### DESCRIPTION:

The IDT5V2528 is a high performance, low-skew, low-jitter, phase-lock loop (PLL) clock driver. It uses a PLL to precisely align, in both frequency and phase, the feedback (FBOUT) output to the clock (CLK) input signal.

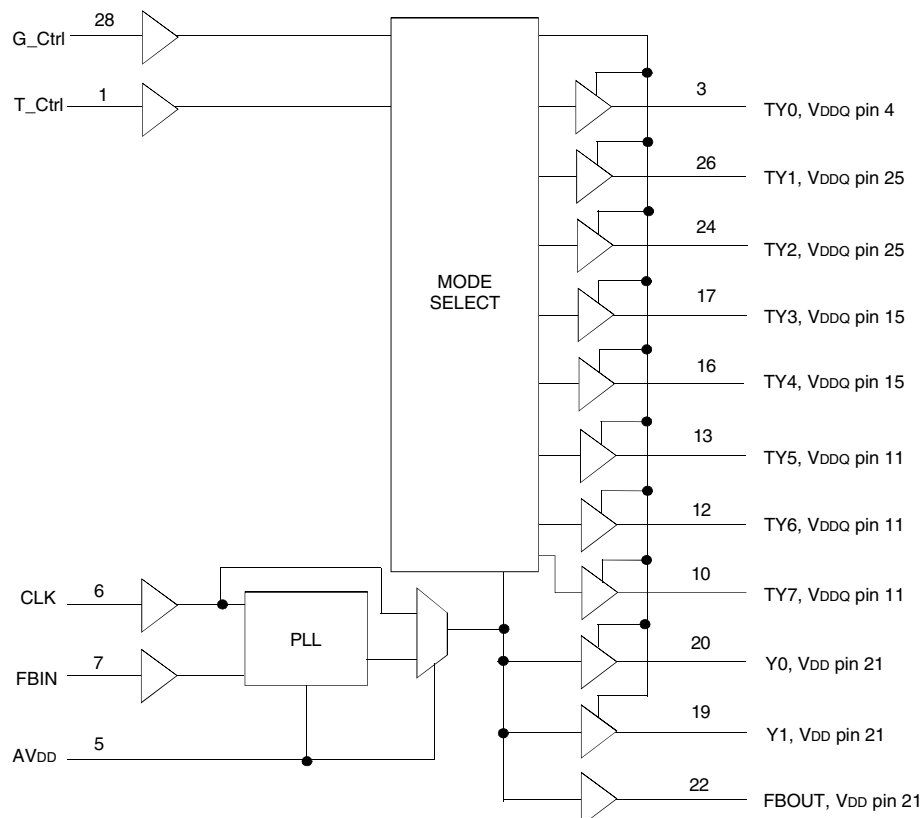

The IDT5V2528 inputs, PLL core, Y<sub>0</sub>, Y<sub>1</sub>, and FBOUT buffers operate from the 3.3V  $V_{DD}$  and  $AV_{DD}$  power supply pins.

One bank of ten outputs provide low-skew, low-jitter copies of CLK. Of the ten outputs, up to seven may be configured for 2.5V or 3.3V LVTTTL outputs. The number of 2.5V outputs is controlled by 3-level input signals G\_Ctrl and T\_Ctrl, and by connecting the appropriate  $V_{DDQ}$  pins to 2.5V or 3.3V. The 3-level input signals may be hard-wired to high-mid-low levels. Output signal duty cycles are adjusted to 50 percent, independent of the duty cycle at CLK. The outputs can be enabled or disabled via the G\_Ctrl input. When the G\_Ctrl input is mid or high, the outputs switch in phase and frequency with CLK; when the G\_Ctrl is low, all outputs (except FBOUT) are disabled to the logic-low state.

Unlike many products containing PLLs, the IDT5V2528 does not require external RC networks. The loop filter for the PLL is included on-chip, minimizing component count, board space, and cost.

Because it is based on PLL circuitry, the IDT5V2528 requires a stabilization time to achieve phase lock of the feedback signal to the reference signal. This stabilization time is required, following power up and application of a fixed-frequency, fixed-phase signal at CLK, as well as following any changes to the PLL reference or feedback signals. The PLL can be bypassed for test purposes by strapping  $AV_{DD}$  to ground.

### NOTES:

- Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.
- The input and output negative-voltage ratings may be exceeded if the input and output clamp-current ratings are observed.
- The maximum package power dissipation is calculated using a junction temperature of 150°C and a board trace length of 750 mils.

GND	2, 9, 14, 18 23, 27	Ground	Ground

### NOTES:

1. CLK must have a fixed frequency and fixed phase for the PLL to obtain phase lock. Once the circuit is powered up and a valid CLK signal is applied, a stabilization time of 1ms is required for the PLL to phase lock the feedback signal to the reference signal.
2. 3-level inputs will float to MID logic level if left unconnected.
3. AVDD can be used to bypass the PLL for test purposes. When AVDD is strapped to ground, PLL is bypassed and CLK is buffered directly to the outputs.

### NOTES:

- For conditions shown as Min or Max, use the appropriate value specified under recommended operating conditions.
- These inputs are normally wired to V<sub>DD</sub>, GND, or left floating. Internal termination resistors bias floating inputs to V<sub>DD</sub>/2. If these inputs are switched, the function and timing of the outputs may be glitched, and the PLL may require an additional t<sub>LOCK</sub> time before all datasheet limits are achieved.

**NOTE:**  
1. Time required for the integrated PLL circuit to obtain phase lock of its feedback signal to its reference signal. For phase lock to be obtained, a fixed-frequency, fixed-phase reference signal must be present at CLK. Until phase lock is obtained, the specifications for propagation delay, skew, and jitter parameters given in the switching characteristics table are not applicable.

**NOTES:**

1. All inputs pulses are supplied by generators having the following characteristics:  $\text{PRR} \leq 100\text{MHz}$   $Z_0 = 50\Omega$ ,  $t_r \leq 1.2 \text{ ns}$ ,  $t_f \leq 1.2 \text{ ns}$ .
2.  $C_L$  includes probe and jig capacitance.
3. The outputs are measured one at a time with one transition per measurement.
4. Phase error measurements require equal loading at outputs Y, TY, and FBOU.  $C_F = C_L - C_{\text{FBIN}} - C_{\text{PCBtrace}}$ ;  $C_{\text{FBIN}} \cong 5\text{pF}$ .
