

AC Parameters ($T_A = -40^{\circ}$ C to $+85^{\circ}$ C $V_{DD} = 2.7$ V to 5.5V $C_L = 100$ pF unless otherwise specified)

Symbol	Parameter	Min	Max	Min	Max	Min	Max	Units	Notes

Revision History

Revision	Date	Summary
0.2	5/22/03	Initial release.
0.21	11/25/03	Fixed package drawing dimensions.
1.0	3/30/04	Changed product status to Preliminary. Added V _{TP} and V _{PFI} parameters in DC
		Operating table. Changed V _{HYS} limits. Added "green" package.
1.0a	4/27/04	Changed V_{PFI} limits, changed V_{TF} and V_{TR} conditions and measurement units,
		created additional I _{SB} specification, and added board layout section.
2.0	10/25/04	Changed to Pre-Production status. Added text to Trickle Charger section.
		Improved spec limits on V _{TP} , V _{PFI} , and V _{HYS} parameters and changed V _{IH} max
		limits in DC Operating table. Added companion register table with default
		values. Added Package Marking Scheme and board footprint. Devices marked
		with Date Codes 0440 and higher comply with the revision of the datasheet.
2.1	12/8/04	Changed description of POR flag and manual reset (pg. 5, 13). Added notes to
		Absolute Maximum Ratings.
2.2	11/2/05	Rewrote section on battery backup. Added comment about unused CNT pins.
2.3	10/2/06	Removed -S packaging option which is Not Recommended for New Designs.
		Added ESD and MSL ratings which are valid for Date Codes 0440 and higher.
