

# 14-Bit, 135ksps, Single-Supply ADCs with Bipolar Analog Input Range

## General Description

The MAX1156/MAX1158/MAX1174 14-bit, low-power, successive-approximation analog-to-digital converters (ADCs) feature automatic power-down, a factory-trimmed internal clock, and a byte-wide parallel interface. The devices operate from a single +4.75V to +5.25V analog supply and feature a separate digital supply input for direct interface with +2.7V to +5.25V digital logic.

The MAX1156 accepts a 0 to +10V analog input voltage range. The MAX1158 accepts a  $\pm 10V$  bipolar analog input voltage range, while the MAX1174 accepts a  $\pm 5V$  bipolar analog input voltage range. All devices consume no more than 26.5mW at a sampling rate of 135ksps when using an external reference, and 31mW when using the internal +4.096V reference. AutoShutdown™ reduces supply current to 0.4mA (typ) at 10ksps.

The MAX1156/MAX1158/MAX1174 are ideal for high-performance, battery-powered, data-acquisition applications. Excellent AC performance (THD = -100dB) and DC accuracy ( $\pm 1$ LSB INL) make the MAX1156/MAX1158/MAX1174 ideal for industrial process control, instrumentation, and medical applications.

The MAX1156/MAX1158/MAX1174 are available in a 20-pin TSSOP package and are fully specified over the -40°C to +85°C extended temperature range and the 0°C to +70°C commercial temperature range.

## Applications

Temperature Sensing and Monitoring  
Industrial Process Control  
I/O Modules  
Data-Acquisition Systems  
Precision Instrumentation

*Pin Configuration appears at end of data sheet.*

*AutoShutdown is a trademark of Maxim Integrated Products, Inc.*

## Features

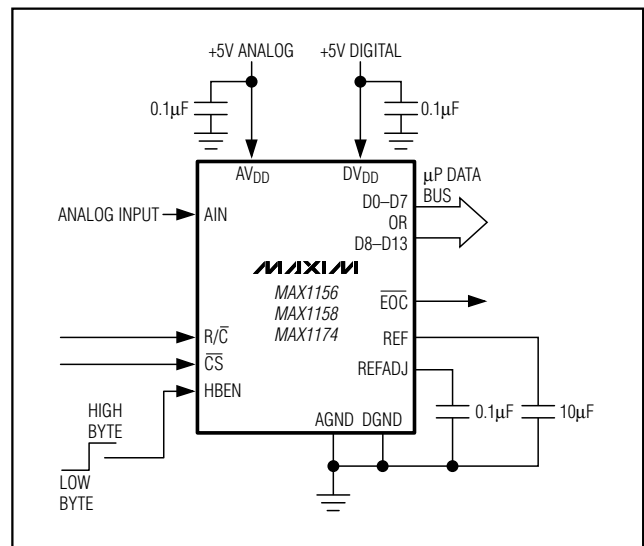

- ◆ Byte-Wide Parallel Interface
- ◆ Analog Input Voltage Range:  $\pm 10V$ ,  $\pm 5V$ , 0 to 10V
- ◆ Single +4.75V to +5.25V Analog Supply Voltage
- ◆ Interface with +2.7V to +5.25V Digital Logic
- ◆  $\pm 1$ LSB INL (max)
- ◆  $\pm 1$ LSB DNL (max)
- ◆ Low Supply Current (max)
  - 2.9mA (External Reference)
  - 3.8mA (Internal Reference)
  - 5 $\mu$ A AutoShutdown Mode
- ◆ Small Footprint
- ◆ 20-Pin TSSOP Package

## Ordering Information

PART	TEMP RANGE	PIN-PACKAGE	INPUT VOLTAGE RANGE
MAX1156ACUP	0°C to +70°C	20 TSSOP	0 to +10V
MAX1156BCUP	0°C to +70°C	20 TSSOP	0 to +10V
MAX1156AEUP	-40°C to +85°C	20 TSSOP	0 to +10V
MAX1156BEUP	-40°C to +85°C	20 TSSOP	0 to +10V

*Ordering Information continued at end of data sheet.*

## Typical Operating Circuit

## Pin Description

PIN	NAME	FUNCTION
1	D4/D12	Three-State Digital Data Output
2	D5/D13	Three-State Digital Data Output. D13 is the MSB.
3	D6/0	Three-State Digital Data Output
4	D7/0	Three-State Digital Data Output
5	$R/\overline{C}$	Read/Convert Input. Power up and put the MAX1156/MAX1158/MAX1174 in acquisition mode by holding $R/\overline{C}$ low during the first falling edge of $\overline{CS}$ . During the second falling edge of $\overline{CS}$ , the level on $R/\overline{C}$ determines whether the reference and reference buffer power down or remain on after conversion. Set $R/\overline{C}$ high during the second falling edge of $\overline{CS}$ to power down the reference and buffer, or set $R/\overline{C}$ low to leave the reference and buffer powered up. Set $R/\overline{C}$ high during the third falling edge of $\overline{CS}$ to put valid data on the bus.
6	$\overline{EOC}$	End of Conversion. $\overline{EOC}$ drives low when conversion is complete.
7	$AV_{DD}$	Analog Supply Input. Bypass with a $0.1\mu F$ capacitor to AGND.
8	AGND	Analog Ground. Primary analog ground (star ground).
9	AIN	Analog Input
10	AGND	Analog Ground. Connect pin 10 to pin 8.
11	REFADJ	Reference Buffer Output. Bypass REFADJ with a $0.1\mu F$ capacitor to AGND for internal reference mode. Connect REFADJ to $AV_{DD}$ to select external reference mode.
12	REF	Reference Input/Output. Bypass REF with a $10\mu F$ capacitor to AGND for internal reference mode. External reference input when in external reference mode.

# 14-Bit, 135ksps, Single-Supply ADCs with Bipolar Analog Input Range

MAX1156/MAX1158/MAX1174

## Pin Description (continued)

PIN	NAME	FUNCTION
13	HBEN	High-Byte Enable Input. Used to multiplex the 14-bit conversion result. 1: Most significant byte available on the data bus. 0: Least significant byte available on the data bus.
14	$\overline{CS}$	Convert Start. The first falling edge of $\overline{CS}$ powers up the device and enables acquire mode when R/ $\overline{C}$ is low. The second falling edge of $\overline{CS}$ starts conversion. The third falling edge of $\overline{CS}$ loads the result onto the bus when R/ $\overline{C}$ is high.
15	DGND	Digital Ground
16	DVDD	Digital Supply Voltage. Bypass with a 0.1 $\mu$ F capacitor to DGND.
17	D0/D8	Three-State Digital Data Output. D0 is the LSB.
18	D1/D9	Three-State Digital Data Output
19	D2/D10	Three-State Digital Data Output
20	D3/D11	Three-State Digital Data Output

Figure 1. Load Circuits

## Detailed Description

### Converter Operation

The MAX1156/MAX1158/MAX1174 use a successive-approximation (SAR) conversion technique with an inherent track-and-hold (T/H) stage to convert an analog input into a 14-bit digital output. Parallel outputs provide a high-speed interface to microprocessors ( $\mu$ Ps). The *Functional Diagram* shows a simplified internal architecture of the MAX1156/MAX1158/MAX1174. Figure 3 shows a typical application circuit for the MAX1156/MAX1158/MAX1174.

### Analog Input Input Scaler

The MAX1156/MAX1158/MAX1174 have an input scaler, which allows conversion of true bipolar input voltages and input voltages greater than the power supply, while operating from a single +5V analog supply. The input scaler attenuates and shifts the analog input to match the input range of the internal DAC. The MAX1156 has a unipolar input voltage range of 0 to +10V. The MAX1158 input voltage range is  $\pm 10$ V while the MAX1174 input voltage range is  $\pm 5$ V. Figure 4 shows the equivalent input circuit of the MAX1156/MAX1158/MAX1174. This circuit limits the current going into or out of AIN to less than 1.8mA.

### Track and Hold (T/H)

In track mode, the internal hold capacitor acquires the analog signal (see Figure 4). In hold mode, the T/H switches open and the capacitive DAC samples the analog input. During the acquisition, the analog input (AIN) charges capacitor  $C_{HOLD}$ . The acquisition ends on the second falling edge of  $\overline{CS}$ . At this instant, the T/H switches open. The retained charge on  $C_{HOLD}$  represents a sample of the input. In hold mode, the capacitive DAC adjusts during the remainder of the conversion time to restore node T/H OUT to zero within the limits of 14-bit resolution. Force  $\overline{CS}$  low to put valid data on the bus after conversion is complete.

# 14-Bit, 135ksp/s, Single-Supply ADCs with Bipolar Analog Input Range

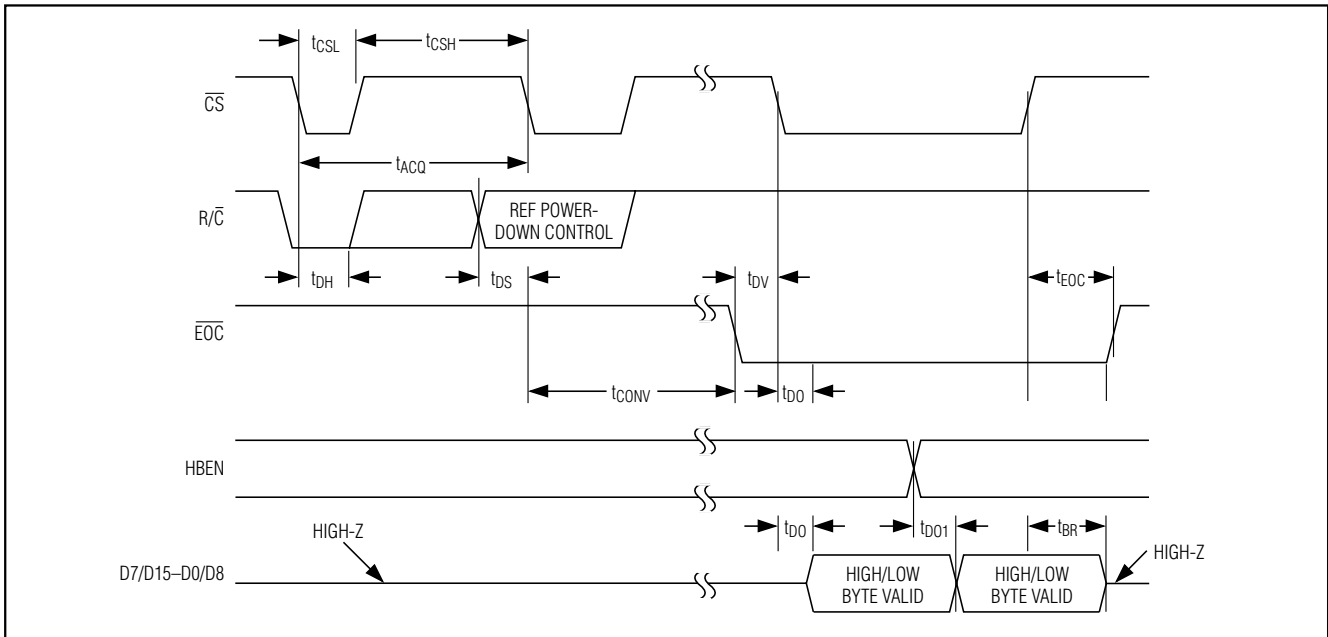

Figure 2. MAX1156/MAX1158/MAX1174 Timing Diagram

### Power-Down Modes

Select standby mode or shutdown mode with the R/C bit during the second falling edge of CS (see the *Selecting Standby or Shutdown Mode* section). The MAX1156/MAX1158/MAX1174 automatically enter either standby mode (reference and buffer on) or shutdown (reference and buffer off) after each conversion, depending on the status of R/C during the second falling edge of CS.

### Internal Clock

The MAX1156/MAX1158/MAX1174 generate an internal conversion clock to free the microprocessor from the burden of running the SAR conversion clock. Total conversion time ( $t_{CONV}$ ) after entering hold mode (second falling edge of CS) to end of conversion (EOC) falling is 4.7µs (max).

## Applications Information

### Starting a Conversion

CS and R/C control acquisition and conversion in the MAX1156/MAX1158/MAX1174 (see Figure 2). The first falling edge of CS powers up the device and puts it in acquire mode if R/C is low. The convert start is ignored if R/C is high. The MAX1156/MAX1158/MAX1174 need at least 12ms ( $C_{REFADJ} = 0.1\mu\text{F}$ ,  $C_{REF} = 10\mu\text{F}$ ) for the internal reference to wake up and settle before starting the conversion, if powering up from shutdown.

Figure 3. Typical Application Circuit for the MAX1156/MAX1158/MAX1174

# 14-Bit, 135ksps, Single-Supply ADCs with Bipolar Analog Input Range

MAX1156/MAX1158/MAX1174

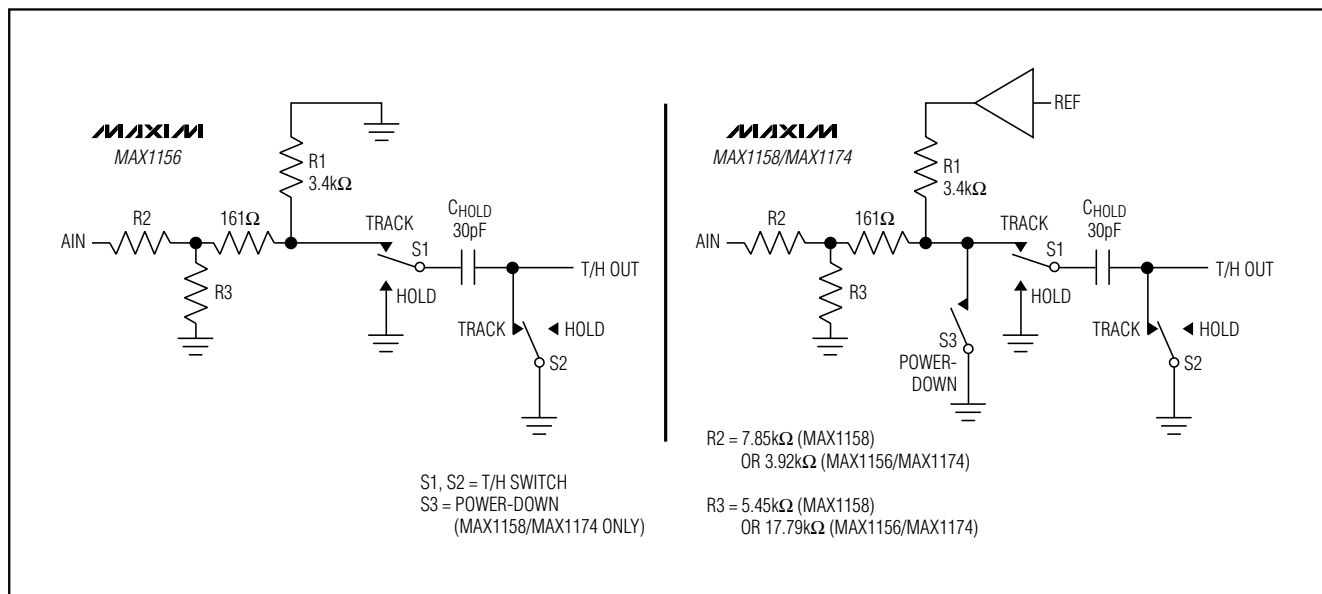

Figure 4. Equivalent Input Circuit

## Selecting Standby or Shutdown Mode

The MAX1156/MAX1158/MAX1174 have a selectable standby or low-power shutdown mode. In standby mode, the ADC's internal reference and reference buffer do not power down between conversions, eliminating the need to wait for the reference to power up before performing the next conversion. Shutdown mode powers down the reference and reference buffer after completing a conversion. The reference and reference buffer require a minimum of 12ms ( $C_{REFADJ} = 0.1\mu\text{F}$ ,  $C_{REF} = 10\mu\text{F}$ ) to power up and settle from shutdown.

The state of  $R/\overline{C}$  at the second falling edge of  $\overline{CS}$  selects which power-down mode the MAX1156/MAX1158/MAX1174 enter upon conversion completion. Holding  $R/\overline{C}$  low causes the MAX1156/MAX1158/MAX1174 to enter standby mode. The reference and buffer are left on after the conversion completes.  $R/\overline{C}$  high causes the MAX1156/MAX1158/MAX1174 to enter shutdown mode and power down the reference and buffer after conversion (see Figures 5 and 6). Set the voltage at  $R/\overline{C}$  high during the second falling edge of  $\overline{CS}$  to realize the lowest current operation.

## Standby Mode

While in standby mode, the supply current is less than 3.7mA (typ). The next falling edge of  $\overline{CS}$  with  $R/\overline{C}$  low causes the MAX1156/MAX1158/MAX1174 to exit standby mode and begin acquisition. The reference and reference buffer remain active to allow quick turn-on time.

## Shutdown Mode

In shutdown mode, the reference and reference buffer are shut down between conversions. Shutdown mode reduces supply current to 0.5μA (typ) immediately after the conversion. The next falling edge of  $\overline{CS}$  with  $R/\overline{C}$  low causes the reference and buffer to wake up and enter acquisition mode. To achieve 14-bit accuracy, allow 12ms ( $C_{REFADJ} = 0.1\mu\text{F}$ ,  $C_{REF} = 10\mu\text{F}$ ) for the internal reference to wake up.

## Internal and External Reference

### Internal Reference

The internal reference of the MAX1156/MAX1158/MAX1174 is internally buffered to provide +4.096V output at REF. Bypass REF to AGND and REFADJ to AGND with 10μF and 0.1μF, respectively. Sink or source current at REFADJ to make fine adjustments to the internal reference. The input impedance of REFADJ is nominally 5kΩ. Use the circuit of Figure 7 to adjust the internal reference to ±1.5%.

# 14-Bit, 135ksps, Single-Supply ADCs with Bipolar Analog Input Range

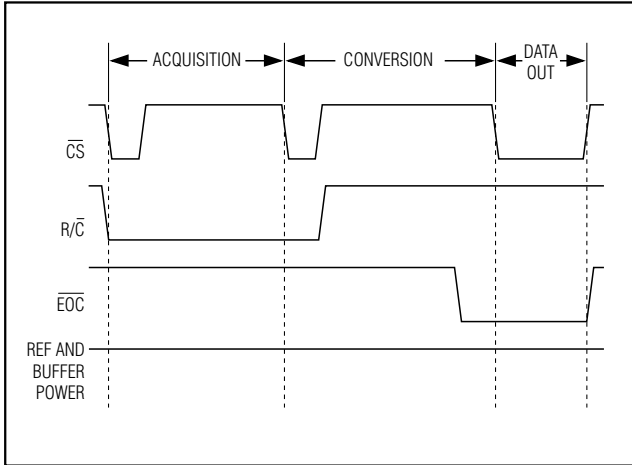

Figure 5. Selecting Standby Mode

Figure 6. Selecting Shutdown Mode

### External Reference

An external reference can be placed at either the input (REFADJ) or the output (REF) of the MAX1156/MAX1158/MAX1174's internal buffer amplifier. Using the buffered REFADJ input makes buffering the external reference unnecessary. The input impedance of REFADJ is typically 5k $\Omega$ . The internal buffer output must be bypassed at REF with a 10 $\mu$ F capacitor.

Connect REFADJ to AV<sub>DD</sub> to disable the internal buffer. Directly drive REF using an external 3.8V to 4.2V reference. During conversion, the external reference must be able to drive 100 $\mu$ A of DC load current and have an output impedance of 10 $\Omega$  or less.

For optimal performance, buffer the reference through an op amp and bypass REF with a 10 $\mu$ F capacitor. Consider the MAX1156/MAX1158/MAX1174's equivalent input noise (0.32LSB) when choosing a reference.

### Reading the Conversion Result

$\overline{\text{EOC}}$  is provided to flag the microprocessor when a conversion is complete. The falling edge of  $\overline{\text{EOC}}$  signals that the data is valid and ready to be output to the bus. D0–D13 are the parallel outputs of the MAX1156/MAX1158/MAX1174. These three-state outputs allow for direct connection to a microcontroller I/O bus. The outputs remain high-impedance during acquisition and conversion. Data is loaded onto the output bus with the third falling edge of  $\overline{\text{CS}}$  with R/ $\overline{\text{C}}$  high (after t<sub>DO</sub>). Bringing  $\overline{\text{CS}}$  high forces the output bus back to high impedance. The MAX1156/MAX1158/MAX1174 then wait for the next falling edge of  $\overline{\text{CS}}$  to start the next conversion cycle (see Figure 2).

HBEN toggles the output between the high/low byte. The low byte is loaded onto the output bus when HBEN is low and the high byte is on the bus when HBEN is high. The two MSBs of the high byte are always zero.

### Transfer Function

Figures 8, 9, and 10 show the MAX1156/MAX1158/MAX1174 output transfer functions. The MAX1158 and MAX1174 outputs are coded in offset binary, while the MAX1156 is coded in standard binary.

### Input Buffer

Most applications require an input buffer amplifier to achieve 14-bit accuracy and prevent loading the source. Switch the channels immediately after acquisition, rather than near the end of or after a conversion, when the input signal is multiplexed. This allows more time for the input buffer amplifier to respond to a large step-change in input signal. The input amplifier must have a high enough slew rate to complete the required output voltage change before the beginning of the acquisition time. Figure 11 shows an example of this circuit using the MAX427.

Figures 12a and 12b show how the MAX1158 and MAX1174 analog input current varies depending on whether the chip is operating or powered down. The part is fully powered down between conversions if the voltage at R/ $\overline{\text{C}}$  is set high during the second falling edge of  $\overline{\text{CS}}$ . The input current abruptly steps to the powered up value at the start of acquisition. This step in the input current can disrupt the ADC input, depending on the driving circuit's output impedance at high frequencies. If the driving circuit cannot fully settle by

Figure 10. MAX1174 Transfer Function

the end of acquisition, the accuracy of the system can be compromised. To avoid this situation, increase the acquisition time, use a driving circuit that can settle within  $t_{ACQ}$ , or leave the MAX1158/MAX1174 powered up by setting the voltage at  $R/\overline{C}$  low during the second falling edge of  $\overline{CS}$ .

### Layout, Grounding, and Bypassing

For best performance, use printed circuit boards. Do not run analog and digital lines parallel to each other, and do not layout digital signal paths underneath the

ADC package. Use separate analog and digital ground planes with only one point connecting the two ground systems (analog and digital) as close to the device as possible.

Route digital signals far away from sensitive analog and reference inputs. If digital lines must cross analog lines, do so at right angles to minimize coupling digital noise onto the analog lines. If the analog and digital sections share the same supply, isolate the digital and analog

supply by connecting them with a low value (10Ω) resistor or ferrite bead.

The ADC is sensitive to high-frequency noise on the AVDD supply. Bypass AVDD to AGND with a 0.1μF capacitor in parallel with a 1μF to 10μF low-ESR capacitor with the smallest capacitor closest to the device. Keep capacitor leads short to minimize stray inductance.

## Definitions

### Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best-straight-line fit or a line drawn between the endpoints of the transfer function, once offset and gain errors have been nullified. The static linearity parameters for the MAX1156/MAX1158/MAX1174 are measured using the endpoint method.

### Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step-width and the ideal value of 1LSB. A DNL error specification of 1LSB guarantees no missing codes and a monotonic transfer function.

## Signal-to-Noise Ratio

For a waveform perfectly reconstructed from digital samples, signal-to-noise ratio (SNR) is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal, theoretical minimum analog-to-digital noise is caused by quantization noise error only and results directly from the ADC's resolution (N bits):

$$\text{SNR} = (6.02 \times N + 1.76) \text{ dB}$$

where  $N = 14$  bits.

In reality, there are other noise sources besides quantization noise; thermal noise, reference noise, clock jitter, etc. SNR is computed by taking the ratio of the RMS signal to the RMS noise, which includes all spectral components minus the fundamental, the first five harmonics, and the DC offset.

## Signal-to-Noise Plus Distortion

Signal-to-noise plus distortion (SINAD) is the ratio of the fundamental input frequency's RMS amplitude to the RMS equivalent of all the other ADC output signals.

$$\text{SINAD(dB)} = 20 \times \log \left[ \frac{\text{Signal}_{\text{RMS}}}{(\text{Noise} + \text{Distortion})_{\text{RMS}}} \right]$$

## Effective Number of Bits

Effective number of bits (ENOB) indicates the global accuracy of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of quanti-

zation noise only. With an input range equal to the full-scale range of the ADC, calculate the effective number of bits as follows:

$$\text{ENOB} = \frac{\text{SINAD} - 1.76}{6.02}$$

## Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the RMS sum of the first five harmonics of the input signal to the fundamental itself. This is expressed as:

$$\text{THD} = 20 \times \log \left[ \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2}}{V_1} \right]$$

where  $V_1$  is the fundamental amplitude and  $V_2$  through  $V_5$  are the 2nd- through 5th-order harmonics.

## Spurious-Free Dynamic Range

Spurious-free dynamic range (SFDR) is the ratio of the RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next largest frequency component.
